- Explain common emotional responses.
- Explain the need for monitoring health practices.
- Emphasize protective precautions to decrease risk for exposure to infection(s) as necessary.
- Advise patient about ways to prevent or minimize acquisition of upper respiratory infection and influenza: frequent hand washing, avoiding crowds, receiving influenza and other vaccinations as appropriate
- For patient of childbearing age, provide information about managing future pregnancies to reduce risk of HIV transmission to fetus.
- Provide personal drug therapy plan in the patient's preferred method of learning.
- Inform patient that certain medications (including OTC), foods, and herbal products may interact with antiretrovirals.
- Establish patient/family partnership in the plan.

Self-Administration

- Assist patient to develop a system for taking correct dose of correct medications at correct time.
- Counsel patient about importance of having an adequate supply of medication to avoid interruption in dosing schedule. Omission of drugs may result in deterioration of patient's condition.
- For pediatric patients unable to swallow medications, teach swallowing techniques.

Side Effects

- Advise patient about what symptoms to report promptly to health care provider.
- Discuss possible medication side effects and strategies to manage them.

Diet

- Advise patient to eat a variety of foods, to avoid raw eggs and raw fish, and to cook meats to correct temperature.
- Advise patient about how to minimize side effects (e.g., take specific drug with food).
- Discuss diet of banana, rice, applesauce, and toast for management of diarrhea.

Cultural Considerations

- Know that some cultural groups may believe the drug AZT to be harmful.
- Be aware that some cultures pressure women to reproduce regardless of health status.
- Remember that HIV remains a highly stigmatized disease in many cultures.
- Know that some religions prohibit use of contraception, especially male condom use.
- Some members of certain cultural groups may distrust health care providers and refuse treatment regimens that include research.

Evaluation

- Evaluate the effectiveness of the antiretroviral therapy.
- Determine whether the viral load is undetectable; assess for increase in CD4 count.
- Evaluate medication adherence.
- Evaluate adherence with behaviors that decrease the possibility of HIV transmission such as practicing safer sex, not sharing drug works, and participating in needle exchange programs if available and applicable.

In addition to patient assessment, education, and advocacy, nurses should identify problems that require additional investigation and research. Because of the individual needs of HIV/AIDS patients, research on strategies to promote adherence is needed. Best practices for adherence should be identified.

The nurse's role with research is also needed with clinical trials. Accurate data collection, recordkeeping, and attention to detail are necessary. Whenever medication regimens change, nurses should contribute to the ongoing evaluation of medication/regimen side effects and adverse event reporting.

OPPORTUNISTIC INFECTIONS

As HIV infection advances, patients are more vulnerable to infections and malignancies that are called **opportunistic infections** because they take advantage of the opportunity offered by a weakened immune system. Since the introduction of HAART, there has been a dramatic reduction in the incidence of OIs among HIV-positive patients receiving these medications. Although hospitalizations and deaths have decreased, OIs remain a leading cause of morbidity and mortality in HIV-infected persons. Prevention and treatment of OIs remain essential.

The most common HIV-related OIs include the following:

- Bacterial: tuberculosis, bacterial pneumonia, septicemia
- Protozoal: toxoplasmosis, cryptosporidiosis, leishmaniasis
- Fungal: *Pneumocystis jiroveci* pneumonia, candidiasis, cryptococcosis
- Viral: cytomegalovirus, herpes simplex, herpes zoster
- HIV-associated malignancies: Kaposi sarcoma, lymphoma, squamous cell carcinoma

Different conditions typically occur at different stages of HIV infection. Common with a CD4 count below 350 cells/mL are the following:

- Herpes simplex virus causes ulcers/vesicles in the mouth or genitals. Treatment includes acyclovir, famciclovir, or valacyclovir.
- Herpes zoster virus causes shingles. Shingles has a greater than 15-fold higher incidence for HIV-infected patients. Treatment includes acyclovir, famciclovir, or valacyclovir.
- Herpes simplex and herpes zoster are also capable of causing retinitis and encephalitis, which can be life-threatening.
- TB infection predominantly affects the lungs but can affect other organs, such as the bowel, brain, lining of the heart or lungs, or lining of the CNS. The CD4 cell count is not a reliable predictor of increased risk for TB disease. Treatment includes isoniazid, pyridoxine, rifampin, pyrazinamide, and ethambutol.
- Kaposi sarcoma causes dark blue lesions that can occur in a variety of locations, including the skin, mucous membranes, gastrointestinal tract, lungs, or lymph nodes; they usually appear early in the course of HIV infection. Treatment depends on the symptoms and location. For local lesions, vinblastine has been used. Radiotherapy has been used in delicate sites such as the eyes. Chemotherapy is the preferred treatment for severe widespread disease.

Common with a CD4 count below 200 cells/mL are the following:

- *Candida* esophagitis is a painful yeast infection of the esophagus. Oropharyngeal candidiasis is characterized by painless, creamy white, plaquelike lesions of the buccal or oropharyngeal mucosa or tongue surface. Fluconazole or itraconazole are effective treatments.
- Bacillary angiomatosis is skin lesions caused by *Bartonella,* usually acquired from cat scratches. Treatment includes erythromycin, clarithromycin, azithromycin, and doxycycline.
- ***Pneumocystis jiroveci* pneumonia** is caused by a fungus that shares biologic characteristics with protozoa that infects the lungs. Symptoms are mainly pneumonia, along with fever and respiratory symptoms such as dry cough, chest pain, and dyspnea. Treatment includes TMP-SMX, clindamycin, or oral primaquine.

Common with a CD4 count below 100 cells/mL are the following:

- Cryptococcal meningitis infection of the lining of the brain by a yeast
- AIDS dementia
- Toxoplasmosis encephalitis caused by a protozoan found in uncooked meat and cat feces. Infecting the brain, it can cause headache, confusion, motor weakness, and fever. If left untreated, the disease progression results in seizures, stupor, and coma. Treatment includes pyrimethamine, sulfadiazine, and clindamycin. Leucovoran is added to decrease hematologic toxicities associated with pyrimethamine therapy.
- Progressive multifocal leukoencephalopathy, a viral disease of the brain that results in a severe decline in cognitive and motor functions
- Wasting syndrome causing extreme weight loss and loss of appetite
- Cryptosporidiosis caused by protozoan parasite *cryptosporidium* infecting the small bowel mucosa, large bowel, and extraintestinal site. Symptoms include profuse, nonbloody, watery diarrhea, often with nausea, vomiting, and lower abdominal cramping.

Common with a CD4 count below 50 cells/mL are the following:

- *Mycobacterium avium* complex (MAC) is a blood infection caused by bacteria related to tuberculosis. MAC generally affects multiple organs, with symptoms including fever, night sweats, weight loss, fatigue, diarrhea, and abdominal pain. Localized syndromes include pneumonitis, osteomyelitis, skin or soft-tissue abscesses, or CNS infections. Treatment includes clarithromycin, azithromycin, ethambutol, and rifabutin.
- Cytomegalovirus infection is a virus infecting the whole body, but it most commonly appears as retinitis causing blurred vision. It can lead to blindness. Cytomegalovirus can also affect other organs, causing fever, diarrhea, nausea, pneumonia-like symptoms, and dementia. Treatment includes ganciclovir, valganciclovir, foscarnet, or cidofovir.

ANTIRETROVIRAL THERAPY IN PREGNANCY

Optimal drug therapy should be used for women of reproductive age and for those who are pregnant. When initiating ART for women of reproductive age, the criteria for starting therapy and the goals of treatment are identical to those for other adults and adolescents. Because of considerations related to the prevention of HIV transmission to the fetus during pregnancy, the timing of initiation of treatment and the selection of regimens for pregnant patients may differ from those nonpregnant adults or adolescents.

For pregnant patients, an additional goal is to prevent mother-to-child transmission, with viral suppression to at least 1000 copies/mL or less to reduce the risk of transmission of HIV to the fetus or neonate. A patient infected with HIV can transmit the virus during pregnancy, labor, and delivery, and through breastfeeding. If no preventive drugs are taken and breastfeeding is practiced, the chance of the infant becoming infected is 25%. ART medications reduce the risk of transmission to less than 2% when combined with other interventions (e.g., formula feeding).

ART is recommended in all pregnant patients who test positive for HIV infection, regardless of virologic, immunologic, or clinical parameters for the purpose of preventing mother-to-child transmission of HIV. Combination drug therapy is considered the standard of care for both treatment of maternal HIV infection and prophylaxis to reduce the risk for perinatal HIV transmission.

For the HIV-infected woman of childbearing age who is not pregnant, initiate ART per adult treatment guidelines. If the patient expresses interest in becoming pregnant and efavirenz is considered as part of the antiretroviral regimen, a risk-benefit discussion must take place regarding the risk of neural tube defects related to efavirenz in the first 5 to 6 weeks of pregnancy.

For the HIV-infected patient receiving ART who becomes pregnant, continue the current regimen if it is successfully suppressing viremia. As stated, in regimens containing efavirenz, the risk of neural tube defects is restricted to the first 5 to 6 weeks of pregnancy. Pregnancy is often not recognized during this time. Unnecessary changes in ART during pregnancy may be associated with loss of viral control and increased risk of perinatal transmission. Efavirenz can be continued in pregnant patients receiving an efavirenz-based regimen who present for antenatal care in the first trimester, provided the regimen produces virologic suppression.

For the HIV-infected pregnant patient who is not on antiretroviral agents, ART should be initiated for prophylaxis of perinatal transmission. Zidovudine (ZDV) as a component of the regimen is recommended when possible. ART may be delayed until after the first trimester.

ART is continued during the intrapartum period (ZDV is given as a continuous infusion, while other agents are given orally). For the infant, ZDV is given for 6 weeks starting 6 to 12 hours after birth (see Prototype Drug Chart 35-1 for dosage).

Clinicians treating pregnant patients infected with HIV are encouraged to report cases of prenatal exposure to antiretroviral drugs to the Antiretroviral Pregnancy Registry at *www.apregistry.com*. The registry collects data regarding antiretroviral exposure during pregnancy to assess potential teratogenicity.

OCCUPATIONAL EXPOSURE TO HIV AND POSTEXPOSURE PROPHYLAXIS

Treatment regimens after percutaneous exposure to HIV are called **postexposure prophylaxis** (PEP) regimens. Many PEP regimens are available, with varying degrees of tolerability and probability of patients completing 4 weeks of treatment. Basic and expanded PEP regimens are described in Table 35-4; HIV PEP resources and registries are shown in Box 35-1. PEP management of potential HIV exposure should be

initiated within hours of the event and continued for 4 weeks. Health care workers taking PEP have reported adverse reactions at rates of 17% to 47%, with the most common reactions being nausea, malaise, and fatigue.

TABLE 35-4 BASIC AND EXPANDED POSTEXPOSURE PROPHYLAXIS REGIMENS

REGIMEN	DRUG REGIMEN
Basic	zidovudine (Retrovir) + lamivudine (Epivir) available as Combivir zidovudine: 300 mg b.i.d. or 200 mg t.i.d. lamivudine: 300 mg once daily or 150 mg b.i.d. Combivir: 1 tablet b.i.d. zidovudine + emtricitabine (Emtriva) zidovudine: 300 mg b.i.d. or 200 mg t.i.d. emtricitabine: 200 mg once daily tenofovir (Viread) + lamivudine tenofovir: 300 mg once daily lamivudine: 300 mg once daily or 150 mg b.i.d. tenofovir + emtricitabine available as Truvada tenofovir: 300 mg once daily emtricitabine: 200 mg once daily Truvada: 1 tablet daily
Expanded	Basic regimen + lopinavir/ritonavir (Kaletra) Kaletra: 400/100 = 2 tablets b.i.d.

b.i.d., Twice a day.

HIV PREVENTION BREAKTHROUGHS

A series of HIV prevention breakthroughs cited as significant by researchers include the following: (1) Earlier initiation of ART leads to a 96% reduction in HIV transmission to uninfected partners—those who took the medication Truvada as prescribed could significantly decrease their risk of becoming infected; (2) Increased HIV testing and increased number of infected patients receiving ART help individual patients and the community by decreasing the community viral load; and (3) Medical male circumcision reduces the risk of female-to-male sexual transmission of HIV by approximately 60%, an important intervention in developing countries with limited treatment and prevention options.

CRITICAL THINKING CASE STUDY

JP is a 35-year-old patient who was recently diagnosed with HIV. Other than a recent "case of the flu" approximately 1 month ago, she has been healthy. She has been divorced for 2 years and has a 3-year-old child. JP tested HIV negative in the first trimester of her pregnancy and was not retested during the third trimester. She reports that the relationship with her husband was monogamous and that they did not use condoms. JP began a relationship with a new partner 1 year ago. He claimed to be HIV negative, and they did not use condoms (JP takes oral contraceptives for pregnancy prevention). JP denies a history of intravenous drug use and other high-risk behaviors. Her baseline labs include a CD4 of 450/20% and a viral load of 75,000 copies/mm^3. Her genotypic resistance assay shows no baseline resistance. Her preference is for a once-a-day regimen. She may want to have another child but is not certain.

1. JP asks the nurse when she may have become infected with HIV. What are some of the responses that the nurse should include in a discussion with the patient?
2. Considering JP's preference for a daily antiretroviral regimen, and in view of her history, which medication regimens could be considered for this patient? What, if any, risk-benefit discussion should occur with regard to choices?
3. JP begins ART. She takes the medication without missing any doses for 4 weeks. Her follow-up laboratory results show a CD4 count of 500/22% cells/mL and a viral load of 400 copies/mL. She schedules a follow-up appointment for 2 months later, with laboratory testing preceding her appointment. She calls after 2 weeks, complaining of a painful rash on her back. JP is diagnosed with herpes zoster. She is discouraged and thinks her HIV is worsening. What explanation can the nurse give for the occurrence of this new diagnosis?
4. At her next routine visit, JP says that she missed two doses of her medications because she had an unplanned overnight stay during a trip. What counseling and interventions should the nurse include in her discussion with the patient?

NCLEX STUDY QUESTIONS

1. During routine prenatal testing, a patient is diagnosed with HIV infection. To help prevent perinatal transmission of HIV to the fetus, what is the nurse's best action?
   - a. Provide the patient with contact information for an AIDS support group.
   - b. Educate the patient about the risks of HIV disease to the fetus.
   - c. Notify the CDC of the patient's diagnosis.
   - d. Provide written and oral education about the use of ART during pregnancy.
2. When a patient does not appear for a routine clinic visit, the nurse calls to ask about the missed visit. The patient says, "I don't need to come any longer. I'm so glad I no longer have HIV." The nurse learns that recent laboratory results indicated an "undetectable" HIV viral load and that the patient stopped his medication several weeks earlier. What is the nurse's best response?
   - a. Inform the patient that he must be seen immediately because the undetectable viral load indicates that his medication stopped working.
   - b. Have the patient reschedule his clinic visit.
   - c. Congratulate the patient on his treatment success.
   - d. Educate the patient about the continued need for his medications and ongoing laboratory monitoring.
3. The nurse advises HIV-positive patients about blood draws for CD4 count. What is the correct information to give them about when and how this laboratory blood work should be done?
   - a. At the same laboratory at approximately the same time of day whenever possible
   - b. After a 10-hour fast
   - c. Approximately 1 hour after taking antiretroviral medications
   - d. At any laboratory at any time of day
4. In collaboration with the patient on ART, the nurse formulates a plan of care. Which items are appropriate to include in planning? (Select all that apply.)
   - a. Patient's viral load will become and remain undetectable.
   - b. Patient will not experience secondary infection.
   - c. Patient will promptly report new onset of symptoms and side effects.
   - d. Patient's laboratory blood work will be within normal limits.
   - e. Patient will adhere to medication regimen and/or report difficulties related to adherence.
5. A patient is to start on efavirenz (Sustiva). Which points are important for the nurse to include in health teaching for this patient? (Select all that apply.)
   - a. Dose is given at bedtime to minimize CNS adverse effects.
   - b. Avoid alcohol because of adverse effects to the liver.
   - c. Dose is given after breakfast to minimize CNS adverse effects.
   - d. High-fat meals will decrease absorption of medication.
   - e. Hyperglycemia, jaundice, and diabetes mellitus are side effects.

OBJECTIVES

- Compare and contrast active and passive immunity.
- Compare and contrast active natural and active acquired immunity.
- Describe infectious diseases for which vaccines are currently available.
- Outline the currently recommended childhood immunization schedule.
- Discuss vaccines routinely administered to adults.
- Discuss contraindications to the administration of recommended immunizations.
- Explain the nursing interventions, including teaching, related to the administration of vaccines.

Timely administration of immunizations protects individuals from illness. Immunizations can also ultimately lead to the eradication of disease, as was the case with smallpox in 1977; therefore, universal immunization is a national goal. The 2009 United States National Immunization Survey estimates that 63.6% of 19- to 35-month-old children have received the recommended number of doses of DTaP, polio, hepatitis B, *Haemophilus influenzae* type B, pneumococcal, MMR, and varicella vaccines. This is down from 68.4% in 2008. Among this cohort of children, 0.6% received no immunizations at all.

Findings from the survey also found that vaccine coverage differed by ethnicity and by economic status. In general, white children had higher vaccination rates than nonwhite children. Also, poverty increased the likelihood that a child would not be fully vaccinated.

ACTIVE IMMUNITY

Active immunity occurs as a part of the human immune response, which is activated when a **pathogen** such as a bacterium or virus invades the body. The body recognizes this pathogen as a foreign substance and promptly begins producing **antibodies** (also called *immunoglobulins*) and other infection-fighting cells whose responsibility it is to rid the body of this foreign substance. On first exposure to the pathogen, the immune response is relatively slow and is typically accompanied by signs and symptoms of disease. However, the immune system retains memory of this pathogen. If this same pathogen invades the body again, the immune response, including the increased production of pathogen-specific antibodies, occurs much more rapidly and generally prevents disease. This active **natural immunity** may be present for the remaining life of the individual. Natural immunity is genetically determined in specific populations or families. Some pathogens cannot infect certain species because the environment is not suitable (e.g., measles cannot reproduce in dogs; thus, dogs have a natural immunity to measles).

Acquired immunity occurs from exposure to an antigen or from passive injection of immunoglobulins. Active protection against disease may also be provoked by immunization. **Vaccination** involves the administration of a small amount of **antigen**, which although capable of stimulating an immune response does not typically produce disease. The antigen in vaccines may be produced in several ways. Traditional vaccines contain the whole or components of an inactivated (killed) microorganism. Other vaccines are **attenuated viruses** composed of live, attenuated (weakened) microorganisms. **Toxoids** are inactivated toxins, the harmful disease-causing substance produced by some microorganisms.

Some newer vaccines are called **conjugate vaccines**. Such vaccines require a protein or toxoid from an unrelated organism to link to the outer coat of the disease-causing microorganism. This linkage creates a substance that can be recognized by the immature immune system of young infants. *Haemophilus influenzae* type B is an example of a conjugate vaccine.

Recombinant subunit vaccines involve the insertion of some of the genetic material (e.g., deoxyribonucleic acid [DNA]) of a pathogen into another cell or organism, where the antigen is then produced in massive quantities. These antigens are then used as a vaccine in place of the whole pathogen. Hepatitis B is an example of this type of vaccine.

An **adjuvant**, often an aluminum salt such as aluminum hydroxide, aluminum phosphate, or aluminum potassium sulfate, is a substance sometimes used in the production of a vaccine to increase the vaccine's immunogenicity and to prolong the immune response. Adjuvants may also be added to a vaccine to reduce the amount of antigen needed to produce a dose of vaccine. Adjuvants have been used in the production of immunizations since the 1930s and are found in many U.S. childhood vaccines.

Regardless of the composition of the vaccine, each vaccine is designed to stimulate an immune response against a specific pathogen. Booster doses are sometimes required to maintain sufficient immunity. Because the immune system retains memory, a vaccinated individual who is later exposed to the actual pathogen mounts a rapid immune response, thus preventing disease. This active artificially acquired immunity is the focus of this chapter.

PASSIVE IMMUNITY

Passive immunity occurs when an individual receives antibodies against a particular pathogen from another source. Newborn infants naturally receive passive immunity via the transfer of maternal antibodies across the placenta. Passive immunity may also be acquired through the administration of antibodies pooled from several human or animal sources that have been exposed to disease-causing pathogens. Alternatively, antibodies may be produced using recombinant DNA technology.

Whether natural or acquired, passive immunity is transient, lasting no more than several weeks to a few months. The recipient does not mount his or her own immune response. However, passive immunity is important. It helps young infants who, because of their immature immune systems, are poorly equipped to protect themselves against disease. Acquired passive immunity is important when (1) time does not permit active vaccination alone, (2) the exposed individual is at high risk for complications of the disease, or (3) the individual suffers from an immune system deficiency that renders that person unable to produce an effective immune response.

VACCINE-PREVENTABLE DISEASES

In the United States, more than 20 infectious diseases may be prevented by active vaccination. Many of these vaccines are routinely administered to healthy children and adults. Others are reserved for special populations, such as military personnel, travelers to certain foreign countries, or the chronically ill. Table 36-1 provides an overview of the disease manifestations and vaccine information, including route of administration and storage temperature. Vaccine-preventable diseases include, but are not limited to, anthrax, diphtheria, *Haemophilus influenzae* type B (Hib), hepatitis A, hepatitis B, human papillomavirus, influenza, Japanese encephalitis, measles, meningococcal disease, mumps, pertussis, pneumococcal disease, poliomyelitis, rabies, rotavirus, rubella, smallpox, tetanus, tuberculosis, typhoid, varicella, yellow fever, and herpes zoster.

TABLE 36-1 VACCINE-PREVENTABLE DISEASES

DISEASE, ROUTE OF ADMINISTRATION, AND STORAGE TEMPERATURE	MANIFESTATIONS	VACCINE
Anthrax/subQ	Spectrum involves three types of infection: Cutaneous (malignant pustule): a painless sore that develops at the site of a cut Inhalational (wool sorter's disease): severe dyspnea, cyanosis, fever, and death Gastrointestinal: abdominal pain, vomiting, bloody diarrhea, toxemia, shock, possibly death Inhalational form associated with use of bacteria in biologic warfare	Inactivated bacteria Administration limited to military personnel
Diphtheria/IM 35°-46° F (2°-8° C)	Respiratory infection May result in heart failure or paralysis if left untreated	Toxoid Contained in DTaP, Tdap, DT, Td, DTaP-Hib, DTaP-IPV, DTaP-IPV/Hib, and DTaP-IPV-hepatitis B vaccines
Haemophilus influenzae type B (Hib)/IM 35°-46° F (2°-8° C)	Causes meningitis, pneumonia, sepsis, arthritis, and skin and throat infections Most serious in children younger than 1 y	Bacterial conjugate Contained in Hib, DTaP-Hib, Hib-hepatitis B, DTaP-IPV/Hib, and Hib-MCV vaccines
Hepatitis A/IM 35°-46° F (2°-8° C)	Fever, malaise, jaundice, anorexia, and nausea Acute, self-limited illness	Inactivated viral antigen Contained in hepatitis A and hepatitis A–hepatitis B vaccines Administered to children 12-23 mo, high-risk populations, and persons traveling to certain foreign countries
Hepatitis B/IM 35°-46° F (2°-8° C)	Malaise, anorexia, arthralgias, arthritis, jaundice Chronic infection can occur, leading to liver cirrhosis, liver cancer, and death	Recombinant viral antigen Contained in hepatitis B, Hib-hepatitis B, DTaP-IPV–hepatitis B, and hepatitis A–hepatitis B vaccines
Human papillomavirus/IM 35°-46° F (2°-8° C)	Cervical, anal, and oropharyngeal cancers; genital warts	Recombinant viral antigen Administered to women 9-26 y One vaccine is also licensed for use in men 9-26 y
Influenza/IM, intradermal, intranasal *Inactivated:* 35°-46° F (2°-8° C) *Live attenuated:* ≤5° F (–15° C)	Fever, chills, headaches, malaise, myalgias, nasal congestion, and cough Occasionally causes croup and pneumonia	Inactivated viral components (IM and intradermal) or live attenuated virus (intranasal)
Japanese encephalitis/subQ 35°-46° F (2°-8° C)	Headache, fever, myalgias, encephalitis	Inactivated virus Administered to some foreign travelers
Measles/subQ 35°-46° F (2°-8° C), but may be frozen	Rash, fever, cough, nasal congestion, conjunctivitis, pneumonia Occasionally results in encephalitis	Live virus Contained in measles, MMR, and MMR-varicella vaccines
Meningococcal disease/subQ, IM 35°-46° F (2°-8° C)	Fever, sepsis, rash, meningitis	MPSV4: portions of inactivated bacterial capsule (subQ) MCV4*:* bacterial conjugate (IM), expected to give better, longer-lasting protection Contained in MCV4, MPSV4, and Hib-MCV vaccines
Mumps/subQ 35°-46° F (2°-8° C), but may be frozen	Swelling of salivary glands, fever, and headache Rarely causes encephalitis, inflamed testicles, and permanent hearing loss	Live attenuated virus Contained in mumps, MMR, and MMR-varicella vaccines
Pertussis ("whooping cough")/IM 35°-46° F (2°-8° C)	Severe coughing spasms Rarely causes pneumonia, seizures, encephalitis, and death Symptoms more severe in infants and young children	Antigenic components of inactivated bacteria (acellular) Contained in DTaP, Tdap, DTaP-Hib, DTaP-IPV–hepatitis B, and DTaP-IPV/Hib vaccines
Pneumococcal disease/IM, subQ 35°-46° F (2°-8° C)	Ear infections, sinus infections, pneumonia Occasionally causes sepsis and meningitis	Polysaccharide vaccine (PPV23) contains portions of 23 serotypes of pneumococcal bacterial capsules (subQ); administered to older adults and certain other high-risk populations ≥2 y Protein conjugate vaccine (PCV13) contains portions of 13 serotypes of pneumococcal bacterial capsules (IM); recommended for routine administration to children <2 y and certain older high-risk children

Continued

TABLE 36-1 VACCINE-PREVENTABLE DISEASES—cont'd

DISEASE, ROUTE OF ADMINISTRATION, AND STORAGE TEMPERATURE	MANIFESTATIONS	VACCINE
Poliomyelitis/subQ, IM 35°-46° F (2°-8° C)	Mild form causes fever, sore throat, nausea, and headaches Severe form causes paralysis and death	Inactivated virus Contained in IPV, DTaP-IPV, DTaP-IPV–hepatitis B, and DTaP-IPV/Hib vaccines
Rabies/IM 35°-46° F (2°-8° C)	Anxiety, difficulty swallowing, seizures; almost always progresses to death	Inactivated virus Administered to high-risk groups (e.g., veterinarians, animal handlers) and persons traveling to areas where rabies is common
Rotavirus/PO 35°-46° F (2°-8° C)	Vomiting and diarrhea; may be particularly severe in infants/young children	Live attenuated virus
Rubella ("German measles")/subQ 35°-46° F (2°-8° C), but may be frozen	Rash, fever Birth defects if acquired by pregnant patients	Live attenuated virus Contained in rubella, MMR, and MMR-varicella vaccines
Smallpox/skin prick 35°-46° F (2°-8° C)	High fever, severe headache, backache, abdominal pain, and lethargy lasting 2-5 days Then extensive rash that begins as macules and progresses to papules, then firm vesicles, and, finally, deep-seated, hard pustules that cause significant scarring Natural disease eradicated worldwide in 1980 May be used as a weapon of bioterrorism	Live virus Limited immunization program to include military personnel, civilian health care workers, and emergency personnel began in 2002
Tetanus ("lockjaw")/IM 35°-46° F (2°-8° C)	Headache, irritability, muscle spasms (jaw, neck, arms, legs, back, and abdomen)	Toxoid Contained in tetanus, DTaP, DTaP-Hib, DTaP-IPV, DT, DTaP-IPV–hepatitis B, DTaP-IPV/Hib, Tdap, and Td vaccines
Tuberculosis ("TB")/ID (preferred), subQ 35°-46° F (2°-8° C)	Highly contagious respiratory infection May also cause meningitis and bone, joint, and skin infections	Live attenuated bacteria Referred to as BCG vaccine Not routinely administered in the United States Prevents severe disease, but does not prevent infection with the bacterium
Typhoid/subQ, PO 35°-46° F (2°-8° C)	Fever, headache, anorexia, abdominal pain, enlarged liver and spleen, constipation, and later, diarrhea	Available as live attenuated bacteria (PO), or inactivated components of typhoid bacterial capsule (subQ) Recommended only for travelers to certain foreign countries
Varicella ("chickenpox")/subQ ≤5° F (–15° C)	Fever and rash, consisting of a few to hundreds of itchy, blisterlike lesions Symptoms more severe in older children and adults Complications may include encephalitis, bacterial skin infections, pneumonia, Reye's syndrome, and death	Live attenuated virus Contained in varicella and MMR-varicella vaccines
Yellow fever/subQ 35°-46° F (2°-8° C)	Fever, jaundice, and gastrointestinal hemorrhage	Live attenuated virus Recommended for travelers to foreign countries with high yellow fever rates Required by international regulations for travel to and from certain countries
Zoster ("shingles")/subQ ≤5° F (–15° C)	Painful, blisterlike rash in a dermatomal distribution Occurs due to reactivation of varicella virus Following resolution of rash, may have prolonged severe pain (postherpetic neuralgia)	Live attenuated virus Administered to persons ≥60 y

BCG, Bacille Calmette-Guérin; *DT,* diphtheria-tetanus; *DTaP,* diphtheria-tetanus–acellular pertussis; *Hib, Haemophilus influenzae* type B; *ID,* intradermal; *IM,* intramuscular; *IPV,* inactivated poliovirus; *MMR,* measles-mumps-rubella; *mo,* months, *PO,* by mouth; *subQ,* subcutaneous; *Td,* tetanus-diphtheria; *y,* year; >, greater than; ≥, greater than or equal to; <, less than, ≤, less than or equal to.

CHILDHOOD IMMUNIZATIONS

For the most current information on childhood immunizations, consult the Centers for Disease Control and Prevention (CDC) website at *www.cdc.gov/vaccines*. A summary of rules for childhood immunizations, updated in 2013, is also located at the Immunization Action Coalition's website at *www.immunize.org/catg.d/p2010.pdf*. Information about each vaccine includes route of administration, schedule for routine vaccine administration, minimum dosing intervals, and contraindications to use. Recommended vaccines are diphtheria-tetanus-acellular pertussis, inactivated polio, varicella, measles-mumps-rubella, *Haemophilus influenzae* type B, hepatitis A, hepatitis B, pneumococcal conjugate, influenza, meningococcal conjugate, human papillomavirus, and rotavirus. Before immunizations are administered, children and their caregivers should be questioned regarding use of prescription and over-the-counter medications, including herbal preparations, and any food or drug allergies (Herbal Alert 36-1).

HERBAL ALERT 36-1

Vaccines

Although patients should always be asked about their use of prescription and over-the-counter drugs, there are no known interactions between vaccinations and herbal preparations.

ADULT IMMUNIZATIONS

While much emphasis is placed on regularly immunizing infants and children, adult immunizations are frequently overlooked. However, immunizations are equally important to the health and well-being of adults. Routine vaccines for adults may include tetanus-diphtheria-acellular pertussis, tetanus-diphtheria, influenza, pneumococcal polysaccharide, human papillomavirus, measles-mumps-rubella, varicella, and zoster. In certain situations, adults may also be immunized with some or all of the following vaccines: hepatitis A, hepatitis B, pneumococcal polysaccharide, and meningococcal polysaccharide. The most current recommendations for adult immunization can be found at *www.cdc.gov/vaccines*, and the Immunization Action Coalition's website contains a summary of rules for adult immunization (*www.immunize.org/catg.d./p2011.pdf*). The CDC suggests review of adult immunization records on decade birthdays—ages 30, 40, and 50 years, and so on.

A strategy called **cocooning** focuses on immunizing adults in close contact with newborns and young infants to protect the babies from contracting vaccine-preventable diseases in the months before they are eligible to receive the vaccine themselves. Currently, these efforts focus on preventing pertussis in newborns and young infants by administering Tdap vaccine to parents, grandparents, and other caregivers.

SAFETY: Preventing Medication Errors

Do not confuse …

- Hepatitis A vaccines in different doses for child/adolescent and adult
- Hepatitis B vaccines in different doses for child/adolescent and adult
- Hepatitis B vaccines and hepatitis B immunoglobulin
- DTaP and Tdap vaccines, which contain different amounts of individual vaccine components and are indicated for different age groups
- Zostavax, a vaccine administered to adults to prevent shingles, and Varivax, which prevents chickenpox and is approved for use in susceptible children and adults (both are preparations of varicella virus vaccine)

IMMUNIZATION BEFORE INTERNATIONAL TRAVEL

International travel warrants the administration of all routine vaccines indicated based on age or immunization history. It may also require consideration of additional vaccines, depending on the travel destination.

Travelers may need to consider vaccination against typhoid and yellow fever. Typhoid is caused by a bacterium, *Salmonella enterica* typhi, which is generally spread via contaminated food and water (see Table 36-1). Risk of contracting this infection is greatest for travelers to India, Pakistan, Mexico, Bangladesh, the Philippines, and Haiti. Even stays of less than 2 weeks pose significant risk. Two vaccines are available for use in the United States: The live oral vaccine can be administered to persons 6 years of age and older and consists of four capsules, one taken every 48 hours, with the series completed 1 week before potential exposure. A booster consisting of the same four-capsule regimen is recommended every 5 years. The polysaccharide vaccine may be administered to travelers 2 years of age and older. It is administered at least 2 weeks before expected exposure as a single, intramuscular (IM) injection. A booster dose is recommended every 2 years.

Yellow fever is a mosquito-borne viral illness. The disease occurs only in sub-Saharan Africa and tropical South America. The vaccine is administered as a single injection; a booster every 10 years is recommended. In the United States, the vaccine is administered only at authorized vaccine centers throughout the country.

Other vaccines needed for travel may include meningococcal, rabies, and Japanese encephalitis vaccines. Current vaccine recommendations and related travel information are available from the CDC at 1-800-CDC-INFO or *www.cdc.gov/travel*.

REPORTING OF DISEASES AND ADVERSE REACTIONS

Health care providers are responsible for reporting cases of vaccine-preventable diseases to public health officials, who make weekly reports to the CDC. These data identify whether an outbreak is occurring and the impact of immunization policies and procedures.

Vaccines are generally safe. Common mild reactions include swelling at the injection site and fever. Awareness of the contraindications for use of vaccines decreases the incidence of serious adverse reactions. Absolute contraindications include moderate or severe illness or **anaphylaxis** (a serious, potentially life-threatening allergic reaction) to a specific vaccine or vaccine component. It is important to review vaccine-specific contraindications prior to administering any vaccine. However, in general, vaccines may be given in cases of mild acute illness or convalescent phase of illness; antimicrobial therapy; exposure to infectious disease; or premature birth.

Health care providers must report adverse reactions to the Vaccine Adverse Events Reporting System. Information and forms are available at *http://vaers.hhs.gov/index*. The National Childhood Vaccine Injury Act of 1986 set forth the National Vaccine Injury Compensation Program (NVICP). This program provides compensation for injury or death caused by a vaccination. The NVICP does not require proof of negligence on the part of a health care provider. For more information, visit *www.hrsa.gov/vaccinecompensation/*.

VARICELLA VACCINE

Prototype Drug Chart 36-1 provides the pharmacologic data for varicella vaccine.

Pharmacokinetics Biologic products such as vaccines do not undergo the pharmacokinetic processes associated with other drug therapy.

Pharmacodynamics **Seroconversion** is the acquisition of detectable levels of antibodies in the bloodstream. In the case of varicella vaccine, seroconversion occurs in more than 98% of 12-month-old to 12-year-old recipients approximately 6 weeks after receiving a single dose of vaccine. Susceptible persons 13 years of age and older who receive two doses of varicella vaccine 4 to 8 weeks apart show a seroconversion rate of approximately 75% 4 weeks after the first dose and 99% 4 weeks after the second dose. Despite the high rate of initial seroconversion among children 12 months to 12 years of age, clinical trials have shown that over a 10-year period the vaccine's effectiveness in preventing disease was 94% for children receiving one dose of vaccine and 98% for those who received two doses. Therefore, beginning in 2007, a second dose of varicella vaccine was recommended for all susceptible individuals, including children.

Contraindications

Varicella vaccine should be avoided in patients with a history of previous anaphylaxis to this vaccine or to any of its

PROTOTYPE DRUG CHART 36-1

Varicella

Drug Class Vaccine Trade Name: Varivax Pregnancy Category: C	**Dosage** 0.5 mL subQ × 2 doses. First dose: 12-15 mo; second dose: 4-6 y; catch-up initiated any time after 12-15 mo <13 y: space doses at least 3 mo apart ≥13 y: space doses 4-8 wk apart **For varicella prophylaxis for outbreak control of local epidemics of wild-type varicella virus in susceptible persons following varicella exposure,** consult the current recommendations of the CDC
Contraindications Previous anaphylaxis to this vaccine or to any of its components; pregnancy or possibility of pregnancy within 1 mo; immunocompromised vaccine recipient; presence of moderate to severe acute illness; active untreated tuberculosis	**Drug-Lab-Food Interactions** Drug: Separate from other live virus vaccines (e.g., MMR, intranasal flu) by 4 wk if not given on same day; delay VV for up to 11 mo after blood transfusion or Ig; delay Ig for 2 mo after VV; high-dose immunosuppressant medications; avoid with salicylates for 6 wk after VV
Pharmacokinetics Not applicable	**Pharmacodynamics** Seroconversion rates: 12 mo–12 y: >98% at 4-6 wk after vaccination ≥13 y: ~75% 4 wk after first dose, and 99% 4 wk after second dose
Therapeutic Effects/Uses Prevention of chickenpox. When administered to susceptible individuals, vaccine results in complete protection from chickenpox for the majority. For the minority in whom breakthrough chickenpox develops after vaccination, the disease is typically very mild. The vaccine may also provide prophylaxis protection if administered within 3-5 d of exposure to chickenpox. Mode of Action: Stimulates active immunity against natural disease	
Side Effects Pain and redness at injection site, fever, chickenpox-like rash (generalized or confined to area surrounding injection site)	**Adverse Reactions** Anaphylaxis, thrombocytopenia, encephalitis, Stevens-Johnson syndrome

d, Day; *Ig,* immune globulin; *MMR,* measles-mumps-rubella; *mo,* month; *subQ,* subcutaneous; *VV,* varicella vaccine; *wk,* week; *y,* year; *<,* less than; *≥,* greater than or equal to.

components, including gelatin and neomycin. It is also contraindicated in the presence of moderate to severe acute illness or active untreated tuberculosis.

While varicella infection can cause fetal harm, the possible effects of the vaccine on fetal development are currently unknown. Therefore, varicella vaccine is contraindicated during pregnancy. Pregnancy should also be avoided for at least 1 month after each dose of the vaccine. *Note:* This recommendation differs from the product package insert, which suggests a 3-month delay in pregnancy.

Patients who are immunocompromised because of malignancies, high-dose systemic steroids, or other immunosuppressive therapy should avoid varicella vaccine. Likewise, the vaccine is generally contraindicated in the presence of primary or acquired immunodeficiencies. However, vaccination may be considered in children with certain classes of human immunodeficiency virus (HIV) infection.

Drug Interactions

Frequently a patient is eligible for several immunizations at any given visit. A patient receiving varicella vaccine may receive all other vaccines concurrently as long as each is administered at a separate site. If the MMR or other live virus vaccine is not given the same day as the varicella vaccine, administration of the two vaccines should be separated by at least 4 weeks.

If a patient has received a transfusion of blood or blood products, including immune globulin, administration of the varicella vaccine will need to be deferred for as long as 11 months. Likewise, such blood products should be avoided for at least 2 months after vaccination if possible. Blood products and immune globulin interfere with the body's production of antibodies specific to chickenpox, thereby decreasing the likelihood that active immunity will develop.

Reye's syndrome has occasionally occurred in children following natural chickenpox infection. The majority of these children were also receiving salicylate medications (e.g., aspirin). Therefore, it is generally recommended that patients avoid salicylates for 6 weeks after vaccination.

NEWER DEVELOPMENTS AND THE FUTURE OF VACCINES

A small outbreak of anthrax cases in the United States in 2001 increased the level of awareness of the anthrax vaccine. As a biologic weapon, anthrax is highly lethal. It is easily produced, stored, and spread over large areas. Proper vaccination is an essential part of protection against this disease. Approved by the FDA in 1970, anthrax vaccine has been routinely and safely administered to laboratory and military personnel, livestock farmers, and veterinarians. The vaccine requires six injections: three given 2 weeks apart followed by three additional doses at 6, 12, and 18 months. No serious side effects have been reported, but the vaccination is contraindicated during pregnancy. Strides have been made in the development of an oral anthrax vaccine. The vaccine is derived from a genetically modified plant virus. The virus is introduced into a plant, where it then stimulates the plant to produce new proteins. These proteins are extracted and used to produce a vaccine. When the vaccine is administered to a human, the person's body reacts as if infected with anthrax and creates antibodies against the bacterium. In the event of a bioterrorism attack, large numbers of individuals can be rapidly immunized with an oral vaccine. Additional information is available at *www.anthrax.osd.mil*.

Smallpox was eradicated worldwide by 1980. The United States discontinued routine childhood immunization against smallpox in 1971. However, since the events of September 2001, concern has arisen that the smallpox (or variola) virus could be used as a bioterrorist weapon. Unlike anthrax, smallpox virus is not airborne and is transmitted through human bodily fluids or contaminated materials. A smallpox immunization plan has been implemented in the United States *(www.bt.cdc.gov/agent/smallpox/vaccination/)*. However, there has been some resistance to vaccination because of a lack of perceived threat and because of the risk of significant side effects from the vaccine. The currently available vaccine is a live virus preparation. It is administered using a bifurcated needle to deliver the vaccine into the epidermis. A skin reaction occurs at the immunization site 3 to 5 days later and eventually leaves a scar. Boosters may be recommended every 10 years.

It has long been known that immunity to pertussis, or "whooping cough," wanes over time and that adolescents and adults are often responsible for transmitting this infection to vulnerable, incompletely immunized infants and young children. While a relatively benign illness in the older population, pertussis in infants is associated with significant morbidity and mortality. Two products containing tetanus and diphtheria toxoids along with acellular pertussis are licensed for use in older children and adults. Adacel is approved for use in people 11 to 64 years of age, and Boostrix is approved for use in people 10 years of age and older. Each vaccine contains the same antigens as its respective counterpart administered to young children (DTaP), but with reduced quantities of diphtheria and acellular pertussis (Tdap). It is recommended that for booster immunization, adolescents and adults receive a one-time dose of Tdap in lieu of Td vaccine.

Herpes zoster, commonly known as "shingles" or *zoster*, occurs as the result of reactivation of the varicella virus. Following a primary varicella infection ("chickenpox"), the virus persists but becomes dormant in the body, usually settling in a dorsal root ganglion. Zoster often occurs decades after the primary varicella infection. It appears that development of zoster may be related to a decline in immunity to the varicella-zoster virus (VZV). Zoster is characterized by a painful rash that presents in a dermatomal distribution. Especially in older adults, resolution of the rash may be followed by a chronic, severe, sometimes debilitating pain, referred to as *postherpetic neuralgia*. A live attenuated vaccine, Zostavax, is licensed for use as a one-time injection in adults 50 years of age and older. The vaccine has been shown to boost VZV immunity among vaccine recipients. In clinical trials, Zostavax prevented zoster in about 50% of people who received the vaccine. Effectiveness appears to decrease with increasing age of the vaccine recipient. In those who received the vaccine yet went on to develop zoster, the duration of pain was reduced.

Rotavirus is a leading cause of severe acute gastroenteritis in infants and young children. RotaTeq, a live oral vaccine containing five strains of rotavirus, is effective in protecting against severe gastroenteritis and significantly reduces the need for hospitalization among infected children. The vaccine is administered at 2, 4, and 6 months of age. A second rotavirus vaccine, Rotarix, consists of two doses administered orally at 2 and 4 months of age.

Gardasil, the human papillomavirus (HPV) vaccine, has been called the first vaccine designed to prevent cancer. It contains four strains of human papillomavirus, which account for the vast majority of cases of cervical cancer and genital warts. HPV is also associated with several less common cancers, such as vaginal and vulvar cancers in women and anal and oropharyngeal cancers in both men and women. A recombinant vaccine, it is licensed for routine use in 9- to 26-year-old female patients and is administered as a three-shot series. The manufacturer of Gardasil has received FDA approval for use of its vaccine in male patients 9 to 26 years of age. The FDA turned down Merck's request for expanded use in women 27 to 45 years of age. A second HPV vaccine, Cervarix, is FDA approved for use in women. Because HPV is sexually transmitted, the vaccine is most effective if administered before initiation of sexual intercourse. (See Chapter 58 for more information about sexually transmitted infections and this vaccine.)

The first pneumococcal conjugate vaccine, Prevnar, provides protection against seven serotypes of pneumococci. Since its introduction, the incidence of invasive disease caused by these seven strains has dramatically decreased. However, the incidence of disease caused by nonvaccine serotypes is on the rise. One such serotype, 19A, now accounts for 42% of pneumococcal disease. In early 2010, a conjugate vaccine containing 13 serotypes, including 19A, gained FDA approval. It replaces the seven-valent vaccine.

While each vaccine as a single antigen has been available for many years, in June 2012 the FDA approved Menhibrix, a combination vaccine for infants and children 6 weeks to 18 months of age, for prevention of invasive disease cause by *Neisseria meningitides* and *Haemophilus influenza* type b. Menhibrix is given as a four-dose series at 2, 4, 6, and 12 to 15 months of age, although the first dose may be given as early as 6 weeks of age, and the fourth dose may be administered as late as 18 months of age. However, the United States Advisory Committee on Immunization Practice has not recommended routine immunization of infants against meningococcal disease, so the utility of this vaccine is currently unclear.

New delivery systems for vaccines are in development. Timed-release pills in a one-time dose have the potential to offer lifetime immunity to a targeted disease, eliminating the need for booster vaccination. In addition, skin patches may one day be used to administer tetanus and influenza vaccines.

Nursing Process

Patient-Centered Collaborative Care

Vaccines

Assessment

- Identify barriers to timely and complete immunization (e.g., belief that vaccine-preventable diseases no longer exist, misunderstanding of true contraindications to immunization, concerns regarding vaccine safety and efficacy, fear of multiple injections, cost).
- Obtain medical history, including history of malignancy or other immune deficiency.
- Determine history of pregnancy or possible pregnancy within the next month. Many vaccines are contraindicated during pregnancy.
- Obtain drug history, including high-dose immunosuppressants, blood transfusions, and immune globulin.
- Obtain a list of herbal products used by patient and mother (in case of breastfed infant).
- Determine complete allergy history, including drugs, vaccines, food, and environmental allergies.
- Assess for adverse reactions (other than allergic) to previous doses of vaccine or any vaccine component.
- Assess for symptoms of moderate to severe acute illness with or without fever.
- Screen for unvaccinated or immunocompromised household contacts at every visit.
- Obtain immunization history and history of vaccine-preventable diseases to determine current vaccine needs. For example, a person with a reliable history of chickenpox or herpes zoster ("shingles") does not need varicella vaccine; natural immunity is assumed.

Nursing Diagnoses

- Deficient knowledge related to vaccine-preventable diseases and risks and benefits of vaccination
- Risk for ineffective health maintenance related to nonadherence to recommended immunization schedule
- Risk for injury related to adverse reactions to immunizations
- Readiness for enhanced immunization status related to expressed desire to improve knowledge about vaccines

Planning

- Patient or patient's parent or guardian will possess knowledge of vaccine-preventable diseases and risks and benefits of vaccination.
- Patient or patient's parent or guardian will adhere to recommended immunization schedule for vaccine-preventable diseases unless contraindications exist.
- Patient will be free of adverse reactions.

Nursing Interventions

- Strictly adhere to individual vaccine storage requirements to ensure potency of the product.
- Upon preparation, including reconstitution of a given vaccine, administer within time limits stated in package insert to ensure potency.
- Administer at separate sites all vaccines for which patient is eligible at the time of the visit. *Do not mix vaccines in the same syringe.*
- Document in patient's record the vaccination date, route, and site of administration; vaccine type, manufacturer, lot number, and expiration date; and name, business address, and title of person administering vaccine.
- Observe patient for signs and symptoms of adverse reactions to vaccines.
- Keep epinephrine readily available for immediate use in case of anaphylactic reaction.
- Provide patient with a record of immunizations administered.

Patient Teaching

General

- Discuss vaccine-preventable diseases with patient and/or patient's family, including manifestations and risk of contracting.
- Answer all questions regarding vaccine safety and efficacy.
- Advise female patients of childbearing age to avoid pregnancy for 1 month, depending on the vaccines administered.
- Advise patients to avoid contact with immunocompromised persons, depending on vaccines to be administered.
- Provide patient or patient's family with current Vaccine Information Statements (VISs), available from the CDC, for each vaccine before its administration, as required by federal law.
- Remind patient or patient's family to bring immunization record to all visits.
- Provide patient or patient's family with return date for next vaccination(s) based on assessment of immunization history.

Side Effects

- Discuss common side effects of vaccines, such as injection site soreness, fever, and side effects specific to individual vaccines.
- Offer suggestions for management of common side effects (e.g., cold compresses for injection site soreness, acetaminophen for soreness or fever).
- Advise patient or patient's family to contact the health care provider if signs of a serious reaction are noted.

Cultural Considerations

- Modify communications to meet cultural needs of patient and family.
- Use a professional interpreter when necessary.
- Provide patient and family with VISs in preferred language (available at *www.immunize.org*.)

Evaluation

- Evaluate patient's or family's understanding of rationale for immunizations.
- Evaluate patient adherence to recommended immunization schedule.
- Evaluate if patient is free from adverse reactions.

KEY WEBSITES

CDC's National Immunization Program: *www.cdc.gov/vaccines*
CDC's Travel Health: *wwwnc.cdc.gov/travel*
Immunization Action Coalition: *www.immunize.org*
Vaccine Education Center at Children's Hospital of Philadelphia: *www.chop.edu/service/vaccine-education-center/home.html*

CRITICAL THINKING CASE STUDY

JW, 29 years of age, presents in late October to the immunization clinic, accompanied by her 2-month-old daughter and her son, who turned 6 years old in September. JW reports that they all need shots.

1. JW will soon be returning to work at a long-term care facility for developmentally disabled adults. She reports that her new employer is encouraging her to be immunized against hepatitis B. She wonders how long it will take her to complete the vaccine series. What is the nurse's best response?
2. The nurse administers JW's first dose of hepatitis B vaccine. When should JW return for the next dose?
3. The nurse asks JW about her vaccine history. JW says she does not have an immunization card but remembers receiving "a booster when I stepped on a nail at my high school graduation picnic." What "booster" did she likely

receive? At what point is another booster due? What vaccine should she receive for her next booster?

4. JW says her daughter needs her "regular shots." The infant received her first hepatitis B vaccine while in the newborn nursery. Against what vaccine-preventable illnesses should the nurse plan to vaccinate this infant today?
5. When would this infant be due for another series of immunizations?
6. JW asks the nurse about the chickenpox vaccine. She would like her daughter to be vaccinated against chickenpox as soon as possible because she does not want her to suffer through chickenpox as her son did. What is the earliest age at which her daughter can receive varicella vaccine?
7. JW says she has heard that "you can get chickenpox from the vaccination shot." How should the nurse respond to this comment?
8. JW has brought her son's immunization card. It shows he received hepatitis B vaccine at birth, at 2 months, and at 9 months of age. He received DTaP, Hib, polio (IPV), pneumococcal (PCV), and rotavirus vaccines at 2 months, 4 months, and 6 months of age. JW is worried that he will need to start his immunizations over because "he's so far behind." How should the nurse respond to her concern?
9. For what vaccines is JW's son due today?

NCLEX STUDY QUESTIONS

1. The father of a 4-month-old infant calls in to the clinic reporting that his child is having a reaction to immunizations. What is the most important piece of information the nurse should elicit?
   a. A list of the immunizations received
   b. Whether the father has given the infant any acetaminophen
   c. The signs/symptoms the infant is experiencing
   d. The sites used to administer the immunizations
2. The nurse is preparing to administer varicella vaccine to a young woman. Which factor has the greatest implication for this young woman's care?
   a. The patient tells the nurse she is "deathly afraid of needles."
   b. The medical record indicates that the patient is allergic to eggs.
   c. The medical history indicates the patient had leukemia as a young child.
   d. The patient appears to be pregnant.
3. A 38-year-old migrant farm worker presents to the clinic with a cut to his arm sustained when he reached into an old metal drum. The patient has sutures placed, and the attending provider orders "Tdap" for him. What is the nurse's most important action in carrying out this order?
   a. The nurse provides the patient with a Vaccine Information Statement about Tdap in the patient's primary language.
   b. The nurse determines the exact date of the patient's last tetanus booster.
   c. The nurse documents that the patient did not experience any side effects immediately following immunization.
   d. The nurse provides the patient with a record of the immunization administered at the visit.
4. The nurse is preparing to administer routine, recommended immunizations to a medically fragile 6-month-old child. What is the most important information to know about this infant?
   a. The infant receives all feedings via a gastrostomy tube.
   b. The infant receives inhaled steroids daily.
   c. The infant received his previous round of immunizations on time.
   d. The infant is not yet able to roll over.
5. A 61-year-old man is to receive zoster vaccine. What is the most important thing for the nurse to discuss with this patient?
   a. That the vaccine has been stored in a freezer maintained at ≤5° F
   b. The patient's medication list and allergies
   c. That an appropriate length of needle will be used to administer the vaccine subcutaneously
   d. The patient's history of shingles
6. An 18-month-old child is accompanied to the clinic by her grandmother, the child's legal guardian. The grandmother reports that the child is due for her fourth DTaP. The nurse determines that the child should not receive DTaP vaccine today for which reason?
   a. The child received varicella vaccine 2 weeks ago.
   b. The grandmother is undergoing chemotherapy for breast cancer.
   c. The third DTaP was administered 4 months ago.
   d. The child has a runny nose today.
7. The nurse is preparing to administer five immunizations to a pediatric patient. It is essential that the nurse first assess what? (Select all that apply.)
   a. Age of the child
   b. Size of the child
   c. Child's ability to understand importance of immunizations
   d. Child's current health status
   e. Ability of caregiver to protect the child from sun exposure for 24 hours
   f. Child's history of reactions to prior doses of vaccines to be administered
8. The nurse, with the help of an interpreter, has just immunized a 35-year-old woman with Tdap and MMR. It is essential that the nurse proceed with which action(s)? (Select all that apply.)
   a. Provide Vaccine Information Statements (VISs) in the patient's preferred language.

b. Document in the patient's record the date; site and route of administration; vaccine type, manufacturer, lot number, and expiration date; and the name, business address, and title of person administering the vaccine.

c. Administer a dose of ibuprofen to prevent postimmunization fever.

d. Instruct the patient to call for any injection site soreness.

e. Instruct the patient on the use of an epinephrine auto injector to administer in the event of an anaphylactic reaction.

f. Counsel the patient regarding the importance of avoiding pregnancy for 1 month.

Answers: 1, c; 2, d; 3, a; 4, a; 5, b; 6, c; 7, a, b, d, f; 8, b, f.

UNIT XII

Antineoplastic Agents

The development of cancer is a multistep process that is influenced by environmental hazards (e.g., chemicals, radiation), genetic predisposition (e.g., genetic mutations), lifestyle factors (e.g., smoking, alcohol use), diet (e.g., high in animal fats), infection (e.g., Epstein-Barr, *Helicobacter pylori*, human papillomavirus [HPV]), and immune suppression (e.g., HIV infection, immunosuppressive medications). Cancer (malignant, neoplastic) cells are characterized by unregulated growth, lack of differentiation, and spread (metastasis) to other places in the body.

CELL CYCLE

All cells progress through a distinct cycle that consists of four phases directed toward cell replication and a fifth resting stage. In this way, the cell cycles of normal and cancer cells are similar. The first phase of the cell cycle is G1, the presynthesis phase that prepares the cell for deoxyribonucleic acid (DNA) synthesis. The second phase is the S phase, whereby DNA synthesis occurs. Next is the G2 postsynthesis phase, in which the cell is prepared for mitosis. Cell division (cytokinesis) occurs in the fourth, or M (mitosis), phase. Cells may immediately progress to the G1 phase or enter the G0 or resting phase. Most cells in the human body are in the G0 stage. Exceptions include metabolically active cells (e.g., granulocytes) and epithelial cells found in the gastrointestinal tract. As each cell moves through the cell cycle, it must pass a number of checkpoints before it can continue its progression. If a cell is found to be defective at one of the checkpoints, it undergoes **apoptosis** (self-destruction). The cell cycle is illustrated in Figure XII-1.

GROWTH RATE

Growth rate (*doubling time*) is defined as the time it takes for a cancerous tumor to double in size. **Growth fraction** (the percent of actively dividing cells) decreases and doubling time increases as the tumor enlarges. Growth rate depends on several factors, including the cell-cycle activity of the proliferating cells in the tumor mass, the number of cells proliferating within the tumor (*growth fraction*), and the rate of cell loss from the tumor. In general, anticancer drugs are more effective against cancer cells that have a high growth fraction. Malignant tumors that have prolonged cell cycles and a slower growth rate are more likely to be locally confined and therefore are more amenable to surgical excision.

ANTICANCER THERAPY

Chemotherapy (chemical treatment) is the use of chemicals to kill cancer cells. Research has led to the use of new anticancer drugs and the development of standard treatment protocols (drug, dose, and schedule) to guide therapy. Nurses play a vital role in managing the treatment of those with cancer. This includes the administration of chemotherapy in health care facilities and in the homes of clients. To provide the best possible care, nurses should understand the chemotherapy regimen, contraindications, drug interactions, therapeutic effects, side effects, and adverse reactions of the chemotherapy that clients receive.

Chapter 37 discusses how selected anticancer drugs inhibit or prevent cell reproduction. The anticancer drugs are divided

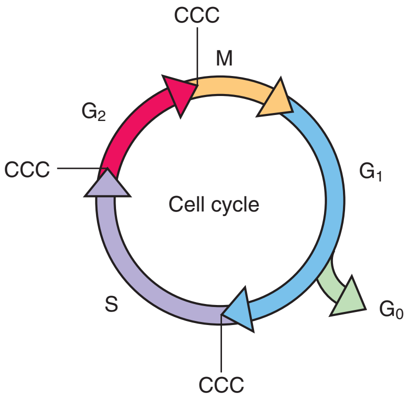

FIGURE XII–1 Cell division cycle and checkpoints. CCC, Cell cycle checkpoint. *G1 phase (postmitotic gap):* Production of enzyme for DNA synthesis. The G1 phase lasts 15 to 18 hours. *S phase (synthesis):* The DNA doubles. The S phase lasts 10 to 20 hours. G2 phase (premitotic gap): RNA synthesis for later mitosis. The G2 phase lasts approximately 3 hours. *M phase (mitosis):* Cell division produces two identical cells. The M phase lasts approximately 1 hour. *G0 phase (resting):* Cells remain in this phase or return to the cell cycle for cell replication. Cells in this phase are not as sensitive to many antineoplastic drugs. The cells must pass through a series of checkpoints to continue through the cycle. Cells that are defective undergo apoptosis (self-destruction).

into major classes that include alkylating agents, antimetabolites, antitumor antibiotics, mitotic inhibitors, and hormonal agents.

Some chemotherapy agents negatively affect cancer cells when they are actively dividing. These are called *cell cycle–specific (CCS) agents. Cell cycle–nonspecific (CCNS) drugs* work best in the G0 (resting) stage to disrupt cancer cells. Chemotherapy usually targets ribonucleic acid (RNA) or deoxyribonucleic acid (DNA) in cancer cells to prevent mitosis or induce apoptosis (self-death). The specific drugs selected are administered based on the type of tumor cells, the rate at which they divide, and the time that the drugs will be most effective. In general, chemotherapy is most effective in destroying cells that are rapidly dividing.

Chapter 38 explores targeted therapies to treat cancer. This modality targets malignant cells and is a recent development. Targeted therapies work by interfering with cancer-cell growth and division in different ways and at various points in the development, growth, and spread of cancer.

Chapter 39, describes the evolving state of biologic response modifiers that work to (1) enhance host immunologic function, (2) destroy or interfere with tumor activities, and (3) promote differentiation of stem cells.

OBJECTIVES

- Differentiate between cell cycle–specific and cell cycle–nonspecific anticancer drugs.
- Prioritize appropriate nursing interventions to use during the treatment of patients receiving anticancer drugs.
- Compare the uses and considerations for alkylating compounds, antimetabolites, antitumor antibiotics, hormones, and biotherapy agents.
- Contrast the guidelines for administering routine parenteral medications with IV chemotherapy preparation and administration.
- Discuss ways the nurse can avoid exposure to chemotherapeutic agents.
- Apply patient-centered collaborative care, including teaching, related to anticancer drugs.
- Develop a focused teaching plan about the uses and side effects of anticancer drugs.

Cancer-related deaths rank second only to heart disease in the United States. Even though cancer-related mortality has decreased since the early 1990s, 1 in 3 women and 1 in 2 men are projected to develop cancer over their lifetime. Excluding skin cancers, the highest incidence rates in men are prostate, lung, and colorectal cancer. In women, breast, lung, and colorectal cancers occur with the highest frequency. Lung cancer remains the leading cause of cancer-related death regardless of gender.

The incidence and mortality rates of cancer differ by ethnicity. African-American men have higher incidence and death rates from cancer than do white men. African-American women have a lower incidence of cancer than white women, but a higher mortality rate. Latinos have a lower incidence than non-Latinos, except for cancer of the stomach, liver, and cervix. Cancer among Asian Americans has traditionally been lower than other ethnic groups, but incidence increases as immigrants adopt a more westernized lifestyle. The incidence of liver and stomach cancer is higher among Asian immigrants, secondary to higher rates of chronic hepatitis B in this group.

Cancer is a group of diseases in which abnormal cells grow out of control and may spread to other areas of the body. Deoxyribonucleic acid (DNA) is the genetic substance in the body cells that transfers information necessary for the production of enzymes and protein synthesis. In most cases, cancer is caused by damage to the DNA within the cell. Although some cancers are inherited, most develop when genes in a normal cell become damaged or lost (mutation). More than one mutation is required before a malignancy can develop. Therefore the development of cancer is a multistep process that may take years to complete.

Pharmaceuticals are often used to destroy cancer cells and are called by different names, including *anticancer drugs, cancer chemotherapeutic agents,* **antineoplastic drugs,** or **cytotoxic therapy**. In the 1970s, the use of two or more chemotherapy agents (**combination chemotherapy**) to treat cancer was adopted and led to improved response rates and increased survival times. Chemotherapy may be used as the sole treatment of cancer or in conjunction with other modalities (e.g., radiation, surgery, biologic response modifiers). Combination chemotherapy has proved to be effective in curing some cancers. When cancer cannot be cured, anticancer drugs may be given to control the disease for a period of months to years. If cancer can no longer be controlled, chemotherapy may be used to relieve disease-related symptoms or improve quality of life. This is called *palliative treatment*.

GENETIC, INFECTIVE, ENVIRONMENTAL, AND DIETARY INFLUENCES

Cancer is a genetic disease. Genes provide the instructions for the production and function of cellular proteins that are essential for normal cellular activities. Genetic defects may occur in a variety of ways, including deletion, translocation, duplication, inversion, or insertion of genetic material. When these defects cannot be effectively repaired, cells exhibit abnormal characteristics and unregulated growth. More than 2000 genes have been causally implicated in the formation of cancer. Cancers that have a proven genetic influence include breast, ovarian, prostate, endometrial, colon, pancreatic, and lung cancers; retinoblastoma; and malignant melanoma. Many more genetic influences are expected to be found. Environment, lifestyle, viruses, and diet can influence the development of these and other types of cancers. Box 37-1 gives examples of types of environmental products, viruses, and foods that have a carcinogenic effect on cancer development in humans.

Genes can cause cells to become cancerous in several ways. *Proto-oncogenes* are normal genes that are involved in the controlled growth, division, and death (**apoptosis**) of cells. An oncogene is a mutation in a proto-oncogene. An abnormal oncogene can effect cellular growth-control proteins and trigger unregulated cell division. Tumor-suppressor (TS) genes (anti-oncogenes) signal a cell to cease multiplying and act to stop the action of oncogenes. If TS genes become lost or dysfunctional, cells could reproduce uncontrollably. Other genes repair damage to DNA. If these DNA-repair genes are damaged, mutations are not mended and are subsequently passed on to the next generation of daughter cells. It may take a long time before sufficient cell mutations take place and cause cancer to develop. As a result, cancers more commonly occur in older individuals.

A number of viruses are associated with the development of cancer. The human papillomavirus (HPV) has been found in most women with invasive cervical cancer. Individuals with human immunodeficiency virus (HIV) may develop lymphomas and anal or genital cancers. The Epstein-Barr virus is found in almost all people with Burkitt's lymphoma in central Africa. This virus has been implicated in the development of nasopharyngeal cancer. Hepatocellular carcinoma (liver cancer) is linked to the hepatitis B or C virus. Other viruses that have a link to the development of cancer include human T-cell lymphotropic virus, type 1 (HTLV-1); human T-cell lymphotropic virus, type 2 (HTLV-2); and Kaposi sarcoma–associated herpes virus.

BOX 37-1 ENVIRONMENTAL, INFECTIVE, AND DIETARY INFLUENCES ON CANCER DEVELOPMENT

Environmental

Tobacco

Cancer of the lung, larynx, bladder, kidney, colon, cervix, stomach, pancreas, breast

Asbestos

Lung cancer

Benzene

Acute myelogenous leukemia

Formaldehyde

Nasopharyngeal cancer, leukemia

Vinyl Chloride

Sarcoma

Arsenic

Cancer of the lung, skin; sarcoma

Ionizing Radiation

Leukemia; cancer of the thyroid, breast

Ultraviolet Rays

Skin cancer

Aflatoxin

Liver cancer

Infective

Herpes Simplex 2 Virus (Genital Herpes)

Cancer of the cervix

Hepatitis B and Hepatitis C Viruses

Cancer of the liver

Epstein-Barr Virus (a cause of infectious mononucleosis)

Non-Hodgkin's lymphoma, Hodgkin's disease, nasopharyngeal cancers

Human Papilloma Virus (HPV)

Cancer of the cervix, vulva, vagina, anus, head and neck

Human Immunodeficiency Virus (HIV)

Kaposi sarcoma, Non-Hodgkin's lymphoma, cervical cancer

Human T-Cell Lymphotrophic Virus

T-cell leukemia

Helicobacter pylori

Cancer of the stomach, gastric mucosa-associated lymphoid tissue (MALT) lymphoma

Diet

Animal Fat

Cancer of the colon, rectum, breast, uterus, prostate, ovary

Heterocyclic Amines (found in some smoked meats)

Cancer of the stomach, colon, rectum, pancreas, breast

Alcohol

Cancer of the mouth, throat, esophagus, liver, breast

Bacteria can play a role in the development of cancer. The presence of *Helicobacter pylori* in the stomach is associated with an increased risk of developing gastric cancer. Some reports have indicated a link between certain bacteria and cancer of the gallbladder, colon, and lung. However, evidence that supports an association between bacterial infection and other cancers is unclear.

Environmental factors associated with the development of cancer include tobacco use, diet, infectious agents, chemicals, excessive sun exposure, and radiation. According to the American Cancer Society (ACS), the use of tobacco, an unhealthy diet, and inadequate physical activity account for 75% of cancer cases and deaths in the United States.

CELL CYCLE–NONSPECIFIC AND CELL CYCLE–SPECIFIC ANTICANCER DRUGS

The cell cycle for normal and cancer cells, growth fraction, and doubling time are discussed in Unit XII (see Figure XII-1). See the discussion at the beginning of Unit XII for clarification of the cell cycle and definitions.

Anticancer drugs cause cell death by interfering with cell replication and are classified according to their action on the cell. **Cell cycle–nonspecific (CCNS) drugs** (phase-nonspecific drugs) act during any phase of the cell cycle, including the G0 phase. **Cell cycle–specific (CCS) drugs** (phase-specific drugs) exert their influence during a specific phase or phases of the cell cycle. CCS agents are most effective against rapidly growing cancer cells. In general, the CCNS drugs include the alkylating drugs (although some alkylating agents are CCS), antitumor antibiotics, and hormones. The CCS drugs include antimetabolites and vinca alkaloids. Figure 37-1 shows selected types of anticancer drugs and the phase of the cell cycle in which they are most effective.

Growth fraction and **doubling time** are two factors that play a major role in the response of cancer cells to anticancer drugs. Anticancer drugs are more effective against neoplastic cells that have a high growth fraction (i.e., a high percentage of actively dividing cells). Leukemias and some lymphomas have high growth fractions and thus respond well to anticancer drug therapy.

Solid tumors have a large percentage of their cell mass in the G0 phase, so they generally have a low growth fraction and are less sensitive to anticancer drugs. High-dose chemotherapy results in better tumoricidal (tumor-killing) effects. Depending on the type of cancer, malignant cell growth is usually faster in the earlier stages of tumor development. As

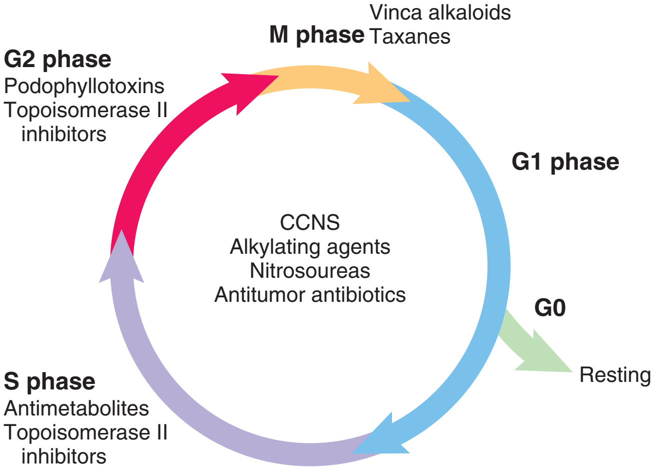

FIGURE 37–1 Selected anticancer drugs and the phases of the cell cycle in which they are most effective.

the tumor grows, the blood supply decreases, thereby slowing the growth rate. Anticancer agents are more effective against small, fast growing tumors with sufficient blood supply. As the tumor enlarges, its growth fraction decreases and its doubling time increases, reducing the effectiveness of anticancer therapy. The vascularization in solid tumors can be inconsistent. Some areas of tumor may have an adequate blood supply, while other areas are poorly perfused. This characteristic may make some large tumors resistant to anticancer drugs and therefore difficult to treat.

CANCER CHEMOTHERAPY

Anticancer drugs are not selective, so both cancer cells and normal cells are affected. The side effects of chemotherapy are largely related to the toxic effects on normal cells. Antineoplastic agents are effective because normal cells are able to repair themselves and continue to grow, whereas cancer cells are less able to do so; thus, the side effects of chemotherapy are most often temporary. Chemotherapy is usually administered systemically for cancer that has spread to other parts of the body, for tumors in multiple sites, or for tumors that are too large to be removed through other means (e.g., surgery). The most common route of chemotherapy administration is via intravenous (IV) infusion, although other routes may be used, including oral, intramuscular, subcutaneous, intraperitoneal, intraventricular (intrathecal), intrapleural, intravesicular, intra-arterial, or topical.

Some types of cancer can be cured with chemotherapy (e.g., Hodgkin's disease, Burkitt's lymphoma, testicular cancer). Other types of cancer (e.g., breast cancer, colon cancer) may be treated with surgery first, followed by chemotherapy to eliminate any residual tumor cells (microscopic metastases) that may remain in the body. This is referred to as **adjuvant therapy.** Sometimes **neoadjuvant chemotherapy** may be given first to help shrink a large tumor, so that it can be surgically removed. **Palliative chemotherapy** is used to relieve symptoms associated with advanced disease (e.g., pain, shortness of breath) and improve quality of life.

Chemotherapy administration is guided by specific **protocols** that were developed based on the results of controlled research studies. The length of treatment is determined by the type and extent of the malignancy, type of chemotherapy given, expected side effects of these drugs, and the amount of time that normal cells need to recover. Chemotherapy is usually given in cycles to improve the likelihood that cancer cells will be destroyed and that normal cells can recover. The duration, frequency, and number of cycles of chemotherapy are based on the type and size of the tumor, whether the disease has spread to other areas of the body (**metastasis**), and the condition of the patient. Chemotherapy treatment may consist of one agent or a combination of agents. Combination chemotherapy may be administered on one day or spread out over several days. The duration of each treatment varies from minutes to days and may be repeated weekly, biweekly, or monthly, based on the protocol being followed. Selected anticancer/antineoplastic drugs are listed in Box 37-2 according to classification.

Combination Chemotherapy

Single-agent drug therapy is not usually used to treat cancer, because combinations of anticancer agents have demonstrated more effective tumoricidal activity. Chemotherapy is most effective when it is able to kill cells in all phases of the cell cycle. Using two or more chemotherapy drugs at a time (combination chemotherapy) makes this more likely to occur.

To maximize cell death, CCS and CCNS drugs are often combined. Each individual chemotherapy agent used in combination therapy should have proven tumoricidal activity. Using two or more drugs together may have a synergistic effect. In addition, each drug should have a different mode of action and different dose-limiting toxicities. The use of a combination of antineoplastic agents has the advantage of decreasing drug resistance and increasing destruction of cancer cells. Some of the combinations of anticancer drugs used in cancer treatment are presented in Table 37-1.

General Side Effects and Adverse Reactions

Anticancer drugs exert adverse effects on rapidly growing normal cells (e.g., skin, hair). These drugs can also affect cells in the gastrointestinal (GI) tract, mucous membranes, bone marrow, and reproductive system. When there is a significant decrease in the cells in the bone marrow (white blood cells, platelets, red blood cells) the condition is called **myelosuppression**. Following chemotherapy administration, the time at which the blood count is at the lowest is called the **nadir** and typically occurs 7 to 10 days after treatment. Table 37-2 lists the general adverse reactions to anticancer drugs on the fast-growing cells of the body. Selected nursing measures and considerations are included.

Anticancer Therapy in Outpatient Settings and in the Home

The administration of anticancer drugs in outpatient settings is cost-effective and convenient. Although chemotherapy regimens have become increasingly aggressive, most patients

BOX 37-2 ANTICANCER DRUGS BY CLASSIFICATION*

Alkylating Agents

Mustard Gas Derivatives

nitrogen mustard (mechlorethamine hydrochloride) (Mustargen)
chlorambucil (Leukeran)
cyclophosphamide (Cytoxan)
ifosfamide (Ifex)
melphalan (Alkeran)
temozolomide (Temodar)

Nitrosoureas

carmustine (BiCNU, BCNU, Gliadel)
lomustine (CeeNU, CCNU)
streptozocin (Zanosar)

Alkylating-Like Agents

altretamine (Hexalen)
carboplatin (Paraplatin)
cisplatin (Platinol)
dacarbazine (DTIC)
oxaliplatin (Eloxatin)
thiotepa (Thioplex)

Alkyl Sulfonates

busulfan (Myleran, Busulfex))

Antimetabolites

Folic Acid Antagonists

methotrexate (MTX, amethopterin, Folex, Mexate)
pemetrexed disodium (Alimta)
trimetrexate glucuronate (Neutrexin)

Pyrimidine Analogues

azacitidine (Vidaza)
capecitabine (Xeloda)
cytarabine HCl (Cytosar-U, ARA-C)
decitabine (Dacogen)
floxuridine (FUDR)
fluorouracil (5-FU, Adrucil)
gemcitabine HCl (Gemzar)
nelarabine (Arranon)

Purine Analogues

cladribine (Leustatin)
clofarabine (Clolar)
fludarabine (Fludara)
6-mercaptopurine (6-MP, Purinethol)
thioguanine (Lanvis)

Ribonucleotide Reductase Inhibitors (Enzyme Inhibitors)

hydroxyurea (Hydrea)
2-deoxycoformycin (pentostatin [Nipent]

Plant Alkaloids

Vinca Alkaloids

vinblastine sulfate (Velban)
vincristine sulfate (Oncovin)
vincristine (liposomal) (Marqibo)
vinorelbine (Navelbine)

Antimicrotubules or Taxanes

docetaxel (Taxotere)
paclitaxel (Taxol)

Podophyllotoxins

etoposide (VP-16, Vepesid)
teniposide (VM-26, Vumon)

Camptothecan Analogs

Irinotecan (Camptosar, CPT-11)
Topotecan (Hycamtin)

Retinoids

bexarotene (Targretin)
thalidomide (Thalomid)

Antitumor Antibiotics

bleomycin sulfate (Blenoxane)
dactinomycin (Actinomycin D, Cosmegen)
daunorubicin HCl (Cerubidine)
daunorubicin (liposomal) (DaunoXome)
doxorubicin (Adriamycin, Rubex)
doxorubicin HCl (liposomal) (Doxil, Caelyx, Myocet)
epirubicin (Ellence)
idarubicin (Idamycin)
mitomycin (Mutamycin)
mitoxantrone (Novantrone)
valrubicin (Valstar)

Hormones, Hormonal Antagonists, and Enzymes

Androgens

testolactone (Teslac)
progesterone (Gesterol 50)

Hormonal Antagonists and Enzymes

aminoglutethimide (Cytadren)
anastrozole (Arimidex)
bicalutamide (Casodex)
exemestane (Aromasin)
flutamide (Eulexin)
fulvestrant (Faslodex)
goserelin acetate (Zoladex)
histrelin acetate implant (Vantas)
letrozole (Femara)
leuprolide acetate (Lupron)
megestrol acetate (Megace)
mitotane (Lysodren)
nilutamide (Nilandron)
raloxifene hydrochloride (Evista)
tamoxifen citrate (Nolvadex) (nonsteroidal antiestrogen)
toremifene (Fareston)

Miscellaneous

Enzymes

L-asparaginase (Elspar)
pegaspargase (Oncaspar)

Vaccines

Recombinant vaccines Gardasil and Cervarix

High-Alert Medications

All chemotherapeutic agents are categorized as high-alert medications for all routes of chemotherapeutic drug delivery.

*See Chapter 38 for monoclonal antibodies and targeted therapies and Chapter 39 for biologic therapies.

TABLE 37-1 SELECTED COMBINATIONS OF ANTICANCER DRUGS

GENERIC (BRAND)	ACRONYM*	SELECTED USES
doxorubicin (Adriamycin), bleomycin (Blenoxane), vinblastine (Velban), dacarbazine (DTIC)	ABVD	Hodgkin's lymphoma
fluorouracil (5-FU, Adrucil), doxorubicin/hydroxydoxorubicin (Adriamycin), cyclophosphamide (Cytoxan)	FAC*	Breast cancer, prostate cancer
cyclophosphamide (Cytoxan), doxorubicin/hydroxydoxorubicin (Adriamycin), methotrexate (Rheumatrex, Trexall)	CAM	Prostate cancer
cyclophosphamide (Cytoxan), epirubicin (Pharmorubicin), fluorouracil (5-FU, Adrucil)	CEF	Breast cancer
cyclophosphamide (Cytoxan), doxorubicin/hydroxydoxorubicin (Adriamycin), vincristine (Oncovin), prednisone, rituximab (Rituxan)	CHOP + rituximab (CHOP+R)	Non-Hodgkin's lymphoma
etoposide (VePesid, VP-16), leucovorin, fluorouracil (5-FU, Adrucil)	ELF	Esophageal cancer, stomach cancer
folinic acid (leucovorin), fluorouracil (5-FU, Adrucil), irinotecan (Camptosar)	FOLFIRI	Colorectal cancer
folinic acid (leucovorin), fluorouracil (5-FU, Adrucil), oxaliplatin (Eloxatin)	FOLFOX	Colorectal cancer
gemcitabine (Gemzar), capecitabine (Xeloda)	GEMCAP	Cancer of the pancreas
idarubicin (Idamycin), cytarabine (ARA-C, Cytosar), etoposide (VP-16, VePesid)	ICE	Acute myelogenous leukemia
mechlorethamine (Mustargen), vincristine (Oncovin), procarbazine (Matulane), prednisone	MOPP	Hodgkin's disease
melphalan (Alkeran), prednisone	MP	Multiple myeloma
mitomycin C (Mutamycin), vinblastine (Velban), cisplatin (Platinol)	MVP	Small cell lung cancer
paclitaxel (Taxol), carboplatin (Paraplatin)	PC	Non–small cell lung cancer
docetaxel (Taxotere), doxorubicin (Adriamycin), cyclophosphamide (Cytoxan)	TAC	Recurrent breast cancer
vinblastine (Velban), bleomycin (Blenoxane), cisplatin (Platinol)	VBP	Testicular cancer

*Acronyms are based on the name of the chemotherapy agents used in a specific protocol (e.g., ABVD [Adriamycin, bleomycin, vinblastine, dacarbazine], FAC [fluorouracil, Adriamycin, cyclophosphamide]). Both generic and trade names are used in acronyms.

are not hospitalized unless they require close monitoring or are very ill. Some chemotherapy agents are administered in the home. Patients receiving highly potent drugs at home may need to be closely monitored for severe adverse reactions or to assure adequate hydration. When a chemotherapy drug is given in the home, a health care provider qualified to administer anticancer agents follows the policies provided by the oncologist and the home health care agency. To reduce the nurse's exposure to chemotherapy drugs (hazardous drugs, or HD) during intravenous (IV) administration, the following precautions should be followed to minimize occupational exposure:

- Use disposable powder-free gloves (nitrile, polyurethane, neoprene) that have been tested with HD when handling chemotherapy, regardless of route of administration.
- Wear gowns (disposable, impermeable, lint-free) during the administration of IV chemotherapy.
- When there is a risk of aerosol exposure, a National Institute for Occupational Safety and Health–approved respirator is necessary. Surgical masks do not provide adequate respiratory protection.
- Use a face shield or a combination of mask and face shield if there is a danger of splashing when administering chemotherapy or disposing of body fluids.
- Change gloves after chemotherapy administration and if they become contaminated or punctured.
- Cytotoxic drugs can be accidentally absorbed by inhalation, contact with skin or mucous membranes, and ingestion. The following guidelines should be followed:
  1. Prepare chemotherapy in a separate work area. Use a plastic-backed absorbent pad to contain spills during preparation.
  2. Wash hands before and after administration of chemotherapy.
  3. Avoid hand-to-mouth or hand-to-eye contact while working with chemotherapy.
  4. Refer to agency policy for priming IV tubing and disconnecting tubing after administration.
  5. Wear gloves when disposing of body fluids (e.g., urine, feces, emesis) of patients who have received chemotherapy in the previous 48 hours.
  6. Refer to agency policy for disposal of used equipment.
  7. Refer to agency policy for chemotherapy spills or exposure.

ALKYLATING DRUGS

One of the largest groups of anticancer drugs is the alkylating compounds. **Alkylating agents** cause cross-linking of DNA strands, abnormal base pairing, or DNA strand breaks, thus preventing the cell from dividing. Drugs in this group belong to the CCNS category and kill cells in various and multiple phases of the cell cycle. However, they are most effective against cells in the G0 phase. Alkylating agents are effective against many types of cancer, including acute and chronic leukemias, lymphomas, multiple myeloma, and solid tumors (e.g., breast, ovary, uterus, lung, bladder, and stomach). Drugs in this category are classified into several groups: mustard gas derivatives (e.g., cyclophosphamide [Cytoxan]), ethylenimines (e.g., thiotepa [Thioplex]), alkylsulfonates (e.g., busulfan [Myleran]), triazines (e.g., dacarbazine [DTIC]), nitrosoureas (e.g., carmustine [BiCNU]), and metal salts (e.g., cisplatin [Platinol]). Nitrosoureas are unique because they can cross the blood-brain barrier, making them useful in the treatment of brain cancer. Table 37-3 lists the alkylating drugs, uses, and considerations.

TABLE 37-2 GENERAL ADVERSE REACTIONS TO ANTICANCER DRUGS

ADVERSE REACTIONS	NURSING MEASURES AND CONSIDERATIONS
Bone Marrow Suppression, Myelosuppression	
Low RBC count (anemia)	Assess for fatigue, shortness of breath, low blood pressure, increased heart rate, increased respiratory rate, and oliguria. Assess for cyanosis. Plan rest periods. Administer oxygen as prescribed. Elevate head of bed to facilitate breathing. Provide pain mediation if pain is increasing oxygen consumption. Provide assistance to bathroom. Monitor for mental status changes. Anemia may be treated with ferrous sulfate or infusions of RBCs. Erythropoietin may be administered to stimulate RBC production.
Low WBC count (neutropenia)	Susceptibility to infection increases as WBCs decrease. Visitors with colds or infections should take precautions (e.g., wear mask) or avoid visiting the patient. Report fever, chills, upper respiratory infections, or sore throat to health care provider. Health care providers and visitors should wash hands before and after contact with the patient. Neutrophils are the primary WBCs that fight infections. Usual signs of infection (pain, swelling, redness, warmth, pus) may be absent or greatly reduced in neutropenic patients. Monitor for increase (or decrease) in body temperature. Elevated temperature is considered a sign of infection. Avoid medications that may mask temperature. Immediately report temperatures of 101° F (38.3° C) or above to health care provider. Appropriate cultures (e.g., blood, urine, sputum) are collected, and an antibiotic regimen is initiated. Assess for localized infections. Auscultate breath sounds. Monitor WBC count. Colony-stimulating factors (e.g., filgrastim) may be administered to stimulate WBC production.
Low platelet count (thrombocytopenia)	Petechiae, bruising, bleeding of gums, and nosebleeds are signs of a low platelet count; report these signs to health care provider. Assess for bleeding, petechiae, and ecchymosis. Assess for occult bleeding in urine, feces, and emesis. Monitor platelet counts and bleeding time. Apply pressure to injection sites. Platelet transfusions may be needed. Avoid medications that may promote bleeding (e.g., aspirin). Avoid invasive procedures (e.g., injections, indwelling urinary catheters, rectal temperature).
GI Disturbances	
Anorexia	Loss of appetite may be related to anemia, pain, fatigue, or bitter taste caused by some chemotherapy agents. Provide small, frequent meals that are high in calories and protein. Plan rest periods. Address issues of pain control. Hard candy or ice chips may help relieve bitter taste.
Nausea and vomiting	Antineoplastic drugs often stimulate the chemoreceptor trigger zone (CTZ), leading to nausea and vomiting. Nausea and vomiting (N/V) may be caused by irritation of GI tract; effects of radiation to chest, abdomen, or brain; anxiety; constipation; pain; electrolyte imbalances; or other medications. Grading scales are useful to assess severity. Provide antiemetics before, during, and after chemotherapy. Assess for GI upset, and medicate appropriately. Minimize noise, stimulation, and odors. Frequent mouth care is recommended.
Diarrhea	Diarrhea may be one of three types: osmotic (absorption defects), secretory (bacterial infection, neoplasm), or exudative (secondary to chemotherapy). Chemotherapeutic agents most commonly associated with diarrhea are alkylating agents, antitumor antibiotics, and antimetabolites. Treatment (e.g., medications, diet changes) will depend on cause. Diarrhea may be caused by other medications (e.g., antibiotics); comorbid conditions (e.g., Crohn's disease); or enteral feedings (e.g., tube feeding). Assess normal bowel habits; monitor for electrolyte imbalances and dehydration. Administer appropriate antidiarrheal medications (e.g., antibiotics, anticholinergics, antispasmodics, psyllium, kaolin and pectin, octreotide acetate). Teach patient to eat small, frequent meals; follow a low-residue diet; limit spicy, fatty foods; limit intake of salty foods, whole grains, fresh fruits and vegetables; limit caffeine and carbonated drinks; and avoid very hot or very cold foods (may stimulate peristalsis). Monitor intake and output. A grading scale may be useful to assess severity.
Mucositis (stomatitis)	Many antineoplastic agents cause changes in oral mucosa; generally occur 2 to 14 days after initiation of therapy. Assess for taste changes, tissue swelling, redness, pain, dry mouth, white patches, or a white coating on the oral mucosa. Mucositis ranges from mild to severe. Symptomatic treatment may include frequent mouth rinses, topical anesthetics, antibiotics, antifungal medication, saliva substitutes, and pain medication. Patient should avoid commercial mouthwashes that contain alcohol. A soft toothbrush is recommended. Offer ice chips or ice pops to help relieve pain. Assess intake and output. Evaluate caloric needs. A grading scale may be useful to assess severity.
Other	
Alopecia	Not all chemotherapeutic agents cause hair loss. Hair thinning, patchy baldness, or complete alopecia may occur, depending on drug. Hair on all areas of the body is affected. Hair loss may be gradual (progressing with each cycle of chemotherapy) or rapid. Hair regrowth usually occurs once chemotherapy is completed; texture may be somewhat changed. Before therapy, discuss potential hair loss and ways to address problem (wigs, scarves, hats, turbans). Assess for body image changes, concerns.
Fatigue	Fatigue may be caused by chemotherapy, sleep disturbances, emotional distress, depression, bone marrow suppression, infection, pain, or electrolyte imbalances. Assess fatigue using a visual analogue scale (0 = no fatigue; 10 = worst fatigue). Address conditions that might be contributing to fatigue (e.g., lack of sleep, pain, depression). Plan ways to help patient conserve energy. Plan a well-balanced diet. Encourage patient to participate in regular (but not strenuous) exercise. Encourage stress-reduction measures (e.g., relaxation, guided imagery). A grading scale may be useful in assessing fatigue.
Infertility	If infertility occurs, it may be permanent. Pretreatment counseling is advised.

GI, Gastrointestinal; *RBC,* red blood cell; *WBC,* white blood cell.

TABLE 37-3 ANTINEOPLASTICS: ALKYLATING DRUGS

DRUG TYPE AND NAME	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Nitrogen Mustards		
chlorambucil (Leukeran)	PO: 0.1-0.2 mg/kg/d (equals 4-8 mg/m^2/d) for 3-6 wk	Lymphocytic leukemia, lymphomas, and cancer of the breast and ovaries. Side effects include nausea, vomiting, anorexia, diarrhea, abdominal upset, and leukopenia. Pregnancy category: D; PB: 99%; t½: 1.5 h
cyclophosphamide (Cytoxan)	See Prototype Drug Chart 37-1.	
ifosfamide (Ifex)	IV: 1.2-2 g/m^2/d for 5 d in combination with mesna	Testicular cancer, lymphoma, lung cancer, and sarcomas. Mesna, an uroprotective agent, is added to prevent hemorrhagic cystitis. Pregnancy category: D; PB: 69%-75%; t½: 7-15 h (high dose)
mechlorethamine HCl (Mustargen)	IV: 0.4 mg/kg, or 12-16 mg/m^2 Intracavitary: 0.2-0.4 mg/kg Topical: Dilute 10 g in 60 mL sterile water, apply with gloves (use precautions)	Hodgkin's disease, solid tumors, and pleural effusion caused by cancer of the lung. Similar side effects as chlorambucil. Pregnancy category: D; PB: UK; t½: 1 min
melphalan (Alkeran)	For multiple myeloma: 0.25 mg/kg/d; repeat every 6 wk For bone marrow transplant: IV 50-60 mg/m^2	Multiple myeloma, melanoma, and cancers of the breast, ovary, and testes. Pregnancy category: D; PB: 30%; t½: 1.5 h
temozolomide (Temodar)	PO: 150/mg/m^2/d; repeat every 28 d	Refractory anaplastic astrocytoma. Pregnancy category: D; PB: 15%, t½: UK
Nitrosoureas		
carmustine (BiCNU, BCNU)	IV: 75-100 mg/m^2/d for 2 d	Hodgkin's disease, multiple myeloma, melanoma, and brain tumors. May be used for cancer of the breast and lung. Nausea, vomiting, and stomatitis may occur. Pregnancy category: D; PB: UK; t½: 15-30 min
lomustine (CeeNu, CCNU)	PO: 130 mg/m^2 every 6 wk	Advanced Hodgkin's disease and brain tumors. Pregnancy category: D; PB: 50%; t½: 1-2 d
streptozocin (Zanosar)	IV: 500 mg/m^2/d for 5 d, repeat every 3-4 wk	Pancreatic islet cell tumor and cancer of the lung. May also be used for Hodgkin's disease and colorectal cancer. Nausea, vomiting, diarrhea, and leukopenia may occur. Pregnancy category: C; PB: UK; t½: 30-45 min
Alkyl Sulfonates		
busulfan (Myleran, Busulfex)	PO: 4-8 mg/d for 2-3 wk initially; then maintenance dose IV: 0.8 mg/kg	Myelocytic leukemia. Monitor WBCs closely. May be used as preparation agent in bone marrow transplant. Pregnancy category: D; PB: UK; t½: 2.5 h
Alkylating-Like Drugs		
altretamine (Hexalen)	PO: 260 mg/m^2/d in 4 equally divided doses for 14 d or 21 d	Ovarian cancer. Also used for breast, cervix, colon, endometrial, head/neck, and lung cancers; lymphomas. Nausea and vomiting and peripheral neuropathy may occur. Pregnancy category: D; PB: 6%; t½: 13 h
carboplatin (Paraplatin)	IV: 360 mg/m^2 every 4 wk Intraperitoneal: 200-650 mg/m^2 in 2 L For bone marrow transplant 1600 mg/m^2 IV in divided doses over 4 d	Recurrent ovarian cancer. May be used as preparation agent in bone marrow transplant. Pregnancy category: D; PB: 0%; t½: 2-6 h
cisplatin (Platinol)	IV: 50-100 mg/m^2 every 3-4 wk For ovarian cancer: intraperitoneal: 100 mg/m^2 every 3 wk	Ovarian and testicular cancer. Used as adjunctive treatment. Has been used for cancer of the bladder, head and neck, and endometrium. Nausea, vomiting, peripheral neuropathy, stomatitis, tinnitus, and blurred vision may occur. Ototoxicity occurs in 30% of patients. Pregnancy category: D; PB: >90%; t½: 58-75 h
oxaliplatin (Eloxatin)	IV: 85-130 mg/m^2 infusion in 200-250 mL 5% dextrose in water	Metastatic colorectal cancer. Used with 5-FU and leucovorin. Ovarian cancer, head and neck cancer, and malignant melanoma. Pregnancy category: D; PB: >90%; t½: 20-40 d

Continued

TABLE 37-3 ANTINEOPLASTICS: ALKYLATING DRUGS—cont'd

DRUG TYPE AND NAME	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
dacarbazine (DTIC)	IV: 375 mg/m^2 every 2 wk	Metastatic malignant melanoma, sarcomas, neuroblastoma, and refractory Hodgkin's disease. May be given as an IV bolus (push) or by IV infusion. Common side effects are anorexia, nausea, and vomiting. Pregnancy category: C; PB: 5%-10%; $t_{1/2}$: 5 h
thiotepa (Thioplex)	IV: 0.3-0.4 mg/kg IV once every 1-4 wk Intracavitary: Bladder: 60 mg in 30-60 mL of sterile water weekly for 3-4 wk Effusions: 0.6-0.8 mg/kg every 1-4 wk	Palliative therapy, especially for breast and ovarian cancer. Pregnancy category: D; PB: UK; $t_{1/2}$: 1.5-2 h

Note: Chemotherapeutic doses and schedules will vary depending on protocol, body surface area (m^2), age, functional status, and comorbid conditions. For a full discussion of body surface area in dosage calculation, see Chapter 14.

5-FU, Fluorouracil; *d,* day; *FDA,* U.S. Food and Drug Administration; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *min,* minute; *PB,* protein-binding; $t_{1/2}$, half-life; *UK,* unknown; *WBC,* white blood cell; *wk,* week; >, greater than; <, less than.

The side effects for alkylating drugs include nausea, vomiting, hemorrhagic cystitis, alopecia, anemia, leukopenia, thrombocytopenia, bone marrow suppression (anemia, leukopenia, thrombocytopenia), secondary malignancies, and sterility. Major dose-limiting toxicities may occur in the blood cell line (red blood cell, white blood cell, platelet) and urinary systems. General adverse reactions to chemotherapeutic drugs are listed in Table 37-2.

Cyclophosphamide

Mechlorethamine (nitrogen mustard, [Mustargen]), the first alkylating drug introduced for cancer treatment, became available for clinical use during World War II. Mechlorethamine is administered as part of a chemotherapy regimen to treat Hodgkin's disease, especially if the disease is resistant to other drug combinations. This drug is a severe **vesicant** that can cause tissue necrosis if it infiltrates into the tissues. Cyclophosphamide (Cytoxan), an analogue of nitrogen mustard, may be prescribed orally, intrapleurally, or IV. The patient should be well hydrated while taking this drug to prevent hemorrhagic cystitis (bleeding as a result of severe bladder inflammation). MESNA (2-mercaptoethane sulphonate sodium [MESNEX]) is a **cytoprotectant (chemoprotectant)** drug that is often given with high-dose cyclophosphamide to inactivate urotoxic metabolites in the bladder and minimize damage to this organ.

SAFETY: Preventing Medication Errors

Do not confuse ...

- **Cytoxan** (cyclophosphamide) with **Cytosar** (cytosine arabinoside)

Pharmacokinetics Cyclophosphamide is well absorbed from the GI tract. Its half-life is moderate, and it is moderately protein-bound (<60%). The drug is metabolized by the liver, and less than 50% is excreted unchanged in the urine.

Pharmacodynamics Cyclophosphamide, an early antineoplastic drug, is still prevalent in chemotherapy protocols to treat breast cancer, leukemia, lymphoma, multiple myeloma, ovarian cancer, retinoblastoma, and neuroblastoma. The onset of action begins in 2 to 3 hours; however, therapeutic effect may take several days. It is one of the anticancer drugs that can be administered orally.

Several drug interactions may occur with cyclophosphamide. Patients should report all medications they are taking, including over-the-counter (OTC) medicines and herbal supplements. Serious drug interactions can occur when taking cyclophosphamide and aspirin, the gout medication allopurinol (Lopurin, Zyloprim), phenobarbital (Luminal), warfarin (Coumadin), thiazide diuretics, and some psychiatric medications. Herbal Alert 37-1 lists herbal supplements that may also interact with cyclophosphamide.

HERBAL ALERT 37-1

Cyclophosphamide

- Use cautiously with garlic (antiplatelet activity), ginkgo (increased antiplatelet effect), echinacea (decreased effects of immunosuppressive drugs), ginseng (altered bleeding time), St. John's wort (may interfere with chemotherapy), and kava kava (increased risk for bleeding). Toxicity and actions of both cyclophosphamide and vitamin A are altered if given together. *Do not use with mistletoe because it may promote cancer growth.*
- Astragalus (Huang-qi; milk vetch root) stimulates the immune system and may help speed recovery from immunosuppressive chemotherapy. Astragalus has blood clot–fighting properties and may increase risk of bleeding when given with cyclophosphamide.

Side Effects and Adverse Reactions

The side effects of cyclophosphamide reflect those seen in this general class of antineoplastic drugs. Hemorrhagic cystitis is a serious problem that can arise when high doses of cyclophosphamide are given. Patients who receive a high dose should be assessed for cardiomyopathy and syndrome of inappropriate antidiuretic hormone secretion (SIADH) during treatment with this drug. In addition, cyclophosphamide may cause a change (darkening) in the skin or fingernails. Prototype Drug Chart 37-1 details the pharmacologic behavior of cyclophosphamide.

PROTOTYPE DRUG CHART 37-1

Cyclophosphamide

Drug Class

Alkylating drug

Trade Name: Cytoxan

Pregnancy Category: D

Dosage

A: PO: Initially: 1-5 mg/kg over 2-5 d

IV: Initially: 40-50 mg/kg in divided doses over 2-5 d; *max:* 100 mg/d; C: PO/IV: Initially: 1-5 mg/kg in divided doses or 50-150 mg/m^2

Many other dose regimens are used. Dose varies based on indicated use.

Adjust dose if bone marrow suppression (myelosuppression) occurs.

Contraindications

Hypersensitivity, severe myelosuppression

Caution: Pregnancy, liver or kidney disease

Drug-Lab-Food Interactions

Drug: Decreases digoxin level. Increases drug action of barbiturates, chloramphenicol half-life, and effects of anticoagulant drugs. Duration of leukopenia may be prolonged if given with thiazide diuretics. Potentiates doxorubicin (Adriamycin) cardiomyopathy. Actions and toxicities of allopurinol, probenicid, colchicine, phenothiazines, potassium iodide, imipramine, warfarin, and succinylcholine are altered if given with cyclophosphamide. Toxicity increased if given with corticosteroids, phenytoin, or sulfonamides.

Herb: Use cautiously with garlic, ginkgo, echinacea, ginseng, St. John's wort, kava kava, grapeseed. Toxicity and actions of both cyclophosphamide and vitamin A are altered if given together. Do not use with mistletoe. Do not give with *Astragalus membranaceus* (Beg Kei, Buck Qi, Huang Chi, Milk Vetch, Yellow Leader); may decrease effects of chemotherapy

Lab: Suppresses positive reaction to uric acid, purified protein derivative, mumps, Candida; Papanicolaou test (Pap smear) may cause a false-positive result

Pharmacokinetics

Absorption: PO: Well absorbed

Distribution: PB: <60%

Metabolism: $t_{1/2}$: 3-12 h

Excretion: 25%-40% in urine unchanged; 5%-20% in feces

Nadir: 7-14 d

Pharmacodynamics

PO/IV: Onset: 7 d

Peak: 10-14 d

Duration: 21 d

Therapeutic Effects/Uses

Breast, lung, ovarian cancers; leukemias; lymphomas, multiple myeloma. An immunosuppressant agent

Mode of Action: Inhibition of protein synthesis through interference with DNA replication by alkylation of DNA

Side Effects

Nausea, vomiting, diarrhea, weight loss, hematuria, alopecia, impotence, sterility, ovarian fibrosis, headache, dizziness, dermatitis

Adverse Reactions

Hemorrhagic cystitis, secondary neoplasm, myelosuppression

Life-threatening: Leukopenia, thrombocytopenia, cardiotoxicity (very high doses), hepatotoxicity (long-term)

A, Adult; *C,* child; *d,* day; *DNA,* deoxyribonucleic acid; *h,* hour; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; $t_{1/2}$, half-life.

Note: Chemotherapy drug doses are based on body weight and prescribed either as milligrams per kilogram (mg/kg) or milligrams per meter squared (mg/m^2). Doses will also vary based on drug protocol, type and stage of cancer, age, functional status, and comorbid conditions (e.g., heart disease).

Nursing Process
Patient-Centered Collaborative Care

Alkylating Drugs: Cyclophosphamide

Assessment

- Conduct a detailed medication history, including a list of all concurrent medications, including prescriptions, over-the counter medicines, antacids, dietary supplements, vitamins, and herbal supplements to avoid drug-drug interactions.
- Obtain baseline information about patient's physical status. This should include height, weight, vital signs, laboratory values (complete blood count [CBC], uric acid, electrolytes, hepatic and renal studies, cardiopulmonary assessment, intake and output, skin assessment, daily activities status (i.e., ability to perform activities of daily living [ADLs], sleep-rest cycle), nutritional status, presence or absence of underlying symptoms of disease, and the use of current or past medication and treatment.
- Assess laboratory value at the beginning of therapy and at specified time intervals (ranging from weekly to monthly) during therapy. Drug may be withheld if red blood cell, white blood cell, or platelet counts drop below predetermined levels.
- Assess results of pulmonary function tests, chest radiographs, and renal and liver function studies during therapy.
- Assess temperature; a 1- or 2-degree change in temperature may be a sign of infection.

- Monitor for adequate intake and output.
- Obtain baseline data regarding patient's psychosocial status, including educational level, ability and desire to learn, support systems, past coping strategies, presence or absence of emotional difficulties, and self-care abilities.
- Assess patient and family knowledge related to therapeutic regimen.

Nursing Diagnoses

- Risk for infection related to side effects of cancer chemotherapy treatments and disease condition
- Risk for imbalanced nutrition, less than body requirements, related to GI side effects of chemotherapy
- Impaired urinary elimination related to hemorrhagic cystitis caused by chemotherapy
- Risk for bleeding related to effects of chemotherapy on the lining of the bladder and/or bone marrow suppression
- Deficient knowledge related to chemotherapeutic protocol
- Sexual dysfunction related to interference with normal menstrual cycle (in women) or lack of sperm production (in men)
- Disturbed body image related to cancer treatment
- Anxiety related to cancer diagnosis and unknown treatment outcomes
- Risk for caregiver role strain related to cancer diagnosis, treatment, and care responsibilities

Planning

- Patient's white blood cell, red blood cell, and platelet counts will be in the desired range.
- Patient will remain free from infection.
- Patient will maintain nutritional status (adequate fluid intake and output, sufficient caloric intake, stable weight).
- Patient will maintain adequate urinary output.
- Patient will remain free from symptoms of hemorrhagic cystitis.
- Patient/family/caregiver will demonstrate understanding of chemotherapeutic protocol (e.g., dose, administration).
- Potential body image disturbances will be discussed before therapy.
- Patient/family/caregiver will verbalize an understanding of the importance of reporting chemotherapy-related side effects and adverse reactions.
- Patient and family will verbalize strategies to minimize risks related to chemotherapy
- Patient's side effects will be managed to a level that the patient can tolerate and are not life-threatening.

Nursing Interventions

- Encourage patient to drink at least 2 L of fluid per day to promote excretion of cellular breakdown products and reduce the risk of hemorrhagic cystitis. Assess need for IV hydration.
- Hydrate patient with IV and/or oral fluids before chemotherapy is administered.
- Assess for signs and symptoms of hematuria, urinary frequency, or dysuria. Teach patient to empty bladder every 2 to 3 hours.
- Monitor blood urea nitrogen (BUN) and creatinine prior to administration and throughout duration of treatment.
- Handle drug with care during preparation and administration; avoid direct skin, eye, and mucus membrane contact with anticancer drugs. Follow protocols.
- Monitor IV site frequently for irritation and phlebitis.
- Administer prescribed premedications (30 to 60 minutes before giving drug).
- Monitor fluid intake and output and nutritional intake.
- Follow institution guidelines for safe handling, preparing, administering, and dispensing of chemotherapeutic agents.
- Maintain strict medical asepsis during dressing changes and invasive procedures.

Patient Teaching

General

- Teach patient to take cyclophosphamide early in the day to prevent accumulation of drug in the bladder during the night.
- Remind patient to consult with health care provider before administration of any vaccines.
- Advise patient to promptly report signs of infection (e.g., elevated temperature, fever, chills, sore throat, frequency and/or burning on urination, redness/swelling/pain near a wound); bleeding (e.g., bleeding gums, petechiae, bruises, hematuria, blood in the stool); and anemia (e.g., increased fatigue, dyspnea, orthostatic hypotension).
- Advise patient not to visit anyone who has a respiratory infection. A decreased WBC count puts patient at high risk for acquiring an infection.
- Emphasize protective precautions as necessary (e.g., hand washing, personal hygiene).
- Explain to patient and family the rationale for chemotherapy.
- Advise breastfeeding patient that cyclophosphamide is excreted in breast milk. Advise male patient that testicular atrophy and reversible oligospermia/azoospermia may occur.
- Teach importance of using birth-control measures as appropriate. Discuss sperm banking with male patients as appropriate.
- Advise patients of childbearing age to use contraceptives during therapy and for 2 years after completion of therapy.
- Provide information on where to purchase cosmetic supplies (e.g., wigs) should hair loss occur.

Side Effects

- Advise patient about good oral hygiene with a soft toothbrush for stomatitis; have patient use a soft toothbrush when platelet count is $<50{,}000/mm^3$.
- Remind premenopausal women that they may experience amenorrhea, menstrual irregularities, or sterility; advise male patients that they may experience impotence.
- Advise patient of possible hair loss; recommend a wig, hairpiece, scarf, or turban.
- Assess for use of alternative/complementary therapy that may interact with chemotherapy agent.

Diet

- Advise patient to follow a diet low in purines (e.g., organ meats, beans, peas) to alkalize urine.
- Advise patient to avoid citric acid.
- Offer patient food and fluids that may decrease nausea (e.g., cola, crackers, ginger ale).
- Plan small, frequent meals.

Cultural Considerations

- In some cultural groups, health care decisions are made by consensus, and the family plays a key role in filtering the information given to a patient. Issues related to informed consent and full disclosure of medical information may cause distress in cultural groups who place the needs of the family above the needs of the individual. Interactions should be modified based on family structure, religious values and beliefs, time orientation, cultural health practices, and verbal and nonverbal communication.
- Cultural assessment tools can provide general guidelines for health care providers.
- Hyperpigmentation of the tongue and oral mucosa after administration has been reported in African Americans. Incidence rate of high-grade neutropenia may be higher in Asian patients.

Evaluation

- Patient is free from infection.
- Patient maintains target weight.
- Patient maintains nutritional status.
- Patient does not develop hemorrhagic cystitis.
- Patient/family/caregiver education needs are met.
- Questions related to sexuality are answered.

ANTIMETABOLITES

Antimetabolites resemble natural metabolites that synthesize, recycle, and break down organic compounds for use by the body. However, antimetabolites disrupt metabolic processes and can inhibit enzyme synthesis. They are classified as CCS and exert their effects in the S phase (DNA synthesis and metabolism) of the cell cycle. This group is classified according to the substances with which they interfere; they include folic acid (folate) antagonists (e.g., methotrexate [Rheumatrex, Trexall], pemetrexed [Altima]), pyrimidine antagonists (e.g., fluorouracil [Adrucil]), purine antagonists (e.g., 6-mercaptopurine [Purinethol]), adenosine deaminase inhibitors (e.g., fludarabine [Fludara]), and ribonucleotide reductase inhibitors (e.g., hydroxyurea (Hydrea), 2-deoxycoformycin (pentostatin [Nipent]).

Antimetabolites are used to treat acute and chronic leukemia, myelodysplastic syndrome (MDS), breast cancer, head and neck cancer, lung cancer, osteosarcoma, and lymphomas. Two drugs in this classification, fluorouracil, also known as 5-FU [Adrucil]), and floxuridine (FUDR) are considered CCNS as well as CCS.

Methotrexate, also designated as *MTX* (Rheumatrex, Trexall), a folic acid antagonist, is used for the treatment of both cancerous and noncancerous (e.g., rheumatoid arthritis, psoriasis) conditions. Methotrexate is also used to induce miscarriage in patients with ectopic pregnancies. Methotrexate acts as a substitute for folic acid, which is needed for the synthesis of proteins and DNA. Cancer patients receiving high doses of MTX must be given leucovorin calcium to "rescue" **(leucovorin rescue)** normal cells from the adverse effects of the drug.

Numerous drug interactions may occur with MTX. Protein-bound drugs (e.g., aspirin, phenytoin) increase the toxicity of MTX. Nonsteroidal antiinflammatory drugs (NSAIDs) increase and prolong MTX levels. Cotrimoxazole (Bactrim) and pyrimethamine (Daraprim) increase MTX levels. Patients who are taking penicillins, cyclooxygenase 2 (COX-2) inhibitors, and OTC herbs should share this information with their physician, because these products interact with MTX. Table 37-4 lists the antimetabolite drugs, uses, and considerations.

The general side effects of antimetabolite drugs include bone marrow suppression (anemia, leukopenia, thrombocytopenia), stomatitis (inflammation of the oral mucosa), nausea, vomiting, alopecia, and hepatic and renal dysfunction. Major dose-limiting toxicities may occur in the hematopoietic and gastrointestinal systems. General adverse reactions to chemotherapeutic drugs are listed in Table 37-2.

Fluorouracil

Fluorouracil (5-FU, Adrucil) is a mainstay of treatment for a variety of cancers, including those of the breast, stomach, liver, pancreas, and skin.

SAFETY: Preventing Medication Errors

Do not confuse …

- **fluorouracil** with **flucytosine**

Pharmacokinetics Fluorouracil is administered IV to treat solid tumors and topically for superficial basal cell carcinoma. Less than 10% is bound to protein, and the half-life for the IV route is 10 to 20 minutes.

TABLE 37-4 ANTINEOPLASTICS: ANTIMETABOLITES

DRUG TYPE AND NAME	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Folic Acid Antagonists		
methotrexate (MTX)	IV: low dose: 10-50 mg/m^2; medium dose: 100-500 mg/m^2; high dose: 500 mg/m^2 (and higher followed by leucovorin rescue) IT: 10-15 mg/m^2 IM: 25 mg/m^2	Solid tumors, sarcomas, choriocarcinoma, leukemia. At higher doses, patients should be well hydrated; keep urine pH at 7.0 for drug solubility for excretion. Higher doses require use of leucovorin as a rescue for normal cells. Pregnancy category: D; PB: 50%; t½: 8-15 h
pemetrexed disodium (Alimta)	IV: 500 mg/m^2 day 1 of every 21-d cycle	A multitargeted antifolate to treat mesothelioma and non– small-cell lung cancer. Pregnancy category: D; PB: 81%; t½: 3.5 h
trimetrexate glucuronate (Neutrexin)	IV: 45 mg/m^2/d; infuse over 60-90 min for 21 d	Alternative drug therapy for *Pneumocystis carinii* pneumonia; treatment for patients with AIDS. May be used for colorectal cancer. Monitor CBC. Pregnancy category: D; PB: 86%-94%; t½: 11-13 h
Pyrimidine Analogues		
azacitidine (Vidaza)	SubQ: 75 mg/m^2 IV: 75-100 mg/m^2/d for 7 d, repeated every 4 wk	Treatment of chronic myelomonocytic leukemia. Pregnancy category: D; PB: UK; t½: 41 min
capecitabine (Xeloda)	PO: 2500 mg/m^2/d in two divided doses for 2 wk	Solid tumors, sarcomas, choriocarcinoma, leukemia. At higher doses, patients should be well hydrated; keep urine pH at 7.0 for drug solubility for excretion. Pregnancy category: D; PB: 50%; t½: 8-16 h
cytarabine (Cytosar-U, ARA-C, cytosine arabinoside)	For leukemia IV: 100 mg/m^2/d continuous infusion for 5-10 d For head and neck cancer: 1 mg/kg every 12 h for 5-7 d IV or subQ For bone marrow transplant 1.5 mg/m^2 continuous infusion for 48 h IT: 5-75 mg/m^2 every 2-7 d	Acute leukemias and lymphomas. Also used as an immunosuppressive drug after organ transplant. May be used in combination with other anticancer drugs. Nausea, vomiting, leukopenia, and thrombocytopenia are common side effects. Pregnancy category: D; PB: 15%; t½: 1-3 h
floxuridine (FUDR)	Intra-arterial (hepatic): 0.1-0.6 mg/kg/d for 7-14 d. Delivered by slow infusion pump	Metastatic colon cancer and hepatomas. Pregnancy category: D; PB: UK; t½: 20 h
5-fluorouracil (5-FU, Adrucil)	See Prototype Drug Chart 37-2.	
gemcitabine HCl (Gemzar)	For breast cancer: IV: 1250 mg/m^2 over 30 min days 1 and 8 of 21-d cycle For pancreatic cancer: IV: 1000 mg/m^2 over 30 min weekly for up to 7 wk For NSCL: IV: 1000 mg/m^2 over 30 min days 1 and 8 and 15 For ovarian cancer: IV: 1000 mg/m^2 over 30 min days 1 and 8 of 21-d cycle	Advanced or metastatic adenocarcinoma of the pancreas, non–small-cell lung cancer and bladder cancer. Acts at S phase of cell cycle. Monitor leukocytes and platelet count; reduce dose if values are extremely low. Pregnancy category: D; PB: UK; t½: 1-10 h
nelarabine (Arranon)	A: 1500 mg/m^2 IV over 2 hours on days 1, 3, and 5; repeat every 3 wk C: 650 mg/m^2 IV over 1 h on days 1, 2, 3, 4, 5; repeat every 3 wk	Treatment of refractory or relapsed T-cell lymphoblastic leukemia and T-cell lymphoblastic lymphoma. Pregnancy category: D; PB: <25%; t½: 30 min-3 h
Purine Analogues		
cladribine (Leustatin)	IV: 0.09 mg/kg/d as a continuous infusion for 7 d	For treatment of hairy cell leukemia and chronic lymphocytic leukemia. Adverse reactions: bone marrow suppression, fever, nausea, vomiting, diaphoresis. Pregnancy category: D; PB: 20%; t½: 5.4 h
clofarabine (Clolar)	IV: 52 mg/m^2 IV over 2 h daily for 5 d	To treat refractory or relapsed acute lymphoblastic leukemia in children. Pregnancy category: D; PB: 47%; t½: 105 min

TABLE 37-4 ANTINEOPLASTICS: ANTIMETABOLITES—cont'd

DRUG TYPE AND NAME	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
fludarabine (Fludara)	PO: 40 mg/m^2/d for 5 d; repeat every 28 d IV: 25 mg/m^2; infuse over 30 min daily for 5 d; repeat every 28 d	Chronic lymphocytic leukemia in patients who have not responded to other alkylating drugs; low-grade non-Hodgkin's lymphoma. Anorexia, nausea, diarrhea, fever, and peripheral edema may occur. Pregnancy category: D; PB: UK; t½: 9 h
6-mercaptopurine (Purinethol)	PO: Induction dose 2.5 mg/kg/d followed by maintenance dose	First used in 1952 for treating acute lymphatic leukemia. Also used as immunosuppressive drug. Adverse reactions include hepatotoxicity, bone marrow suppression, hyperuricemia. Pregnancy category: D; PB: 19%; t½: 45 min
thioguanine (6-thioguanine, Lanvis)	PO: A: 100 mg/m^2 every 12 h for 5-10 d C: 100 mg/m^2 every 12 h for 5-10 d OR 1-3 mg/kg/d	Acute and chronic myelogenous leukemia. Long duration of action. Pregnancy category: D; PB: UK; t½: 2-11 h
Ribonucleotide Reductase Inhibitors (Enzyme Inhibitors)		
hydroxyurea (Hydrea)	PO: 20-30 mg/kg/d	Melanoma, resistant chronic myelocytic leukemia, and ovarian cancer. Long duration of action. Pregnancy category: D; PB: UK; t½: 3-4 h
pentostatin (Nipent)	IV: 4 mg/m^2 every other wk	Hairy cell leukemia refractory to alpha-interferon. Very long duration of action. Pregnancy category: D; PB: UK; t½: 6 h

Note: Chemotherapeutic doses and schedules will vary depending on protocol, body surface area (m^2), age, functional status, and comorbid conditions. For a full discussion of body surface area in dosage calculation, see Chapter 14.

AIDS, Acquired immunodeficiency syndrome; *CBC,* complete blood cell count; *h,* hour; *min,* minute; *PB,* protein-binding; *t½,* half-life; *UK,* unknown; *wk,* week.

A small amount of the drug is excreted in the urine, and up to 80% is excreted by the lungs as carbon dioxide.

Pharmacodynamics Fluorouracil blocks the enzyme action necessary for DNA and ribonucleic acid (RNA) synthesis. The drug has a low therapeutic index and is used alone or in combination with other anticancer drugs. Fluorouracil can cross the blood-brain barrier. Its duration of action is 30 days.

HERBAL ALERT 37-2

5-Fluorouracil

- Use cautiously with ginseng and St. John's wort (may interfere with chemotherapy). *Do not use with mistletoe because it may promote cancer growth.*
- Astragalus stimulates the immune system and may help speed recovery from immunosuppressive chemotherapy. Astragalus has blood clot–fighting properties and may increase risk of bleeding when given with 5-FU.

Side Effects and Adverse Reactions

The side effects of 5-FU (Adrucil) are similar to other anticancer drugs. These include anorexia, nausea, vomiting, diarrhea, stomatitis, alopecia, photosensitivity, increased skin pigmentation, rash, and erythema. Stomatitis is an early sign of toxicity and should be reported to the physician. Myelosuppression may occur 4 to 8 days after the beginning of drug therapy.

Prototype Drug Chart 37-2 presents the pharmacologic data for 5-FU.

Nursing Process

Patient-Centered Collaborative Care

Antimetabolites: Fluorouracil

Assessment

- Conduct a detailed medication history, including a list of all concurrent medications, including prescriptions, over-the counter medicines, antacids, dietary supplements, vitamins, and herbal supplements to avoid drug-drug interactions.
- Obtain baseline information about patient's physical status. This should include height, weight, vital signs, laboratory values (CBC, uric acid, electrolytes, hepatic and renal studies, cardiopulmonary assessment, intake and output, skin assessment, daily activities status [i.e., ability to perform ADLs], sleep-rest cycle), nutritional status, presence or absence of underlying symptoms of disease, and use of current or past medication and treatment.
- Assess laboratory values at the beginning of therapy and at specified time intervals (ranging from weekly to monthly) during therapy. Drug may be withheld if red blood cell, white blood cell, or platelet counts drop below predetermined levels.
- Assess renal function studies before and during drug therapy.
- Assess temperature; fever may be an early sign of infection.
- Obtain baseline data regarding patient's psychosocial status, including educational level, ability and desire to

PROTOTYPE DRUG CHART 37-2

Fluorouracil, 5-Fluorouracil, 5-FU

Drug Class

Antimetabolite
Trade Names: Adrucil, 5-FU,Fluroplex, Efudex (topical)
Pregnancy Category: D/X (topical)

Dosage

A: IV: 12 mg/kg/d × 4 d; *max:* 800 mg/d; repeat with 6 mg/kg on days 6, 8, 10, and 12 or as indicated. Dose regimens are varied.
Topical: 1%-2% sol/cream b.i.d. to head/neck lesions; 5% to other body areas

Contraindications

Hypersensitivity, pregnancy, severe infection, myelosuppression, marginal nutritional status. Reduce dose in patients with impaired hepatic or renal function or those with malnutrition.

Drug-Lab-Food Interactions

Drug: Bone marrow depressants increase chances of toxicity. Avoid live virus vaccines, which may potentiate virus replication. Increased 5-FU toxicity with concomitant use of leucovorin calcium. Metronidazole may increase 5-FU toxicity (clearance of 5-FU decreased). Increased pharmacologic effects of 5-FU when given with cimetidine (Tagamet). Thiazide diuretics increase myelosuppression.
Lab: May decrease albumin; may increase excretion of 5-HIAA in urine
Herb: Use cautiously with ginseng, St. John's wort, and gingko biloba. Do not use with mistletoe. Topical peppermint oil and eucalyptus oil may increase absorption of topical 5-FU. Avoid simultaneous use.

Pharmacokinetics

Absorption: IV and topical: 5%-10%
Distribution: PB: UK
Metabolism: t ½: 10-20 min
Excretion: In urine and expired carbon dioxide
Nadir: 10-14 d

Pharmacodynamics

Effects on blood count:
Peak: 10-14 d
IV: Onset: 1-9 d
Peak: 9-21 d
Duration: 30 d
Topical: Onset: 2-3 d
Peak: 2-6 wk
Duration: 4-8 wk

Therapeutic Effects/Uses

Breast, colorectal, pancreas, stomach, esophageal, and head and neck cancers. Given in combination with levamisole after surgical resection in patients with Duke's stage C colon cancer
Mode of Action: Prevention of thymidine synthetase production, thereby inhibiting DNA and RNA synthesis; not phase specific

Side Effects

Stomatitis, nausea, vomiting, diarrhea, alopecia, rash, photosensitivity. Diarrhea may be severe.

Adverse Reactions

Bone marrow suppression
Life-threatening: Thrombocytopenia, myelosuppression, hemorrhage, renal failure

5-FU, Fluorouracil; *5-HIAA,* 5-hydroxyindoleacetic acid; *A,* adult; *b.i.d.,* twice a day; *d,* day; DNA, deoxyribonucleic acid; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein-binding; *RNA,* ribonucleic acid; *sol,* solution; *t ½,* half-life; *UK,* unknown; *wk,* week.

learn, support systems, past coping strategies, presence or absence of emotional difficulties, and self-care abilities.

- Assess patient and family knowledge related to therapeutic regimen.

Nursing Diagnoses

- Risk for infection related to bone marrow suppression
- Risk for imbalanced nutrition, less than body requirements, related to GI side effects of chemotherapy
- Acute pain related to GI side effects (mucositis/stomatitis) of chemotherapy
- Risk for impaired skin integrity related to photosensitivity caused by chemotherapy
- Risk for impaired perianal skin integrity related to diarrhea caused by chemotherapy
- Deficient knowledge related to chemotherapeutic protocol
- Risk for caregiver role strain related to cancer diagnosis, treatment, and care responsibilities

Planning

- Patient blood counts will remain in the desired range.
- Patient will maintain nutritional status (adequate fluid intake and output, adequate caloric intake, stable weight).
- Patient will have adequate pain control.
- Patient will limit exposure to sunlight.

- Patient will not experience perianal skin breakdown.
- Patient/family/caregiver will demonstrate understanding of chemotherapeutic protocol (dose, administration, side effects, and adverse reactions).

Nursing Interventions

- Monitor IV site frequently. Extravasation produces severe pain. If this occurs, apply ice pack and notify health care provider.
- Handle drug with care during preparation and administration; avoid direct skin contact with anticancer drugs. Follow protocols.
- Administer antiemetic 30 to 60 minutes before drug to prevent vomiting.
- Monitor fluid intake and output and nutritional intake. GI effects are common.
- Assess for hyperpigmentation along the vein in which 5-FU was administered.
- Maintain strict medical asepsis during dressing changes and invasive procedures.
- Monitor blood counts and laboratory values.
- Offer patient food and fluids that may decrease nausea (e.g., crackers, cola, ginger ale).
- Encourage mouth rinses every 2 hours with normal saline.
- Plan small, frequent meals.
- Support good oral hygiene; brush teeth with soft toothbrush, and use waxed dental floss.
- Record number and consistency of stools; monitor perineal skin condition.
- Develop patient/family teaching plan on signs and symptoms of photosensitivity.

Patient Teaching

General

- Advise patient to promptly report signs of infection (e.g., fever, sore throat, chills, urinary frequency; burning on urination; redness, swelling, or pain near a wound); bleeding (e.g., bleeding gums, petechiae, bruises, hematuria, blood in the stool); or signs of anemia (e.g., increased fatigue, dyspnea, orthostatic hypotension).
- Teach patient to examine mouth daily and report signs of stomatitis (soreness, ulcerations, white patches in mouth). Oral hygiene several times a day is essential. If stomatitis occurs, rinse mouth with baking soda or normal saline. Use a soft toothbrush.
- Advise patient not to visit anyone who has a respiratory infection. A decreased white blood cell (WBC) count puts patient at risk for acquiring an infection.
- Advise patient to take year-round photosensitivity precautions. Use sunscreen when outdoors.
- Emphasize protective precautions as necessary (e.g., hand washing, personal hygiene).
- Advise patient to take pain medication as prescribed to relieve mouth pain related to mucositis/stomatitis.
- Teach importance of using birth-control measures as appropriate. Discuss sperm banking with male patients as appropriate.
- Teach patient to avoid pregnancy for 3 to 4 months after completing antineoplastic therapy in most situations. Some sources recommend that both men and women avoid conception for 2 years after completion of treatment.

Side Effects

- Advise patient about good oral hygiene with a soft toothbrush for mucositis/stomatitis; have patient use a soft toothbrush when platelet count is $\leq 50{,}000/mm^3$. Instruct patient to rinse mouth every 2 hours with normal saline and avoid use of commercial mouthwashes that contain alcohol.
- Remind premenopausal women that they may experience amenorrhea, menstrual irregularities, or sterility. Advise male patients that they may experience impotence.
- Advise patient of possible hair loss; recommend a wig, hairpiece, scarf, or turban.
- Assess for use of alternative/complementary therapy that may interact with chemotherapy.

Diet

- Encourage small frequent meals.
- Encourage use of cool, bland foods.
- Offer ice chips or ice pops to help relieve mouth pain.

Cultural Considerations

- In some cultural groups, health care decisions are made by consensus, and the family plays a key role in filtering information given to the patient. Issues related to informed consent and full disclosure of medical information may cause distress in cultural groups who place the needs of the family above the needs of the individual. Interactions should be modified based on family structure, religious values and beliefs, time orientation, cultural health practices, and verbal and nonverbal communication.
- Cultural assessment tools can provide general guidelines for health care providers.
- An increased incidence of hyperpigmentation has been reported in dark-skinned people. Hyperpigmentation may be seen on the skin, nails, hair, and oral mucosa. This usually disappears over time.

Evaluation

- Patient is free from infection.
- Oral mucosa is free from erythema and swelling.
- Pain is controlled.
- Skin integrity remains intact.
- Patient/family/caregiver education needs are met.
- Questions regarding sexuality are answered.

TABLE 37-5 ANTINEOPLASTICS: ANTITUMOR ANTIBIOTICS

DRUG TYPE AND NAME	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
bleomycin (Blenoxane)	5-20 units/m^2 once a wk or 10-20 units/m^2 twice a wk IV: continuous 15 units/m^2/d for 4 d Intracavitary: Pleural space 50-60 units in 50-100 mL diluent	Squamous cell carcinomas, testicular tumor (when used with vinblastine and cisplatin), and lymphomas. Low incidence of bone marrow suppression. Lifetime dose is 400 units/m^2. A serious adverse reaction is anaphylaxis. Long duration of action. Pregnancy category: D; PB: 1%; t½: 2-5 h
dactinomycin (Actinomycin D, Cosmegen)	IV: 10-15 mcg/kg/d for 5 d (every 3-4 wk) Dose varies depending on indication	Testicular tumors, Wilms' tumor, choriocarcinoma, and rhabdomyosarcoma. Nausea and vomiting may occur during first 24 h. Long duration of action. Pregnancy category: C; PB: 80%-90%; t½: 36 h
daunorubicin HCl (Cerubidine)	IV: 30-60 mg/m^2/d for 3 d	Leukemia, Ewing's sarcoma, Wilms' tumor, neuroblastoma, and non-Hodgkin's lymphoma. Long duration of action. Pregnancy category: D; PB: 80%; t½: 19 h
doxorubicin (Adriamycin)	See Prototype Drug Chart 37-3.	
epirubicin (Ellence)	IV: 100-120 mg/m^2 every 3-4 wk	Cancers of breast, lung, lymph system, stomach, and ovaries. Metastatic node-positive breast cancer; adjuvant with anticancer therapy. May be used in combination therapy with cyclophosphamide and fluorouracil (CEF) for breast cancer; improved survival rate over cyclophosphamide, methotrexate, and fluorouracil (CMF). Adverse effects include bone marrow suppression, cardiotoxicity (less than doxorubicin), and extravasation necrosis. Less cardiotoxic than doxorubicin; similar efficacy. Pregnancy category: D; PB: 77%; t½: 33 h
idarubicin (Idamycin)	IV: Induction: 12 mg/m^2 slow IV push for 3 d	Acute monocytic leukemia and solid tumors. More potent than daunorubicin or doxorubicin. Vesicant, monitor CBC. Urine may be red. Pregnancy category: D; PB: 97%; t½: 22 h
mitomycin (Mutamycin)	IV: 10 mg/m^2 every 8 wk Intracavitary: Bladder: 20-40 mg in 20-40 mL of water	Disseminated adenocarcinoma of breast, stomach, and pancreas. Also used for cancer of the head, neck, cervix, and lung. Monitor temperature and CBC. Pregnancy category: D; PB: UK; t½: 12 min
mitoxantrone (Novantrone)	IV: For acute leukemia: Induction: 12 mg/m^2/d for 3 d	Acute nonlymphocytic leukemia; may be used for breast cancer. Rash, dyspnea, hypotension, facial swelling, blue urine, sclera, skin hue change may occur. Severe hepatic dysfunction with decreased total body clearance. Pregnancy category: D; PB: 95%; t½: 1.5-13 d
valrubicin (Valstar)	Intravesicular: Bladder: 800 mg (in 75 mL diluent) every wk for 6 wk	Bladder cancer. May cause urinary frequency and urgency, dysuria, hematuria, and bladder pain. Pregnancy category: UK; PB: >99%; t½: UK

Note: Chemotherapeutic doses and schedules will vary depending on protocol, body surface area (m^2), age, functional status, and comorbid conditions. For a full discussion of body surface area in dosage calculation, see Chapter 14.

CBC, Complete blood cell count; *d,* day; *h,* hour; *min,* minute; *PB,* protein-binding; *t½,* half-life; *UK,* unknown; *wk,* week.

ANTITUMOR ANTIBIOTICS

Antitumor antibiotics (bleomycin [Blenoxane], dactinomycin (actinomycin-D) [Cosmegen], daunorubicin [Cerubidine, Daunomycin], doxorubicin [Adriamycin], mitomycin [Mutamycin], Mitoxantrone [Novantrone]) inhibit protein and RNA synthesis and bind DNA, causing fragmentation. There are several types of antitumor antibiotics, including the anthracyclines and miscellaneous drugs. Except for bleomycin, which has its major effect on the G2 phase, they are classified as CCNS drugs. These antitumor antibiotics differ from one another and are used for various cancers, including leukemia and many solid tumors. Table 37-5 lists the antitumor antibiotics, uses, and considerations.

Adverse reactions to the antitumor antibiotics are similar to other antineoplastics and include alopecia, nausea, vomiting, stomatitis, and myelosuppression. Antitumor antibiotics are capable of causing **vesication** (blistering of tissue); exceptions to this are bleomycin (Blenoxane) and plicamycin (Mithracin). General adverse reactions to chemotherapeutic drugs are listed in Table 37-2.

Doxorubicin

Doxorubicin is used in the treatment of many types of cancer and is an important prototype drug that has led to the development of many analogs (e.g., epirubicin [Ellence], idarubicin [Idamycin]). However, it has severe cardiotoxic side effects and must be given with caution.

HERBAL ALERT 37-3

Doxorubicin

- Green tea *(Camellia sinensis)* may enhance antitumor effects of doxorubicin. Report use to the health care provider. Use cautiously with grapeseed (inhibits effects of doxorubicin), garlic (anticlotting properties, may decrease effects of chemotherapy), and St. John's wort (may decrease effectiveness of chemotherapy).
- Schisandra extract (Schisandra, gomishi, Sheng-Mai-San) may decrease the cardiotoxicity associated with doxorubicin. Schisandra stimulates hepatic metabolism and may interfere with doxorubicin, which is excreted through the liver.

Pharmacokinetics Doxorubicin is administered IV and metabolized in the liver to active and inactive metabolites. The various metabolites affect the half-life; the initial phase of doxorubicin is 12 minutes, the intermediate phase is 3.5 hours, and the final phase is 30 hours.

SAFETY: Preventing Medication Errors

Do not confuse …

- **doxorubicin** (Adriamycin) with **idarubicin** (Idamycin)

Pharmacodynamics Doxorubicin) is prescribed in combination with other anticancer agents for the treatment of cancers of the breast, ovaries, lung, and bladder and also for leukemias and lymphomas. A major concern for clinicians is that doxorubicin can cause cardiotoxicity. Recipients of this drug are limited to a maximum lifetime dose of 550 mg/m^2. This dose may be lower for individuals who have preexisting cardiac problems, use other cardiotoxic medications, are older, or have received radiation to the chest. Prior to treatment with doxorubicin, the cardiac function of potential recipients is assessed. Dexrazoxane (Zinecard) is a cytoprotective (chemoprotective) agent that may be given to help prevent cardiotoxicity associated with doxorubicin administration.

Side Effects and Adverse Reactions

Some antitumor antibiotics can cause organ toxicities. Individuals receiving bleomycin (Blenoxane) may develop pneumonitis that progresses to pulmonary fibrosis. In addition to doxorubicin, daunorubicin (Cerubidine) and idarubicin (Idamycin) can also cause cardiotoxicity.

Prototype Drug Chart 37-3 presents the pharmacologic data for doxorubicin.

PROTOTYPE DRUG CHART 37-3

Doxorubicin

Drug Class

Antitumor antibiotic

Trade Name: Adriamycin

Pregnancy Category: D

Dosage

A: 40-75 mg/m^2 as a single dose every 3-4 wk or no more than 30 mg/m^2 every 2 wk with 1- wk rest

IV for 3 d every 4 wk

Safety and efficacy have not been established for children.

Reduce dose with renal and hepatic impairment.

Contraindications

Pregnancy, severe cardiac disease. Cardiac status and cardiac ejection fraction should be tested before starting doxorubicin therapy. Do not exceed a lifetime cumulative dose of 550 mg/m^2 (450 mg/m^2 if patient has had prior chest irradiation or is receiving cyclophosphamide). Dexrazoxane (Zinecard) is used to help prevent or lessen cardiac damage.

Caution: Hepatic and renal impairment

Drug-Lab-Food Interactions

Drug: Calcium channel blockers, paclitaxel (Taxol), and mitomycin increase risk of cardiotoxicity if given with doxorubicin. Doxorubicin may decrease digoxin levels. Doxorubicin decreases levels of phenytoin. Cyclophosphamide (Cytoxan) increases risk of cardiotoxicity and hemorrhage. Increased risk of hepatotoxicity when given with mercaptopurine. Increased plasma clearance of doxorubicin when given with barbiturates. Precipitate will form when doxorubicin is combined with heparin or 5-FU. Decreased metabolic clearance of 5-FU (Adrucil) and increased cytotoxicity when given with alfa interferon. Prolonged hemotoxic effects may occur if doxorubicin and cyclosporine are given together. Do not give with zidovudine (Retrovir), as it may decrease effectiveness of doxorubicin.

Lab: ECG changes. Increases uric acid.

Herb: Green tea may enhance antitumor effects. Report use to health care provider. Use cautiously with grapeseed, garlic, St. John's wort.

Pharmacokinetics

Absorption: IV

Distribution: PB: 80%-90%

Metabolism: t½: 3-30 h

Excretion: 40% in bile and 5% in urine

Nadir: 10-14 d (doxorubicin)

Pharmacodynamics

IV: Onset: 7-10 d

Peak: 14 d

Duration: 21 d

Therapeutic Effects/Uses

Breast, bladder, ovarian, and lung cancers; leukemias; lymphomas, soft-tissue and bone sarcoma

Mode of Action: Inhibits DNA and RNA synthesis; has immunosuppressant activity

Side Effects

Stomatitis, anorexia, nausea, vomiting, diarrhea, rash, alopecia. Doxorubicin is a potent vesicant. May cause a flare reaction. Nausea and vomiting are dose-related and may begin 1-3 h after administration. Causes discolored urine (pink to red) for up to 48 h. May cause "radiation recall" to previously irradiated skin.

Adverse Reactions

Esophagitis; anemia; hyperpigmentation of nails, tongue, and oral mucosa, especially in African Americans. Teratogenic, mutagenic, and carcinogenic.

Life-threatening: Thrombocytopenia, leukopenia, cardiotoxicity, congestive heart failure, electrocardiogram changes, severe myelosuppression, anaphylaxis

5-FU, Fluorouracil; *d,* day; *DNA,* deoxyribonucleic acid; *ECG,* electrocardiogram; *h,* hour; *IV,* intravenous; *PB,* protein-binding; *RNA,* ribonucleic acid; *t ½,* half-life; *wk,* week.

Nursing Process
Patient-Centered Collaborative Care

Antitumor Antibiotics: Doxorubicin

Assessment
- Conduct a detailed medication history, including a list of all concurrent medications, including prescriptions, over-the counter medicines, antacids, dietary supplements, vitamins, and herbal supplements to avoid drug-drug interactions.
- Obtain baseline information about patient's physical status. This should include height, weight, vital signs, laboratory values (CBC, uric acid, electrolytes, hepatic and renal studies, cardiopulmonary assessment, intake and output, skin assessment, daily activities status [i.e., ability to perform ADLs], sleep-rest cycle), nutritional status, presence or absence of underlying symptoms of disease, and the use of current or past medications and treatment.
- Assess laboratory tests at the beginning of therapy and at specified time intervals (ranging from weekly to monthly) during therapy. Drug may be withheld if red blood cell (RBC), white blood cell (WBC), or platelet counts drop below predetermined levels.
- Assess CBC, differential, and platelet count weekly. Drug may be withheld if RBC, WBC, or platelet counts drop below predetermined levels.
- Conduct thorough physical assessment, and document findings.
- Assess temperature; fever may be an early sign of infection.
- Obtain baseline data regarding patient's psychosocial status, including educational level, ability and desire to learn, support systems, past coping strategies, presence or absence of emotional difficulties, and self-care abilities.
- Assess patient's and family's knowledge related to therapeutic regimen.
- Assess plans for pregnancy (if appropriate).

Nursing Diagnoses
- Risk for infection related to bone marrow suppression
- Risk for decreased cardiac tissue perfusion related to cardiotoxic effects of chemotherapy
- Risk for impaired skin integrity related to vesicant properties of chemotherapy
- Deficient knowledge related to antineoplastic therapy
- Disturbed body image related to cancer treatment
- Anxiety related to cancer diagnosis and the unknown outcomes of treatment
- Risk for caregiver role strain related to cancer diagnosis, treatment, and care responsibilities

Planning
- Patient will maintain blood cell values in the desired range.
- Patient will be free from cardiac dysfunction.
- Patient's skin integrity will remain intact.
- Patient/family/caregiver will demonstrate understanding of the chemotherapy regimen, including side effects.
- Assess patient/family/caregiver knowledge related to chemotherapeutic protocol.
- Discuss potential body image disturbances prior to therapy.

Nursing Interventions
- Assess cardiac status.
- Monitor IV site frequently. Doxorubicin is a severe vesicant whose effects are not immediately apparent. Give drug through a large-bore, quickly running IV infusion. Monitor blood counts and laboratory values.
- Extravasation produces severe pain. If extravasation occurs, stop infusion immediately. Do not remove IV device from patient. Attempt to aspirate residual vesicant from IV device using a small syringe, and then remove the device. Assess the site. Notify health care provider. Apply warm packs for 15 to 20 minutes at least 4 times per day for first 24 hours. For peripheral extravasations, elevate extremity. Tissue necrosis may occur 3 to 4 weeks after infiltration into tissue.
- Handle drug with care during preparation; avoid direct skin contact with drug.
- Administer antiemetic 30 to 60 minutes before chemotherapy.
- Monitor for changes in urine color (pink to red). The drug is red and is excreted in the urine.
- Offer patient food and fluids that may decrease nausea (e.g., crackers, cola, ginger ale).
- Plan small, frequent meals.
- Administer prophylactic antibiotics to prevent infection.
- Offer analgesics for pain as prescribed.
- Maintain strict medical asepsis during dressing changes and invasive procedures.
- Support good oral hygiene. Use soft toothbrush. Use waxed dental floss.
- Monitor fluid intake and output and nutritional intake.

Patient Teaching
General
- Teach patient the signs and symptoms of cardiac dysfunction (shortness of breath, palpitations, edema in extremities) and to report these to health care provider.
- Teach patient about changes in urine color (pink or red) caused by this drug.
- Advise patient to promptly report signs of infection (e.g., fever, sore throat), bleeding (e.g., bleeding gums, petechiae, bruises, hematuria, blood in stool), and anemia (e.g., increased fatigue, dyspnea, orthostatic hypotension).

- Emphasize protective precautions (e.g., hand washing, personal hygiene).
- Teach patient that complete alopecia occurs with doses >50 mg/m^2. Teach that hair will begin to regrow within several months after therapy is completed.
- Teach patient about "radiation recall" on previously irradiated skin.
- Advise patient not to visit anyone who has a respiratory infection. A decreased WBC count puts patient at risk for acquiring an infection.
- Teach importance of using birth-control measures as appropriate. Discuss sperm banking with male patients as appropriate.
- Teach patient to avoid pregnancy for 3 to 4 months after completing antineoplastic therapy in most situations. Some sources recommend that both men and women avoid conception for 2 years after completion of treatment.
- Provide information on where to purchase cosmetic supplies (e.g., wigs) should hair loss occur.

Side Effects

- Assess for nausea/vomiting, and administer antiemetics as prescribed.
- Teach importance of using birth-control measures as appropriate. Discuss sperm banking with male patients as appropriate.
- Remind premenopausal women that they may experience amenorrhea, menstrual irregularities, or sterility; advise male patient that he may experience impotence.
- Advise patient of possible hair loss; recommend a wig, hairpiece, scarf, or turban.
- Assess for use of alternative/complementary therapies that may interact with chemotherapy agent.

Diet

- Encourage small, frequent meals.
- Encourage eating bland foods.
- Avoid foods with extreme temperatures.

Cultural Considerations

- In some cultural groups, health care decisions are made by consensus, and the family plays a key role in filtering information given to the patient. Issues related to informed consent and full disclosure of medical information may cause distress in cultural groups that place the needs of the family above the needs of the individual. Interactions should be modified based on family structure, religious values and beliefs, time orientation, cultural health practices, and verbal and nonverbal communication.
- Cultural assessment tools can provide general guidelines for health care providers.
- Hyperpigmentation of the tongue and oral mucosa has been seen after the administration of doxorubicin in African Americans. Incidence rate of high-grade neutropenia may be higher in Asian patients.

Evaluation

- Patient is free from infection.
- Cardiac function is maintained.
- Patient and family educational needs are met.
- Side effects of therapy are controlled.

PLANT ALKALOIDS

Plant alkaloids are derived from natural products that are CCS and block cell division at the M phase of the cell cycle. The **vinca alkaloids** (e.g., vinblastine [Velban], vincristine [Oncovin], and vinorelbine [Navelbine]) are obtained from the periwinkle plant. The antimicrotubules or **taxanes** group (e.g., docetaxel [Taxotere] and paclitaxel [Taxol]) were originally procured from the needles and bark of the yew tree, which only grows in the Pacific Northwest. Due to the scarcity of this natural resource, a semisynthetic form of paclitaxel was developed and then approved by the FDA. Docetaxel (Taxotere) is a semisynthetic analogue of paclitaxel. The podophyllotoxins (e.g., etoposide [VP-16, Pepesid], teniposide [VP26, Vumon]) and camptothecan analogues (e.g., Irinotecan [Camptosar, CPT-11], Topotecan [Hycamtin]) interfere with the action of topoisomerase enzymes, causing apoptosis in cancer cells. A few retinoid derivatives (e.g., bexarotene [Targretin], thalidomide [Thalomid]) play a limited role in treating cancer as well. Table 37-6 lists the plant alkaloids and their uses and considerations.

Adverse reactions to plant alkaloids include leukopenia, hypersensitivity reactions, partial-to-complete alopecia, constipation, nausea, vomiting, diarrhea, and phlebitis. The plant alkaloids damage peripheral nerve fibers and may cause reversible or irreversible neurotoxicity. Signs and symptoms of neurotoxicity include a decrease in muscular strength, numbness, tingling of fingers and toes ("stocking/glove" syndrome), constipation, and motor instability. Other adverse effects of these drugs include loss of deep tendon reflexes, muscle weakness, joint pain, and bone marrow suppression. Docetaxel may cause fluid retention. General adverse reactions to chemotherapeutic drugs are listed in Table 37-2.

Vincristine

Vincristine (Oncovin), developed from the periwinkle plant, was originally approved by the FDA in the 1960s to treat Wilms' tumor in children.

Pharmacokinetics Vincristine is given IV. Its half-life is between 19 and 155 hours, and it is primarily (~75%) protein-bound. The drug is extensively metabolized by the liver.

HERBAL ALERT 37-4

Vincristine

- Use cautiously with bromelain (an extract from the pineapple plant), which may improve the efficacy of vincristine. *Catharanthus roseus* (periwinkle) may increase risk of bone marrow suppression when given with vincristine. Schisandra extract (Schisandra, gomishi, Sheng-Mai-San) stimulates hepatic metabolism and may interfere with vincristine, which is excreted through the liver.

TABLE 37-6 ANTINEOPLASTICS: PLANT ALKALOIDS

DRUG TYPE AND NAME	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Vinca Alkaloids		
vinblastine (Velban)	IV: 1.5-2.0 mg/m^2/d continuous infusion for 5 d	Cancers of the testes, breast, and kidney and treatment of lymphomas, lymphosarcomas, and neuroblastomas. Nausea, vomiting, and alopecia are common side effects. Check CBC before dosing. Pregnancy category: D; PB: 75%; t½: 25 h
vincristine (Oncovin)	IV: 0.4-1.4 mg/m^2/wk	Cancer of the breast, lungs, and cervix; multiple myelomas, sarcomas, lymphomas, Wilms' tumor. Assess neurologic difficulties. Used for treating Hodgkin's disease in combination therapy, MOPP (mechlorethamine, vincristine, procarbazine, and prednisone). Do not give intrathecally. Pregnancy category: D; PB: 75%; t½: triphasic 2-85 h (see Prototype Drug Chart 37-4)
vinorelbine (Navelbine)	IV: 30 mg/m^2/wk	First-line treatment for ambulatory patients with advanced, unresectable non–small-cell lung cancer (NSCLC). May be used alone or in combination with cisplatin for stage IV NSCLC and in combination with cisplatin for stage III NSCLC. Pregnancy category: D; PB: UK; t½: 27-43 h
Antimicrotubules/Taxanes		
docetaxel (Taxotere)	IV: 60-100 mg/m^2 over 1-h infusion every 3 wk	Advanced or metastatic breast cancer. Inhibits mitosis in cells. Greater antitumor activity with lower toxicity effect than paclitaxel (Taxol). Monitor WBC and platelet count; if low, dose may need to be decreased. Pregnancy category: D; PB: UK; t½: 11 h
paclitaxel (Taxol)	IV: For breast cancer: 175 mg/m^2 over 3-h infusion every 3 wk For ovarian cancer: 135-175 mg/m^2 over 24-h infusion	Metastatic ovarian and breast cancer. Monitor vital signs and electrocardiogram. Long duration of action (3 wk). Peak action is 11 d. Pregnancy category: D; PB: 80%-90%; t½: 5-17 h
Podophyllotoxins		
etoposide (VP-16, Vepesid)	IV: For testicular cancer: 50-100 mg/m^2/d for 5 d For small-cell lung cancer 75-200 mg/m^2/d for 3 d	Testicular cancer, small-cell lung cancer. Give by slow IV infusion (30-60 min), as hypotension is a side effect of rapid infusion. Bone marrow suppression is a dose-limiting toxicity; Pregnancy category: D; PB: wide variation; t½: 6-12 h
teniposide (VM-26, Vumon)	IV: 100 mg/m^2/wk for 6-8 wk OR 50 mg/m^2 twice weekly for 4 wk	Acute lymphocytic leukemia, neuroblastoma, non-Hodgkin's lymphoma. Give by slow IV infusion (30-60 min), as hypotension is a side effect of rapid infusion. Pregnancy category: D; PB > 95%; t½: 5 h
Camptothecan Analogs		
irinotecan (Camptosar, CPT-11)	IV: 180 mg/m^2 over 90 min	Colon and rectal cancer. Can cause early (during administration or within 24 h) and late diarrhea. Pretreatment bowel function (without an antidiarrheal medication) should be maintained for at least 24 h before next dose of chemotherapy is given. Pregnancy category: D; PB > 90%; t½: 6 h
topotecan (Hycamtin)	IV: For ovarian cancer and SCLC: 1.5 mg/m^2/d infusion over 30 min for 5 d every 21 d For relapsed SCLC: PO: 2.3 mg/m^2/d for 5 d	Ovarian cancer, small-cell lung cancer. GI toxicities (nausea, vomiting, diarrhea common). Bone marrow suppression a dose-limiting toxicity. Pregnancy category: D; PB >35%; t½: 2-3 h
Retinoids		
bexarotene (Targretin)	PO: 300 mg/m^2/d for 97 wk	Cutaneous T-cell lymphoma. Associated with birth defects in humans. Do *not* administer to pregnant patients. Pregnancy category: X; PB >99%; t½: 7 h
thalidomide (Thalomid)	PO: 200 mg/d	Multiple myeloma and skin lesions related to erythema nodosum leprosum. Banned by FDA in the 1960s for causing birth defects. NEVER give to pregnant patients. Pregnancy category: X; PB 55%-65%; t½: 5-7 h

Note: Chemotherapeutic doses and schedules will vary depending on protocol, body surface area (m^2), age, functional status, and comorbid conditions. For a full discussion of body surface area in dosage calculation, see Chapter 14.

CBC, Complete blood cell count; *d,* day; *h,* hour; *PB,* protein-binding; *t½,* half-life; *UK,* unknown; *WBC,* white blood cell; *wk,* week.

Pharmacodynamics Vincristine is used in chemotherapy protocols to treat acute and chronic leukemia, Hodgkin's disease, non-Hodgkin's lymphoma, neuroblastoma, sarcoma, Wilms' tumor, breast cancer, and lung cancer. The onset of action begins in a few minutes; however, the therapeutic effect may take several days. *Vincristine is an anticancer drug that is only administered IV.*

Side Effects and Adverse Reactions

Several drug interactions may occur with vincristine (Oncovin). The patient should report all medications that he or she is taking, including OTC medicines and herbal supplements. Serious drug interactions can occur when taking vincristine (Oncovin) and L-asparaginase (Elspar), the cardiac medication digoxin (Lanoxin), phenobarbital (Solfoton), calcium channel blockers, and mitomycin (Mutamycin).

Nursing Process
Patient-Centered Collaborative Care

Plant Alkaloids: Vincristine

Assessment

- Conduct a detailed medication history, including a list of all concurrent medications, including prescriptions, over-the counter medicines, antacids, dietary supplements, vitamins, and herbal supplements to avoid drug-drug interactions.
- Obtain baseline information about patient's physical status. This should include height, weight, vital signs, laboratory values (CBC, uric acid, electrolytes, hepatic and renal studies, cardiopulmonary assessment, intake and output, skin assessment, daily activities status [i.e., ability to perform ADLs], sleep-rest cycle), nutritional status, presence or absence of underlying symptoms of disease, and the use of current or past medications and treatment.
- Assess laboratory results at the beginning of therapy and at specified time intervals (ranging from weekly to monthly) during therapy. Drug may be withheld if red blood cell, white blood cell, or platelet counts drop below predetermined levels.
- Assess CBC, differential, and platelet count weekly.
- Monitor bilirubin levels. Dose may be reduced if bilirubin levels are >1.5 mg/dL.
- Conduct a thorough physical assessment, and document findings. Be especially aware of evidence of neurotoxicity, because this is a dose-limiting toxicity.
- Assess for signs of peripheral neuropathy (numbness or tingling in fingers or toes), loss of deep tendon reflexes, foot drop, slapping gait, and difficulty walking.
- Monitor bowel function. Autonomic neuropathy may lead to constipation and paralytic ileus. The use of vincristine and narcotic analgesics may increase the risk of constipation.
- Assess temperature; fever may be an early sign of infection.
- Monitor for acute bronchospasm.
- Obtain baseline data regarding patient's psychosocial status, including educational level, ability and desire to learn, support systems, past coping strategies, presence or absence of emotional difficulties, and self-care abilities.
- Assess patient and family knowledge related to therapeutic regimen.
- Assess plans for pregnancy (if appropriate).

Nursing Diagnoses

- Risk for infection related to bone marrow suppression
- Risk for constipation related to neuropathic side effects of chemotherapy
- Ineffective breathing pattern related to bronchospasm secondary to rapid infusion
- Risk for injury related to neuropathic side effects of chemotherapy
- Deficient knowledge related to antineoplastic therapy

Planning

- Patient will maintain blood cell values in the desired range.
- Patient will maintain adequate bowel function.
- Patient will be free from neuropathic dysfunction.
- Patient will be free from respiratory complications (bronchospasm).
- Patient/family/caregiver will demonstrate understanding of the chemotherapy regimen, including side effects.

Nursing Interventions

- Assess for signs of respiratory distress during and after administration.
- Monitor for signs of peripheral neuropathy (numbness and/or tingling in hands and/or feet, sensory loss, loss of deep tendon reflexes, paresthesia, foot drop, wrist drop, ataxia).
- Assess IV site carefully. Vincristine is a severe vesicant whose effects are not immediately apparent. Give drug through a large-bore, quickly running IV infusion. Monitor blood counts and laboratory values.
- Extravasation produces severe pain. If extravasation occurs, stop infusion immediately. Do not remove IV device from the patient. Attempt to aspirate residual vesicant from the IV device using a small syringe, and then remove the IV device. Assess the site. Notify health care provider. Apply warm packs for 15 to 20 minutes at least 4 times per day for first 24 hours. For peripheral extravasations, elevate extremity. Tissue necrosis may occur 3 to 4 weeks after infiltration into tissue.
- Administer antiemetic 30 to 60 minutes before chemotherapy, or as prescribed.
- Assess bowel function.
- Administer stool softener or laxative as prescribed.
- Monitor fluid intake and output, and nutritional intake.
- Maintain strict medical asepsis during dressing changes and invasive procedures.

Patient Teaching

General

- Advise patient to promptly report signs of infection (e.g., fever, sore throat), bleeding (e.g., bleeding gums, petechiae, bruises, hematuria, blood in the stool), and anemia (e.g., increased fatigue, dyspnea, orthostatic hypotension).

- Teach patient the signs and symptoms of neurotoxicity (numbness and/or tingling in hands and/or feet, sensory loss, loss of deep tendon reflexes, paresthesia, foot drop, wrist drop, ataxia). Inability to button clothes or to close zippers may be an early sign of peripheral neuropathy.
- Emphasize protective precautions (e.g., hand washing, personal hygiene) as necessary.
- Advise patient not to visit anyone who has a respiratory infection. A decreased WBC count puts patient at risk for acquiring an infection.
- Teach patient signs of "stocking/glove" syndrome (numbness/tingling of hands and feet). This may last as long as 1 year or may never completely resolve.
- Teach patient that complete alopecia may occur. Teach patient that hair will begin to regrow within several months after therapy is completed.
- Teach importance of using birth-control measures as appropriate. Discuss sperm banking with male patients as appropriate.
- Teach patient that in most situations pregnancy should be avoided for 3 to 4 months after completing antineoplastic therapy. Some sources recommend that both men and women avoid conception for 2 years after completion of treatment.

Side Effects

- Teach patient the signs of peripheral neuropathy.
- Teach patient to report constipation and abdominal pain.
- Assess for nausea and vomiting; administer antiemetics as prescribed.
- Advise patient of possible hair loss; recommend a wig, hairpiece, scarf, or turban.
- Teach importance of using birth-control measures as appropriate. Discuss sperm banking with male patients as appropriate.
- Remind premenopausal women that they may experience amenorrhea, menstrual irregularities, or sterility; advise male patient that he may experience impotence.
- Assess for use of alternative/complementary therapy that may interact with chemotherapy agent.
- Teach patient the signs of tissue extravasation, which can occur 3 to 4 weeks after administration of the drug.

Diet

- Encourage bulky high-fiber foods, adequate fluid intake, and moderate exercise to reduce risk of constipation.

Cultural Considerations

- In some cultural groups, health care decisions are made by consensus, and the family plays a key role in filtering information given to the patient. Issues related to informed consent and full disclosure of medical information may cause distress in cultural groups that place the needs of the family above the needs of the individual. Interactions should be modified based on family structure, religious values and beliefs, time orientation, cultural health practices, and verbal and nonverbal communication.
- Cultural assessment tools can provide general guidelines for health care providers.
- Asians may be at increased risk for hyponatremia and SIADH.

Evaluation

- Patient is free from infection.
- Bowel function is maintained.
- Peripheral neuropathy did not occur.
- Side effects of therapy are controlled.
- Extravasation and tissue necrosis did not occur.
- Patient/family/caregiver educational needs are met.

TARGETED THERAPIES

Chapter 38 provides in-depth information on this treatment modality.

LIPOSOMAL CHEMOTHERAPY

A more recent change in the delivery of chemotherapy involves the use of anticancer drugs that have been packaged inside synthetic fat globules called *liposomes*. The fatty coating helps the chemotherapy drug remain in the system longer, decreases side effects (e.g., hair loss, nausea, cardiotoxicity), and increases the duration of therapeutic effects. Encapsulated forms of doxorubicin (Doxil, Caelyx, Myocet), daunorubicin (DaunoXome), and Cytarabine (DepoCyt) are examples of liposomal chemotherapy.

HORMONAL AGENTS

Although **hormones** are not considered true chemotherapeutic agents, several classes of hormonal agents are used in the treatment of cancer. These include corticosteroids, sex hormones, antiestrogens, aromatase inhibitors, gonadotropin-releasing hormone analogues, and antiandrogens.

Corticosteroids

Corticosteroids (glucocorticoids) are antiinflammatory agents that suppress the inflammatory process that is associated with tumor growth. Although the exact mechanism of action is unknown, these agents may block steroid-specific receptors on the surface of cells. This blocking action slows the growth fraction of the tumor, thus retarding its growth. Prednisone (Cordrol, Deltasone), dexamethasone (Cortastat, Dalalone), and hydrocortisone (Hydrocortone, Solu-Cortef) can help decrease cerebral edema caused by a malignant brain tumor. Cortisone drugs give the patient a sense of well-being and varying degrees of euphoria. Cortisone derivatives taken internally produce many adverse side effects, including fluid retention, potassium loss, increased risk for infection, increase in blood sugar, increased fat distribution, muscle weakness, increased bleeding tendency, and euphoria.

Sex Hormones

The sex hormones (e.g., estrogen, androgen) or hormone-like agents are used to slow the growth of hormone-dependent tumors (e.g., prostate cancer, breast cancer). Estrogen therapy is a palliative treatment used to decrease the progression of prostatic cancer in men and to slow the growth of hormone-dependent breast cancer in women. Estrogen preparations suppress tumor growth and may induce remission of the cancer for up to 1 year. Examples of this group of drugs are diethylstilbestrol (Stilbestrol), ethinyl estradiol (Estinyl), chlorotrianisene (TACE), and conjugated estrogens (Premarin).

Progestins may be prescribed to treat breast cancer, endometrial carcinoma, and renal cancer. These drugs (e.g., hydroxyprogesterone caproate [Duralutin]), medroxyprogesterone acetate [Depo-Provera], and megestrol acetate [Megace]) act by shrinking the cancer tissues. Adverse reactions include fluid retention and thrombotic (clot) disorders.

Androgens are given to treat advanced breast cancer in premenopausal women. This male hormone promotes regression of tumors. If androgen therapy is used over a long period of time, masculine secondary sexual characteristics, such as body hair growth, lowering of the voice, and muscle growth, will occur. Antiestrogens such as tamoxifen (Nolvadex) and fulvestrant (Faslodex) are used to treat breast cancer tumors that are estrogen-receptor positive (ER+). Tamoxifen has shown proven efficacy in preventing tumor recurrence in both premenopausal and postmenopausal women, but it has a number of side effects associated with it. These include hot flashes, irregular menses, fatigue, headaches, nausea, and vomiting. Men who take tamoxifen may experience headaches, impotence, and a decreased interest in sexual activity. Tamoxifen increases a woman's risk for developing cancer of the uterus.

Selective estrogen receptor modulators (SERMs) act like antiestrogens to slow tumor growth, but have fewer side effects than tamoxifen. SERM drugs currently in use include raloxifene (Evista) and toremifene (Fareston). A new generation of SERM drugs is currently being evaluated to determine effects on preventing recurrent breast cancer, decreasing postmenopausal bone loss, and reducing the risk of cardiovascular disease.

Prototype Drug Chart 37-4 details the pharmacologic behavior of vincristine (Oncovin).

SAFETY: Preventing Medication Errors

Do not confuse …

- **vincristine** with **vinblastine**

Gonadotropin-Releasing Hormone Analogues

Luteinizing hormone-releasing hormone (LH-RH) agonists (e.g., leuprolide [Lupron], goserelin [Zoladex]) suppress the secretion of follicle-stimulating hormone and luteinizing hormone from the pituitary gland. Initially an increase in testosterone levels is seen. However, with continued use the pituitary gland becomes insensitive to this stimulation, leading to a reduction in the production of androgens and estrogens.

Antiandrogens

Antiandrogens (e.g., flutamide [Eulexin], nilutamide [Nilandron], bicalutamide [Casodex]) are useful in treating men with hormone-responsive prostate cancer that has metastasized. These agents work by binding to androgen receptors and blocking the effects of dihydrotestosterone on the prostate cancer cells.

Aromatase Inhibitors

In postmenopausal women, the ovaries no longer produce estrogen, but androgen is converted to estrogen in this group of women. The aromatase inhibitors block the peripheral conversion of androgens to estrogens, thus suppressing the postmenopausal synthesis of estrogen and slowing tumor growth. Aromatase inhibitors are used in the treatment of hormonally sensitive breast cancer in postmenopausal women or premenopausal women who have had their ovaries removed. Anastrozole (Arimidex), letrozole (Femara), and exemestane (Aromasin) are examples of aromatase inhibitors currently in use. Increasingly these agents are being used before tamoxifen in postmenopausal women with hormonally responsive metastatic breast cancer. Table 37-7 lists hormonal agents, uses, and considerations.

MISCELLANEOUS CHEMOTHERAPY AGENTS

This category includes a number of antineoplastic agents in which the mechanism of action is unclear. Table 37-7 describes two: asparaginase (Elspar) and pegaspargase (Oncaspar).

Vaccines

Vaccines used to prevent cancer include the hepatitis B vaccine, given to prevent infection with the hepatitis B virus, which can cause liver cancer. Two recombinant vaccines, Gardasil and Cervarix, are given to girls and young women 9 to 26 years of age to prevent HPV infections that can cause cervical cancer. Cervarix is used for boys and young men 9 to 26 years of age to prevent HPV types 6 and 11, which can cause genital warts. Several experimental vaccines have shown promise in the treatment of prostate cancer.

SAFETY: Preventing Medication Errors

Do not confuse …

- **busulfan** with **Buscopan**
- **Taxotere** with **Taxol**
- **floxuridine** with **Floxin**
- **hydroxyurea** with **hydroxyzine hydrochloride**
- **Oxaliplatin** with **oxaprozin**
- **topotecan** with **Toposar**

PROTOTYPE DRUG CHART 37-4

Vincristine

Drug Class

Plant alkaloid/vinca alkaloid
Trade Name: Oncovin
Pregnancy Category: D

Dosage

A: IV: use only via free-flowing IV catheter. 0.4-1.4 mg/m^2 weekly. A 50% reduction in the dose recommended for those with a direct serum bilirubin value above 3 mg/100 mL
C: IV: use only via free-flowing IV catheter. 2 mg/m^2
For children <10 kg, starting dose is 0.05 mg/kg weekly
If peripheral neuropathies occur, reduction or discontinuance of therapy may be needed.

Contraindications

FATAL if given intrathecally
Do not give to patients receiving radiation therapy through ports into the liver.
Hypersensitivity
Do not give to patients with Charcot-Marie-Tooth syndrome.
Caution: Pregnancy, liver or kidney disease, neuromuscular disease, or infection

Drug-Lab-Food Interactions

Drug: Acute life-threatening bronchospasm may occur, especially if drug is given with mitomycin (Mutamycin).
L-asparaginase (Elspar) may reduce hepatic clearance of vincristine.
Vincristine decreases digoxin effects. Monitor digoxin levels.
Vincristine decreases phenytoin effects. Monitor patient for seizure activity.
Do not dilute in solutions that increase or decrease pH outside a range of 3.5-5.5.
Mix only with normal saline or glucose in water.
Herb: Use cautiously with bromelain (pineapple extract). *Catharanthus roseus* (periwinkle) may increase risk of bone marrow suppression when given with vincristine.
Lab: May cause hyponatremia, hyperuricemia, anemia, leukopenia, thrombocytopenia.

Pharmacokinetics

Absorption: IV
Distribution: PB: 75%
Metabolism: Liver t½: first phase, 5 min; second phase, 2¼ h; terminal phase, 85 h
Excretion: 80% in feces; 10%-20% in urine
Nadir: 7-10 d

Pharmacodynamics

Effects on blood count: Decreased
IV: Onset: 7 d
Peak: 10-14 d
Duration: 21 d

Therapeutic Effects/Uses

Acute leukemia, Hodgkin's disease, non-Hodgkin's lymphoma, neuroblastoma, rhabdomyosarcoma, Ewing's sarcoma, Wilms' tumor, multiple myeloma, acute and chronic leukemia, breast and lung cancers
Mode of Action: Affects cells in the M phase of the cell cycle, and inhibits mitosis

Side Effects

Peripheral neuropathy, loss of deep tendon reflexes, phlebitis, constipation, cramps, nausea, vomiting, muscle weakness, reversible alopecia

Adverse Reactions

Sensory loss, hypotension, visual disturbances, ptosis, ileus, SIADH, hyponatremia, hyperuricemia, severe local reaction with extravasation, fever
Life-threatening: intestinal necrosis, seizures, coma, acute bronchospasm, bone marrow suppression

d, Day; *h,* hour; *IV,* intravenous; *PB,* protein-binding; *SIADH,* syndrome of inappropriate antidiuretic hormone secretion; *t ½,* half-life; ≤, less than or equal to.

TABLE 37-7 ANTINEOPLASTICS: HORMONES, HORMONE ANTAGONISTS, AND MISCELLANEOUS

DRUG TYPE AND NAME	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Androgens		
testolactone (Teslac)	PO: 250 mg 4 times/d	Palliative treatment of breast carcinoma in postmenopausal women. Monitor serum calcium levels. Voice may deepen, and facial hair may increase. Pregnancy category: D; PB: UK; t½: UK
Hormonal Antagonists		
aminoglutethimide (Cytadren)	PO: 750-2000 mg/d in divided doses	Adrenal carcinoma, ectopic adrenocorticotropic hormone (ACTH)-producing tumors. Suppresses adrenal activity. May be used in breast cancer therapy. Treatment typically lasts for 3 mo. Pregnancy category: D; PB: 20%-25%; t½: 7-15 h
anastrozole (Arimidex)	PO:	Advanced breast cancer in postmenopausal women. Diarrhea, headache, hot flashes, pain, hypertension, and dyspnea might occur. Pregnancy category: D; PB: 40%; t½: 50 h
bicalutamide (Casodex)	anastrozole 1 mg/d bicalutamide 50 mg/d	
exemestane (Aromasin)	PO: 25 mg/d	Advanced metastatic prostatic carcinoma. Pregnancy category: X; PB: UK; t½: 5.8 d
flutamide (Eulexin)	PO: 250 mg every 8 h	Advanced breast cancer in postmenopausal women. Prostatic cancer. Pregnancy category: D; PB: UK; t½: 24 h

TABLE 37-7 ANTINEOPLASTICS: HORMONES, HORMONE ANTAGONISTS, AND MISCELLANEOUS—cont'd

DRUG TYPE AND NAME	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
fulvestrant (Faslodex)	IM: 500 mg as 2 5-mL injections, one in each buttock on days 1, 15, and 29 and once monthly thereafter	Metastatic prostatic carcinoma, usually in combination with other anticancer drugs. Pregnancy category: D; PB: 95%; t½: 5-10 h
goserelin acetate (Zoladex)	subQ: 3.6 mg/mo in upper abdominal wall every 28 d	Treatment of hormone-receptor positive metastatic breast cancer in postmenopausal women whose disease has progressed after antiestrogen therapy. Pregnancy category: D; PB: 99%; t½: 40 d
histrelin acetate implant (Vantas)	SubQ implant: 50 mg implanted under skin on upper, inner arm, every 12 months (remove old implant before placing new one)	Treatment of advanced prostate cancer. A small, thin implant is placed under the skin of the arm. Drug works for 12 mo, and then implant needs to be replaced. Pregnancy category: X; PB: 70%; t½: 3 h
letrozole (Femara)	PO: 2.5 mg/d	Metastatic prostatic carcinoma. Drug is a synthetic luteinizing hormone-releasing analogue. May also be used in breast cancer and endometriosis. Gynecomastia, breast swelling, and hot flashes may occur. Pregnancy category: X; PB: UK; t½: 4-6 h
leuprolide (Lupron, Viadur)	IM: Depot suspension 7.5 mg every mo Viadur implant 65 mg every 12 mo	Advanced breast cancer in postmenopausal women. Decreases estrogen biosynthesis. May be more effective than megestrol acetate and aminoglutethimide. Pregnancy category: UK; PB: UK; t½: 2 d
	subQ: 1 mg/d	Used to slow the growth of prostate cancer. Can be given daily (Lupron) or at 3- or 4-mo intervals (Lupron Depot). May be used to treat endometriosis. Hypersensitivity reactions may occur in people with allergy to benzyl alcohol. Pregnant patients should not take this drug (high risk of fetal damage). Pregnancy category: X; PB: 49%; t½: 3 h
megestrol acetate (Megace)	PO: 800 mg/d	Palliative treatment of advanced carcinoma of breast and endometrium. May Promote weight gain by increasing appetite. Pregnancy category: X; PB: UK; t½: 15-20 h
mitotane (Lysodren)	PO: 2-16 g/d	Palliative treatment of inoperable adrenal cortical carcinoma. Adverse reactions include hemorrhagic cystitis, hypouricemia, and hypercholesterolemia. Monitor vital signs. Pregnancy category: C; PB: UK; t½: 20-160 d
nilutamide (Nilandron)	PO: 300 mg/d for 30 d, then maintenance dose	Prostatic carcinoma. Loss of libido and sexual potency may occur. Monitor liver function. Pregnancy category: C: PB: UK; t½: 24-72 h
tamoxifen citrate (Nolvadex)	PO: 20 mg/d	Palliative treatment of advanced breast carcinoma with positive lymph nodes in postmenopausal women. Competes with estradiol at estrogen receptor sites. Decreases DNA synthesis. Reduces risk of breast cancer in postmenopausal women. Pregnancy category: D; PB: UK; t½: 7 d
raloxifene (Evista)	PO: 60 mg daily	Selective estrogen receptor modulator (SERM) originally approved to fight osteoporosis in postmenopausal women. Reduces risk of breast cancer with fewer side effects than tamoxifen. Pregnancy category: X; PB: 95%; t½: 27 h
toremifene citrate (Fareston)	PO: 60 mg/d	Advanced breast cancer in postmenopausal women. An antiestrogen drug. Pregnancy category: D; PB: >99%; t½: 5 d
Miscellaneous Enzymes		
asparaginase (Elspar, L-asparaginase)	IV: For leukemia induction: 200 units/kg/d for 28 d	Acute lymphocytic leukemia. Used in combination with another anticancer drug. Common side effects include nausea, vomiting, anorexia, leukopenia, and impaired pancreatic function. Pregnancy category: C; PB: 30%; t½: 8-30 h (IV)
pegaspargase (Oncaspar)	Teenagers up to 21 years of age: 2500 units/m^2 every 14 d C: BSA 0.6 m 2500 units/m every 14 d	Acute lymphoblastic leukemia. CCS agent that affects G1 phase of cell cycle. Interferes with DNA, RNA, and protein synthesis. Pregnancy category: C; PB: UK; t½: 1.4-5.2 d
Vaccines		
Hepatitis B (Engerix-B, Recombivax HB)	IM: given in a series of 3 doses: 0, 1, and 3 mo	First anticancer vaccine. Prevents hepatitis B and its serious consequences such as hepatocellular carcinoma (liver cancer).
Gardasil (quadrivalent human papillomavirus [types 6, 11, 16, 18] recombinant vaccine)	IM: 0.5 mL given in a series of 3 shots (0, 2, and 6 mo) in deltoid region of upper arm	For vaccination of women 9 to 26 years of age for prevention of diseases caused by human papillomavirus (HPV) types 6, 11 (genital warts), 16, and 18 (cervical cancer).
Cervarix	IM: 0.5 mL given in a series of 3 shots (0, 1, and 6 mo) in deltoid region of upper arm	For prevention of cervical cancer and precancerous lesions associated with most common cancer-causing HPV types.

Note: Chemotherapeutic doses and schedules will vary depending on protocol, body surface area (m^2), age, functional status, and comorbid conditions. For a full discussion of body surface area in dosage calculation, see Chapter 14.

CCS, Cell cycle–specific; *d,* day; *DNA,* deoxyribonucleic acid; *h,* hour; *IV,* intravenous; *min,* minute; *mo,* month; *PB,* protein-binding; *RNA,* ribonucleic acid; *t½,* half-life; *UK,* unknown; *wk,* week; *>,* greater than.

Oncology Nursing Society: *www.ons.org/ClinicalResources*

CRITICAL THINKING CASE STUDY

A 63-year-old patient, recently diagnosed with breast cancer, is scheduled to receive combination chemotherapy consisting of IV fluorouracil (5-FU, Adrucil), doxorubicin (Adriamycin), and cyclophosphamide (Cytoxan). This therapy is designated by the acronym *FAC (fluorouracil, Adriamycin, cyclophosphamide)*. The patient's treatment regimen consists of the following: fluorouracil, 500 mg/m^2 IV, Day 1; doxorubicin 50 mg/m^2 IV, Day 1; cyclophosphamide, 500 mg/m^2 IV, Day 1. This cycle is to be repeated every 21 days for 6 cycles.

1. Differentiate the drug actions of fluorouracil, doxorubicin, and cyclophosphamide.
2. What side effects and adverse reactions should the nurse assess for during therapy? Why would assessment of the cardiac, GI, and genitourinary systems be important with this drug regimen?
3. What is the maximum lifetime dose for doxorubicin? Why is this so important?
4. Describe the early signs of cardiotoxicity that might be seen days to months after the administration of doxorubicin.
5. Briefly explain why hydration would be important during this drug regimen.
6. What nursing interventions would be appropriate when caring for this patient?
7. Describe the teaching that the nurse would provide to the patient and her family.
8. After two cycles of chemotherapy, the patient complains that her mouth feels sore and that it hurts to eat. Which chemotherapy agent is most likely responsible for this finding? What nursing interventions would be initiated to address this problem?
9. Analyze protective measures necessary to avoid accidental exposure to chemotherapy agents during administration.
10. The patient calls the outpatient oncology clinic and tells the nurse that she has a temperature of 101° F (38.3° C). What actions should the nurse take to address this issue?

NCLEX STUDY QUESTIONS

1. A patient is to receive a chemotherapy protocol that includes an alkylating agent, an antimetabolite, and an antitumor antibiotic. The patient asks the nurse why so much chemotherapy is needed. What is the nurse's best response?
   a. A protocol that uses a combination of chemotherapeutic agents works in the S-phase to kill cells.
   b. The rationale for using combination chemotherapy is that it increases the extent of tumor cell kill.
   c. Combination chemotherapy uses drugs that work the same way.
   d. An outcome of the use of combination chemotherapy is that it has no dose-limiting toxicities.

2. A patient is scheduled to receive chemotherapy drugs that will cause myelosuppression. Which action by the nurse will be most important?
   a. Monitor for a change in temperature.
   b. Evaluate gastrointestinal function.
   c. Assess for evidence of cardiac compromise.
   d. Question the patient about changes in sense of taste.

3. The nurse is caring for a patient with colorectal cancer who is to receive fluorouracil. Which symptom will be most important for the nurse to report to the health care provider?
   a. Nausea
   b. Decreased appetite
   c. Stomatitis
   d. Constipation

4. A patient in the outpatient oncology clinic complains of fatigue after receiving chemotherapy. Which nursing intervention will be most appropriate?
   a. Assess for other factors contributing to her fatigue (e.g., trouble sleeping).
   b. Encourage a high-protein, high-calorie diet designed with the patient.
   c. Refer the patient to a physical therapist to develop a strenuous exercise program.
   d. Encourage the patient to sleep as much as possible during the day to ease fatigue.

5. A patient in the outpatient oncology clinic has developed mucositis after receiving fluorouracil. Which statement made by the patient indicates the need for additional teaching about mucositis?
   a. "I will frequently rinse out my mouth with normal saline."
   b. "To relieve my mouth pain, I will use ice pops or ice chips."
   c. "In order to clean my mouth, I will use mouthwash with alcohol."
   d. "Using a soft toothbrush will clean my teeth and freshen my breath."

6. A patient is scheduled to receive high-dose cyclophosphamide via IV infusion as treatment for cancer. Which will be most important for the nurse to include when teaching the patient about cyclophosphamide?
   a. An indwelling urinary catheter will be placed.
   b. Drink at least 2 L of fluid per day.
   c. Empty the bladder every 4 to 6 hours.
   d. Limit fluid intake during chemotherapy.

7. A nurse is administering doxorubicin to a patient in the outpatient oncology clinic. Which information would be most important for the nurse to include in patient teaching?
   - **a.** Blood counts will most likely remain normal.
   - **b.** Complete alopecia rarely occurs with this drug.
   - **c.** Report any shortness of breath, palpitations, or edema to the health care provider.
   - **d.** Tissue necrosis usually occurs 2 to 3 days after administration.
8. A patient diagnosed with cancer is scheduled to receive vincristine. Which nursing assessment will have the highest priority when providing care for this patient?
   - **a.** Degree of alopecia
   - **b.** Increased digoxin (Lanoxin) levels
   - **c.** Decreased phenytoin (Dilantin) effects
   - **d.** Peripheral neuropathy
9. A patient is experiencing mucositis (stomatitis) secondary to receiving chemotherapy. Which symptomatic treatments will be appropriate? (Select all that apply.)
   - **a.** Frequent mouth rinses
   - **b.** Antiemetics
   - **c.** Topical anesthetics
   - **d.** Stress reduction
   - **e.** Antibiotics
10. A nurse is teaching a patient who will receive chemotherapy that will cause thrombocytopenia. Which instructions will the nurse include in the patient's teaching plan? (Select all that apply.)
    - **a.** Use an electric razor when shaving.
    - **b.** Use a soft-bristled toothbrush.
    - **c.** Use aspirin for pain or headache.
    - **d.** Monitor oral temperature daily.
    - **e.** Report any bleeding (gums, petechiae, bruises, hematuria, melana) to the health care provider.
11. The nurse is caring for a patient who has completed a chemotherapy protocol 10 days ago, and the drug's nadir occurs on days 7 to 14. Current laboratory values are hemoglobin 12.8 mg/dL, platelet count 162,000/mm^2, and white blood cell count 2.100/mm^2. Which action will be most appropriate for the nurse to implement?
    - **a.** Wear a gown and mask each time you enter the patient's room.
    - **b.** Advise the patient to avoid every person who has been vaccinated.
    - **c.** Emphasize protective precautions (hand washing, personal hygiene).
    - **d.** Encourage frequent periods of rest.

OBJECTIVES

- Compare the mechanisms of action of targeted therapies for cancer with those of standard chemotherapy drugs.
- Distinguish among the different types of targeted therapies for cancer treatment with regard to indications, possible side effects and adverse effects, route of administration, and nursing responsibilities.
- Incorporate the nursing process related to the needs of patients receiving targeted therapies for cancer.
- Develop and evaluate a focused teaching plan for patients/family/caregivers about the use and side effects of targeted therapy for cancer.

As described in Chapter 37 and in the Unit XII opener, cancers develop from normal cells that have sustained gene damage. Cancer cells differ from normal cells in many ways, especially in their unrelenting growth and invasive spread (metastasis). This excessive growth serves no useful function and causes death when cancer cells invade normal tissues to the extent that vital organs can no longer perform their life-sustaining functions.

Traditional chemotherapy is generalized, systemic, chemical, **cytotoxic** treatment that directly kills or severely damages cells. Mechanisms of action for different categories of

---

chemotherapy drugs vary, but the overall outcome is the inhibition of cell division (**mitosis**) and cell death. Often, these drugs damage the cell DNA to prevent DNA replication and formation of new cancer cells (see Chapter 37). This form of treatment has improved cancer control and increased long-term survival. Although these drugs have some selectivity for exerting cytotoxic effects on cancer cells, the drugs also have a toxic impact on many normal cells. As a result, acute side effects of traditional combination chemotherapy are uncomfortable and can be life-threatening. Thus, the cancer cell–killing effect of traditional chemotherapy is limited by the dosages and scheduling regimens needed to reduce toxic side effects on normal cells.

Targeted therapy for cancer treatment differs from traditional cancer chemotherapy by taking advantage of biologic features, such as cellular receptors, enzymes, pathways, or other molecular proteins of cancer cells that either are not present or are present in much smaller quantities in normal cells. Thus, targeted therapies are more *specific* in their mechanisms and effects than traditional cancer chemotherapy agents. The National Cancer Institute's (NCI) defines targeted therapy as drugs or other substances that block the growth and spread of cancer by interfering with specific molecules involved in tumor growth and progression. It is important to remember that, unlike traditional cytotoxic chemotherapy (which exerts its effects by damaging the DNA of nearly *any* cell), targeted therapies require a specific molecular target as the recipient of their effects. The increased specificity of targeted therapies also means that more tests are required on cancer cells to determine whether a target is present in sufficient amounts to make the targeted therapy effective. For example, not all breast cancer cells have the molecular target for trastuzumab (Herceptin), and not all leukemia cells have the molecular target for imatinib (Gleevec). *Cancers that do not have sufficient quantities of the specific molecular target will not respond to targeted therapy.*

PATHOPHYSIOLOGY

Normal Cell Growth Regulation

Genetic Control over Cell Division

As shown in Figure XII-1 at the beginning of Unit XII, which depicts the cell cycle, cell cycle checkpoints must be overcome to enter the cell cycle and continue to progress through each phase of the cycle to mitosis. Initially, general factors determine whether the cell enters the cell cycle.

Signal transduction is a method of communication that allows events, conditions, and substances outside of the cell to influence the cell's decision to divide, not to divide, or to perform its designated function. Some of the known external and internal signaling substances that promote cell division are enzymes; growth factors; adhesion proteins; steroid hormones; and cell-to-cell physical, chemical, and electrical interactions. Figure 38-1 shows a segment of a cell with one interconnecting signal transduction pathway that, when activated, leads to gene activation for those proteins that promote cell division. This pathway can be activated by growth factors binding to their receptors, the interaction of certain drugs with the cell plasma membrane, the presence of adhesion proteins, changes in ion movement (especially sodium and calcium), ligand binding, and other cell-to-cell interactions. When any of these conditions activate the signal transduction pathway, the amount of tyrosine kinases inside the cell is increased.

Tyrosine kinases (TKs) are a family of enzymes that activate other substances by adding a phosphate group (PO_4) to them, a process known as *phosphorylation*. There are many different TKs. Some are unique to the cell type; others may be present only in cancer cells that express a specific gene mutation. Regardless of how a pro–cell-division signal transduction pathway is activated, the result is an increase in TK levels that propagate the signal by activating a variety of transcription factors within the pathway.

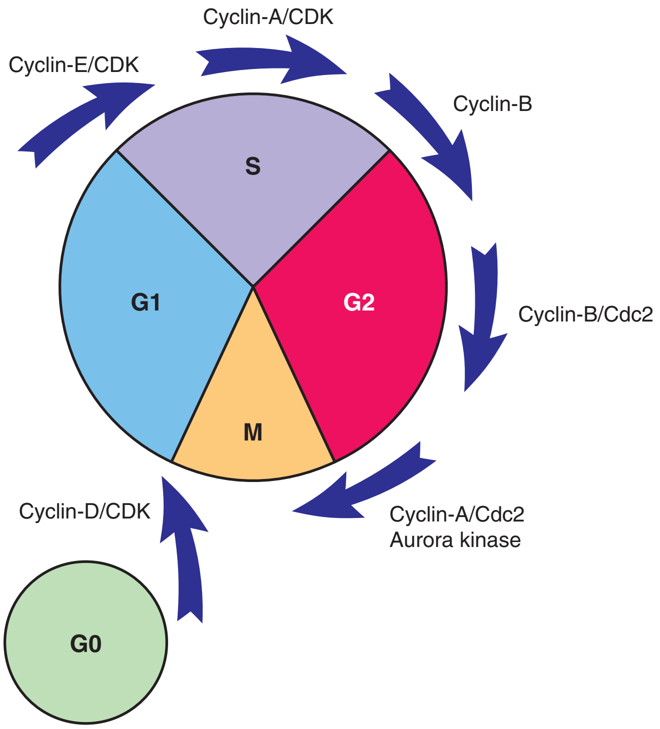

FIGURE 38–2 Cyclin activity promoting progression through the cell cycle.

Transcription factors for cell division are substances that enter the nucleus and signal the cell that mitosis is needed. Many different types of substances serve as transcription factors. The overall response is greater expression of oncogene products (cyclins) that promote cell division, and the reduced expression of **suppressor gene** products that inhibit cell division. When the cell responds to these mitotic signals indicating that cell division is needed and resources are adequate, the cell leaves the G_0 phase and enters the G_1 phase of the cell cycle. Once the cell enters the G_1 phase, the presence of specific cyclins determines whether it can progress to the next phase (Figure 38-2).

SAFETY: Preventing Medication Errors

Do not confuse…

- **trastuzumab** (Herceptin) with **tositumomab** (Bexxar)
- **bortezomib** (Velcade) with **bevacizumab** (Avastin)

Cyclins are part of a family of proteins that, when active, stimulate the cell to move through the cell cycle. They are the products of oncogenes, and most are activated when a phosphorous group is added to the cyclin chemical structure. (Removal of a phosphorous molecule from a cyclin [*dephosphorylation*] inhibits its activity.) Kinases that activate cyclins are *cyclin-dependent kinases* (CDKs). CDKs combine with cyclins to form complexes that initiate cell mechanisms to complete cell division. In normal cells, the oncogenes that produce cyclins are carefully regulated by suppressor gene products so that cell division only occurs when it is needed and to the degree that it is needed.

The amount and type of cyclins as well as which specific CDK is present in the cell during cell division vary by the phase of the cycle. These differences in types of cyclins and CDKs determine when or if a particular cell moves from one phase of the cycle to the next. Many different groups of cyclins have been identified, with the D group being most well understood.

A common signal for entering and starting the cell cycle at G_1 is the combining of a cyclin-D with the appropriate CDK to form a cyclin-D/CDK complex (see Figure 38-2). Movement of the cell from G_1 into the S, G_2, and M phases of the cell cycle is regulated by the continued presence of pro–cell-division transcription factors that promote DNA transcription and increased synthesis of specific pro–cell-division cyclins and CDKs.

Even when cell division is needed, the process is well controlled in normal cells. Proteins synthesized by suppressor genes determine how much oncogene expression is needed to allow cell division to occur but not lead to excessive cell division. Such control is exemplified by normal wound repair. For example, when a person falls and scrapes skin from the knee, the skin cells at the edge of the wound are signaled to divide and fill in the gap. When the wound area is closed, cell division normally stops. The person does not have uncontrolled cell division in this area to the extent that a large skin flap develops over and past the wound site.

When cell division is not needed, external signals, such as growth factor inhibitors and the surrounding of a cell plasma membrane with other cells, send signals that are inhibitory to the pro–cell-division signal transduction pathway (Figure 38-3). The result of this inhibition leads to low levels of TKs and reduced levels of pro–cell-division transcription factors. Instead, suppressor gene activity is increased, resulting in production of more suppressor gene products that inhibit the synthesis of cyclins and CDKs by oncogenes. There are many suppressor genes, and, although all are present in every cell type, specific suppressor genes may be more active in selected types of tissues. For example, the *BRCA1* suppressor gene appears most active in suppressing excessive cell division in breast, ovary, and genitourinary tract tissues. One of the most well-characterized suppressor genes is the *Tp53* suppressor gene. Its gene product restricts the entry of cells into the cell cycle and restricts progression through the cell cycle for many cell types. Without suppressor gene products, oncogenes would be overexpressed continually, leading to uncontrolled and unneeded cell division.

Internal cell conditions, such as poor cell nutrition and reduced energy stores, can trigger the activation of suppressor genes to disrupt the pro–cell-division signal transduction pathway, even when external conditions indicate a need for cell division (Figure 38-4). Thus, healthy and active suppressor genes guard against cell division when it is not in the body's best interest.

Genetic Control over Cell Death

As some cells age, they begin to function less optimally. When a cell is damaged, reduced function occurs at an earlier cell age. In normal tissues that are capable of cell division, damaged cells and older cells respond to signals for **apoptosis**, which is programmed cell death, intended to ensure that tissues and organs contain only healthy and optimally functional cells. Apoptosis is under strict genetic control in normal tissues so that healthy functional cells do not self-destruct faster than they can be replaced, and that older or damaged cells unable to perform vital functions do not overpopulate a tissue and reduce organ efficiency. Maintenance of optimally functional organs depends on a balance of cell division with apoptosis.

The signals for apoptosis may come from the aging cell with the loss of telomeric DNA. **Telomeric DNA** is special DNA that caps the ends of each chromosome much like plastic tips cap the ends of a shoelace to prevent raveling (Figure 38-5). The function of telomeric DNA is to maintain the integrity of the double DNA strands within each chromosome. With each round of cell division, the telomeric DNA shortens. When the cell has undergone its lifespan's worth of cell divisions, the telomeric DNA that capped the chromosomes is gone, allowing the DNA to unravel and fragment.

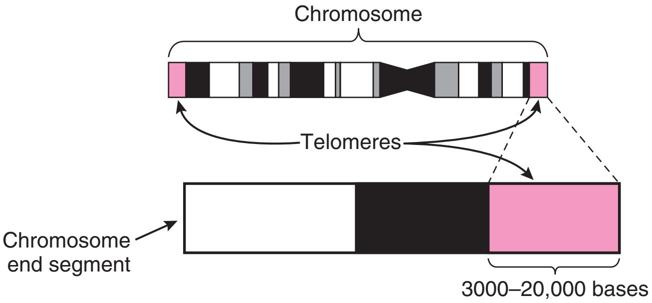

FIGURE 38–5 Chromosome with telomeric DNA and chromosome end segment with telomeric DNA.

These processes then trigger genetic and other intracellular signals for self-destruction through the action of autoenzymes, especially caspase 9. Activated caspase 9 leads to a cascade reaction for rapid activation of many more types of caspase enzymes. These enzymes degrade the cell's internal structures and cause the plasma membrane to lyse and break the cell into small fragments that are removed from the body by white blood cells.

Apoptosis is regulated by different gene products, including those of the *Tp53* (tumor protein 53) suppressor gene. When cells reach a certain age or experience DNA damage, the *Tp53* gene is expressed and older or damaged cells either undergo apoptosis or are prohibited from progression through the cell cycle.

Growth Regulation and Cancer

Loss of Genetic Control of Cell Growth. As stated earlier in the chapter, cancers develop from cells that were once normal. Normal cells become cancer cells when external or internal conditions lead to gene damage. Although cancer can develop from a normal cell that has sustained damage to its oncogenes, most commonly, one or more suppressor genes are damaged and are no longer able to control oncogene expression. As a result of excessive oncogene expression, cyclins and CDKs are overproduced and cell division occurs when it is not needed.

Excessive cell division from gene damage/mutations appears to be self-perpetuating, leading to further gene mutations that do the following:

- Allow one or more specific pro–cell-division signal transduction pathways to become more active
- Allow greater expression of cancer cell membrane receptors that trigger pro–cell-division signal transduction pathways
- Increase or amplify the production of specific TKs and transcription factors

Loss of Apoptosis. Mutations that occur in suppressor genes as a result of DNA damage inactivate the suppressor genes, preventing them from controlling oncogene activity. Some suppressor genes, such as the *Tp53* gene, also regulate apoptosis. Inactivation of suppressor genes that regulate apoptosis makes cancer cells unresponsive to apoptotic signals. These cancer cells are now resistant to natural cell death, a feature known as *cellular immortality*. The combined effects of lack of regulation for cell division and the loss of apoptosis result in cancer cells having no balance between cell division and apoptosis. This unbalanced condition favors continuous cancer cell division.

TARGETED THERAPY DRUGS

Targeted cancer therapies are a relatively new approach in cancer treatment. They work by interfering with cancer cell growth and division in different ways. These drugs are broadly known as *signal transduction inhibitors*. Targeted therapies generally inhibit cancer cell division by blocking a cancer membrane receptor, blocking tyrosine kinase activity, interfering with signal transduction, stimulating an immune system attack on cancer cells, or inducing the cell to undergo apoptosis. These agents may be used as monotherapy (a single agent), in combination with traditional chemotherapy, and with radiotherapy. Some targeted therapies are oral and are self-administered at home where it is convenient for patients; others are administered parenterally. All targeted therapies to treat cancer are categorized as high-alert medications.

The rapid identification of specific cancer-cell targets in recent years has led to an increased development of targeted therapies. Some are in relatively common use, and others are used less frequently or for rarer cancer types. Management of patient issues related to targeted therapies is an evolving area of study. With many targeted therapies being new to the market, costs can be high and may not be covered by insurance. New targeted therapies are approved frequently. Older targeted therapy drugs may be newly approved for use in a different way or with a different cancer type. Expect to see indications for use of different targeted therapies in additional cancer types in the future. Because newly approved therapies have been less widely used and their adverse effects are not yet fully characterized, this chapter focuses on therapies that have been in use for 1 year or more.

There are several major classes of targeted cancer therapies, based on their most common mechanism of action (Table 38-1). Some targeted therapies have more than one action. Those discussed in this chapter include tyrosine kinases inhibitors, multikinase inhibitors, epidermal growth factor/receptor inhibitors, vascular endothelial growth factor/receptor inhibitors, proteasome inhibitors, angiogenesis inhibitors, and monoclonal antibodies. The targeted therapies have been divided into two categories: monoclonal antibody (MoAb) and small-molecule inhibitor.

Tyrosine Kinase Inhibitors

Several types of targeted therapies have as an outcome the inhibition of tyrosine kinases using a variety of mechanisms. Specific drugs that cause this action as their main mechanisms are referred to as **tyrosine kinase inhibitors** (TKIs). The most common TKIs currently prescribed are *imatinib mesylate* (Gleevec) and *dasatinib* (Sprycel). Table 38-1 lists the TKIs and their dosages, routes, uses, and considerations.

TABLE 38-1 TARGETED THERAPIES FOR CANCER TREATMENT

DRUG TYPE AND NAME	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Tyrosine Kinase Inhibitors (TKIs)		
dasatinib (Sprycel)	A: PO: 100-140 mg once in the morning and once in the evening, with or without a meal.	Approved for chronic myelogenous leukemia (CML) and acute lymphocytic leukemia (ALL). Do not crush or cut tablets; if tablets are crushed or broken, handle with gloves. If patient on antacids, administer 2 h before and 2 h after each dose; Avoid H_2 blockers and proton pump inhibitors (PPIs) Pregnancy category: D; PB: 95%; $t_{1/2}$: 3-5 h
imatinib mesylate (Gleevec)	For leukemia and myelodysplastic syndrome: A: PO: recommended starting dose is 400 mg/d for chronic phase and 600 mg/d for accelerated phase or blast crisis. Dose increases to max of 800 mg (given as 400 mg twice daily); can take with meal and large glass of water; drug can be dissolved in water or apple juice. For GIST: A: PO: recommended starting dose is 400 mg/d C >3 y: PO: 340 mg/m^2/d (not to exceed 600 mg/d) PO given as single daily dose, or dose may be divided and given once in morning and once in evening.	Approved for Philadelphia chromosome–positive CML, metastatic malignant GIST, ALL, and MDS. Avoid pregnancy and breastfeeding. Pregnancy category: D; PB: 95%; $t_{1/2}$: 18-40 h
Multikinase Inhibitors (MKIs)		
sorafenib (Nexavar)	A: PO 400 mg twice daily Administer orally without food (at least 1 h before or 2 h after meal).	Approved for hepatocellular cancer and advanced renal cell carcinoma. Pregnancy category: D; PB: 99.5%: $t_{1/2}$: 25-48 h
sunitinib (Sutent)	A: PO: 50 mg PO once daily on schedule of 4 wk on treatment followed by 2 wk off treatment. Administer orally with or without food.	Approved for GIST and advanced renal cell carcinoma (RCC). Pregnancy category: D; PB: 90%; $t_{1/2}$ of sunitinib is 40-60 h, and that of its major metabolite is 80-110 h.
Epidermal Growth Factor/Receptor Inhibitors (EGFRIs)		
cetuximab (Erbitux)	A: IV: initial infusion dose is 400 mg/m^2 IV over 2 h. Then continue weekly infusions of 250 mg/m^2 IV over 60 min.	Colorectal cancer and head and neck cancers. Administer only as an IV infusion with an infusion controller and never as a bolus or IV push. Administer with low-protein–binding 0.22-micron filter. Do not shake or further dilute vial. Do not mix with other drugs. Premedicate patient with H_1 antagonist (e.g., diphenhydramine 50 mg IV) 30-60 minutes before first dose. Pregnancy category: C; $t_{1/2}$: 41-214 h
erlotinib (Tarceva)	A: PO: 150 mg once daily Give drug on empty stomach, either 1 h before or 2 h after meal (administering with food increases risk for side effects). Administer at same time each day between meals	Approved for non–small-cell lung cancer (NSCLC) and pancreatic cancer. Pregnancy category: D; PB: 93%; $t_{1/2}$: 36 h
gefitinib (Iressa)	A: PO: 250 mg once daily Administer tablet with water without regard to meals.	Approved for NSCLC. Drug may be held for up to 14 d if poorly managed diarrhea occurs. Pregnancy category: D; PB: 90%; $t_{1/2}$: 48 h

TABLE 38-1 TARGETED THERAPIES FOR CANCER TREATMENT—cont'd

DRUG TYPE AND NAME	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
panitumumab (Vectibix)	A: IV: 6 mg/kg administered over 60 min given once every 2 wk	Approved for EGFR-expressing cancers: colorectal, lung, breast, bladder, pancreas, kidney, head and neck. Administer only as an IV infusion with an infusion controller and never as a bolus or IV push. Administer with low-protein– binding 0.2-micron or 0.22-micron in-line filter. Flush line with 0.9% sodium chloride injection before and after administration. Do not mix with other drugs or infusions. Instruct patient to avoid breastfeeding. Pregnancy category: C; t½: 7.5 d
trastuzumab (Herceptin)	A: IV: 4 mg/kg infused over 90 min on week 1. If patient tolerates initial infusion, starting at week 2 administer 2 mg/kg IV over at least 30 min once weekly	Approved for breast cancer that overexpresses *EGFR2* (HER2/neureceptor). Do not administer IV push or as bolus. Monitor patient for infusion-related reactions such as fever or chills, respiratory distress, or severe hypersensitivity reactions. Interrupt infusion if patient experiences dyspnea or significant hypotension. Pregnancy category: D; t½: 25 d
Vascular Endothelial Growth Factor/Receptor (VEGFR) Inhibitors		
bevacizumab (Avastin)	For metastatic breast cancer: A: IV: 10 mg/kg every 2 wk in combination with paclitaxel For colorectal cancer: A: IV: 5 mg/kg every 2 wk in combination with 5-fluorouracil–based chemotherapy. For non–small-cell lung cancer: A: IV: 15 mg/kg every 3 wk in combination with carboplatin and paclitaxel. For metastatic renal cell carcinoma: A: IV: 10 mg/kg IV every 2 weeks in combination with interferon alfa	Approved for metastatic breast cancer, colorectal cancer, NSCLC, and RCC. Administer only as an IV infusion with an infusion controller and never as a bolus or IV push. Administer IV over 90 min as infusion; if tolerated well, may administer second dose over 60 min. Mix infusions with only 0.9% sodium chloride and never with dextrose solutions. Discard any unused portion left in the vial, as product contains no preservatives. Pregnancy category: C; t½: 11-50 d
Proteasome Inhibitors		
bortezomib (Velcade)	For mantle cell lymphoma: 1.3 mg/m^2 IV bolus on days 1, 4, 8, and 11 followed by a 10-day rest period (days 12-21). For multiple myeloma: A: IV: Treatment administered for nine 6-wk cycles. In cycles 1-4, 1.3 mg/m^2/dose IV bolus given on days 1, 4, 8, and 11 followed by 10-d rest period (days 12-21) and again on days 22, 25, 29, and 32 followed by a 10-d rest period (days 33-42) in combination with melphalan and prednisone on days 1-4; this 6-wk cycle is considered one course.	Approved for mantle cell lymphoma (MCL) and multiple myeloma. At least 72 hours should elapse between consecutive doses of bortezomib (Velcade) to give normal cells time to recover. Administered as an IV injection bolus over 3-5 sec followed by saline flush Reconstitute for injection each vial with 3.5 mL of 0.9% sodium chloride for a final concentration of 1 mg/mL. Final product should be a clear, colorless, solution. Pregnancy category: D; PB: 83%: t½: 9-15 h

TABLE 38-1 TARGETED THERAPIES FOR CANCER TREATMENT—cont'd

DRUG TYPE AND NAME	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Angiogenesis Inhibitors		
temsirolimus (Torisel)	A: IV: 25 mg IV given over 30-60 min once a wk	Approved for advanced RCC. During preparation, protect drug from excessive room light and sunlight. Premedicate with diphenhydramine (Benadryl) 25-50 mg IV, or a similar antihistamine, approximately 30 min before the start of each dose. Two dilutions are required before IV infusion. Use only supplied diluent for initial dilution. Use an in-line polyethersulfone filter with pore size of ≤5 microns and an infusion pump. Administer only through polyethylene-lined administration sets. Administer dose over 30-60 min. Pregnancy category: D; t½: 17-20 d
Monoclonal Antibodies		
alemtuzumab (Campath)	A: IV: Start at 3 mg IV over 2 h once daily. When 3-mg dose is tolerated (infusion reactions grade 2 or less), escalate daily dose to 10 mg IV once daily and continue until infusion reactions are grade 2 or less, then start the maintenance dose of 30 mg IV given 3 times weekly on alternate days (e.g., Monday, Wednesday, Friday); total therapy duration including dose escalation is 12 wk.	Approved for chronic lymphocytic leukemia (CLL). Administer as an IV infusion with an infusion controller over 2 h and never as a bolus or IV push. Monitor patient closely for serious, sometimes fatal, infusion-related reactions. Premedicate 30 min before first dose, with any dose escalation, and as needed with diphenhydramine (Benadryl) (50 mg) and acetaminophen (Tylenol) (500-1000 mg). Withhold alemtuzumab (Campath) administration if a grade 3 or 4 infusion reaction occurs Pregnancy category: C; t½: 12 d
ibritumomab tiuxetan (Zevalin)	A: IV: Step 1: Rituximab 250 mg/m^2 IV is administered first (see rituximab monograph). Within 4 h of completing rituximab infusion, give 5 mCi (1.6 mg total antibody dose) of In-111 ibritumomab tiuxetan IV over 10 min. Step 2: Seven to nine d following step 1, give a second dose of rituximab 250 mg/m^2 IV. Within 4 h of completing the rituximab infusion, give Y-90 ibritumomab tiuxetan 0.4 mCi/kg (14.8 MBq/kg) or 0.3 mCi/kg (11.1 MBq/kg) IV over 10 min.	Approved for B-cell NHL. Use appropriate precautions for handling, preparing, and administering radiopharmaceuticals. Do not administer In-111 ibritumomab tiuxetan (Zevalin) and Y-90 ibritumomab tiuxetan unless rituximab (Rituxan) predose has been administered. Do not give Y-90 ibritumomab tiuxetan if platelet count <100,000/mm^3). Pregnancy category: D; t½: 30 h
rituximab (Rituxan)	A: IV: 375 mg/m^2 once weekly for 4 doses; may be retreated for additional 4 doses.	Relapsed or refractory, low-grade, or follicular CD20-positive B-cell NHL. Premedicate 30 min before administration with diphenhydramine (Benadryl) (50 mg), acetaminophen (Tylenol) 650-1000 mg (adults), and possibly corticosteroids. Do not administer as IV push or bolus. Administer first IV infusion at initial rate of 50 mg/h. If no hypersensitivity or infusion-related events, increase infusion rate in 50 mg/h increments every 30 min, to a maximum of 400 mg/h. Monitor patients closely during infusion for profound hypotension, dyspnea, and cardiovascular infusion–related reactions. Do not mix rituximab solution with other drugs. Pregnancy category: C; t½: 31.5-52.6 h

TABLE 38-1 TARGETED THERAPIES FOR CANCER TREATMENT—cont'd

DRUG TYPE AND NAME	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
I-131 tositumomab (Bexxar) (radioimmunotherapeutic agent)	A: IV: Step 1: Dosimetric step: On day 0, give 450 mg unlabeled tositumomab IV over 1 h followed by I-131 tositumomab 5 mCi (35 mg tositumomab) IV over 20 min. Total body gamma counts using a gamma camera obtained on day 0; day 2, 3, or 4; and day 6 or 7. Using these counts, perform calculations based on standard internal radiation dosimetry methods to determine patient-specific activity (in mCi) of radiolabeled tositumomab required to deliver maximum tolerated dose of 75 cGy total-body dose. Step 2: Therapeutic step: 450 mg unlabeled tositumomab IV over 1 h followed by patient-specific activity (in millicuries) iodine I-131 labeled to 35 mg of tositumomab IV between days 7 and 14.	Refractory CD20-positive, follicular NHL. Administer thyroid protection agents at least 24 h before step 1 and step 2. Do not administer to patients with known murine (mouse) hypersensitivity. Premedicate 30 min before administration with oral diphenhydramine (Benadryl) (50 mg) and acetaminophen (Tylenol) 650-1000 mg (adults). Use appropriate precautions for handling, preparing, and administering radiopharmaceuticals. Administer through IV tubing set with 0.22-micron in-line filter. Use same IV tubing set and filter throughout entire dosimetric or therapeutic step. Administer iodine I-131 tositumomab (Bexxar) infusion over 60 min. After infusion of iodine I-131 tositumomab (Bexxar) is complete, close stopcock to syringe. Flush extension set and secondary IV infusion set with 0.9% sodium chloride for injection. Pregnancy category: X; $t_{1/2}$: 8.5 d

d, Day; *GIST,* gastrointestinal stromal tumors; *mBq*, megabecquerels; *mCi*, millicuries; *MDS,* myelodysplastic syndrome, *h,* hour; *min,* minute; *wk,* week; ≤, less than or equal to.

Prototype Drug Chart 38-1 lists specific drug information about the TKI imatinib (Gleevec). Other approved TKIs include lapatinib (Tykerb), which is used with other drugs in the treatment of *HER2*-positive breast cancer.

TKIs exert their effects by directly inhibiting only specific types of tyrosine kinases. The types they inhibit are the SRC kinases, which are present in many cells (normal and cancerous) and a very specific type, the BCR-ABL tyrosine kinase. As shown in Figure 38-1, receptors on the cell membrane can activate tyrosine kinases, which then turn on signal transduction pathways promoting cell division. The TKIs are nonreceptor kinase inhibitors because they do not bind to the receptors on the plasma membrane. Instead they work directly on the tyrosine kinase molecule.

The SRC kinases are involved in the activation of signal transduction pathways promoting cell division in many cell types. The BCR-ABL tyrosine kinase is present only in cancer cells that have a specific gene mutation resulting from a chromosome structural rearrangement that forms a "Philadelphia chromosome." This mutation is highly present in chronic myelogenous leukemia (CML) cells and has been found in some other cancer cell types. When activated and expressed, BCR-ABL tyrosine kinase turns on a strong pro–cell-division signal transduction pathway that leads to proliferation of cancer cells. TKIs prevent activation of tyrosine kinases, which then inhibits further activation of the signal transduction pathway and stops the proliferation of cancer cells. This action can control the disease but cannot alone eradicate it.

Dasatinib

Dasatinib (Sprycel) is approved for chronic myelogenous leukemia (CML) and acute lymphocytic leukemia (ALL).

Pharmacokinetics Dasatinib is an oral drug that is readily absorbed from the gastrointestinal (GI) tract and can be taken with or without food. Antacids slow the absorption. The drug is extensively metabolized in the liver by the cytochrome P450 (CYP) 3A4 isoenzyme.

Pharmacodynamics Dasatinib most specifically targets BCR-ABL tyrosine kinase, found in CML cells. The drug blocks the ATP (adenosine triphosphase) binding site on the tyrosine kinase so that it does not become activated. This lack of BCR-ABL tyrosine kinase activation inhibits further activation of the signal transduction pathway and stops the proliferation of cancer cells. The drug has the greatest effects on cancer cells expressing the Philadelphia chromosome genetic mutation.

Side Effects and Adverse Reactions. Dasatinib often causes electrolyte imbalances, especially low serum levels of phosphorus and calcium. These imbalances may require phosphorus and calcium replacement. ECG abnormalities, especially prolonged QT interval, have been seen in patients taking dasatinib. This drug should be used cautiously in anyone at risk for long QT, such as those who have hypokalemia or hypomagnesemia and those with a family history of long QT syndrome. Fluid retention has also been seen in up to 50% of patients. Hematologic side effects of myelosuppression with anemia, thrombocytopenia, and neutropenia are relatively common.

Drug Interactions. CYP3A4 enzyme inhibitors decrease dasatinib metabolism, resulting in an increased serum concentration and increased risk for toxicity. Other drugs that

PROTOTYPE DRUG CHART 38-1

Imatinib Mesylate

Drug Class

Tyrosine kinase inhibitor
Trade Name: Gleevec
Pregnancy Category: D

Dosage

Leukemias; myelodysplastic syndrome; GIST: A: PO: Recommended starting dose is 400 mg/d for chronic phase and 600 mg/d for accelerated phase or blast crisis. Dose increases to max of 800 mg (given as 400 mg twice daily); C >3 y: PO: 260 mg/m^2/day PO given as a single daily dose, or the dose may be divided given once in the morning and once in the evening.

Contraindications

Patients who may become pregnant, are pregnant, or are breastfeeding; have severe heart failure or severe kidney disease; have moderate to severe liver disease and are also taking another hepatotoxic chemotherapy drug(s); or have severe neutropenia, anemia, or thrombocytopenia

Drug-Lab-Food Interactions

Drug: Any agent that inhibits cytochrome P450 (CYP) 3A4 may decrease the metabolism of imatinib and increase imatinib concentrations leading to an increased incidence of adverse reactions (examples include ketoconazole, amiodarone, antiretroviral protease inhibitors, dalfopristin quinupristin, and mifepristone).

Any drug that induces cytochrome P450 (CYP) 3A4 may increase the metabolism of imatinib and decrease imatinib concentrations and clinical effects (examples include barbiturates, bosentan, carbamazepine, dexamethasone, phenobarbital, rifabutin, and rifapentine).

Any drug that is metabolized by cytochrome P450 (CYP) 2D6 may have higher than normal blood levels of the drug (examples include amoxapine, atomoxetine, carvedilol, metoprolol, propranolol, timolol, clozapine, codeine, cyclobenzaprine, darifenacin, fenfluramine, dexfenfluramine, dextromethorphan, flecainide, haloperidol, hydrocodone, maprotiline, methadone, methamphetamine, mexiletine, morphine, oxycodone, paroxetine, perphenazine, propafenone, risperidone, thioridazine, tramadol, trazodone, tricyclic antidepressants, and venlafaxine).

St. John's wort decreases imatinib blood levels and may decrease its effectiveness.

Taking imatinib with acetaminophen increases the risk for acetaminophen poisoning.

Taking imatinib with NSAIDs increases hypertension and disruption of platelet aggregation.

Taking imatinib with warfarin increases the risk for severe bleeding.

Lab: May alter liver enzyme levels and bilirubin levels.

Food: Grapefruit juice increases imatinib plasma concentrations.

Pharmacokinetics

Absorption: Bioavailability is 98%. Steady-state levels achieved in 1-2 days.

Distribution: 95% PB with extensive distribution

Metabolism: Metabolized mainly in the liver by the cytochrome P450 (CYP) 3A4 and CYP2D6 isoenzymes; t½ of drug is 18 hours, of its major metabolite 40 hours.

Excretion: Mainly in the feces

Pharmacodynamics

Oral absorption is fast and not affected by meal timing. Can take with meal and large glass of water; drug can be dissolved in water or apple juice.

Therapeutic Effects/Uses

Approved for leukemia, GIST, and MDS

Mode of Action: Imatinib competitively inhibits the ATP binding site on tyrosine kinases specific for Abl, PDGF, SCF, and c-Kit, preventing the activation of those specific tyrosine kinases. This action inhibits platelet-derived growth factor (PDGF) and stem cell factor (SCF) mediated cellular events. This leads to reduced cancer cell division and induction of apoptosis. This action results in blockage of downstream EGFR-TK mediated signal transduction pathways, cell cycle arrest, and inhibition of angiogenesis.

Side Effects

Edema, fluid retention, GI irritation, nausea, vomiting, neutropenia, thrombocytopenia, and hepatotoxicity

Adverse Reactions

Allergic reactions, severe neutropenia increasing the risk for infection, severe thrombocytopenia increasing the risk for excessive bleeding/hemorrhage, liver impairment, kidney impairment.

A, Adult; *GIST,* gastrointestinal stromal tumors; *MDS,* myelodysplastic syndrome, *PB,* protein-binding; *PO,* by mouth; *t ½,* half-life; *y,* year; *>,* greater than.

strongly increase the serum concentration of dasatinib include atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, triazolobenzodiazepines, and voriconazole.

Drugs that enhance the activity of the CYP3A4 enzyme decrease dasatinib serum levels and reduce its effectiveness. Such drugs include aminoglutethimide, barbiturates, carbamazepine, dexamethasone, griseofulvin, modafinil, nafcillin, phenytoin, primidone, rifabutin, and rifampin. Other drugs that appear to reduce the effectiveness of dasatinib include antacids, H_2 blockers, and proton pump inhibitors.

Dasatinib may interfere with the metabolism of other drugs that use the CYP3A4 enzyme system, such as alfentanil, astemizole, terfenadine, cisapride, cyclosporine, fentanyl, pimozide, quinidine, sirolimus, tacrolimus, and ergot alkaloids.

Multikinase Inhibitors

The **multikinase inhibitors** (MKIs) are chemicals that directly inhibit the activity of specific kinases in cancer cells and in cancer cell vasculature. (Recall that kinases are enzymes that activate other proteins, including those that activate signal transduction pathways promoting cancer cell division.) Table 38-1 lists the MKIs and their dosages, routes, uses, and considerations.

Sorafenib

Sorafenib (Nexavar) is a multikinase inhibitor that specifically targets serine/threonine and receptor tyrosine kinases, which are activated as a result of gene mutations and are most commonly found in pancreatic cancer, colon cancer, and non–small-cell lung cancer. In addition, the drug may be used in those hepatocellular carcinomas and renal cell carcinomas that overexpress the target.

Pharmacokinetics Sorafenib (Nexavar) is an oral drug whose absorption and bioavailability are inhibited when taken with a high-fat meal. The drug is metabolized in the liver, mainly by the CYP3A4 enzyme system. It is 99.5% protein-bound and reaches peak plasma level in about 3 hours. The drug is eliminated in the feces and urine, with a half-life of 25 to 48 hours.

Pharmacodynamics Sorafenib inhibits Raf kinase, vascular endothelial growth factor (VEGF) receptors VEGFR-2 and VEGFR-3, platelet-derived growth factor receptor (PDGFR), Kit receptor tyrosine kinase (KIT), fms-like tyrosine kinase 3 (FLT-3), and RET. When cytokines or growth factors activate these tyrosine kinase receptors, a protein-kinase–mediated cascade starts, leading to uncontrolled cellular proliferation. The inhibition of these signaling pathways by sorafenib results in decreased cancer cellular proliferation. In addition, sorafenib specifically inhibits two VEGF receptors (VEGFR-2 and VEGFR-3), which are key receptor tyrosine kinases involved in angiogenesis. This action results in reduced blood vessel formation in cancer cells. This anticancer activity is present only when the drug is present, and cancer growth returns when therapy is completed.

Side Effects and Adverse Reactions. Sorafenib has many common side effects. Hypertension is very common and can occur within the first 6 weeks of therapy. Skin side effects include alopecia, pruritus, dry skin, exfoliative dermatitis, acne, flushing, and palmar-plantar erythrodysesthesia (hand-foot syndrome), which also manifest within the first 6 weeks. Other side effects include weight loss, nausea/vomiting, diarrhea, anorexia, constipation, abdominal pain, mucositis, dyspepsia, dysphagia, and mild neutropenia and thrombocytopenia. More severe effects are possible, including pancreatitis, erectile dysfunction, and myocardial ischemia.

Drug Interactions. Sorafenib levels are not increased by the presence of other drugs, even those that inhibit the enzyme that metabolizes sorefenib. However, drugs that induce metabolizing enzyme activity can reduce the blood levels and effectiveness of sorafenib. These include rifampin, phenytoin, phenobarbital, carbamazepine, dexamethasone, rifabutin, and rifapenten.

Sorafenib can increase the blood levels of rapaglinide, amiodarone, ibuprofen, loperamide, irinotecan, propofol, and warfarin.

Sunitinib

Sunitinib (Sutent) inhibits more than 80 tyrosine kinases. This inhibition results in regression of tumor growth, especially in clear cell renal cell carcinoma (RCC) and gastrointestinal stromal tumors (GIST).

Pharmacokinetics Sunitinib is an oral drug that is well absorbed with or without meals. It is 90% protein-bound and reaches peak plasma levels in 6 to 12 hours. The drug is metabolized in the liver, mainly by the CYP3A4 enzyme system, and is eliminated in the feces. The half-life of sunitinib is 40 to 60 hours, and its major active metabolite has a half-life of 80 to 110 hours.

Pharmacodynamics The action of sunitinib is the inhibition of many receptor tyrosine kinases (RTKs), including those of platelet-derived growth factor receptors (PDGFR), vascular endothelial growth factor receptors (VEGFR1, VEGFR2, VEGFR3), and a variety of others. This inhibition results in decreased cancer cell proliferation and in reduced blood vessel formation in cancer cells. This drug also increases adverse effects on normal tissues, especially hair and skin.

Side Effects and Adverse Reactions. Side effects and adverse reactions are more widespread as a result of the number of different types of kinases sunitinib inhibits. Cardiovascular effects include hypertension, peripheral edema, left ventricular dysfunction, prolonged QT interval, and venous thromboembolism. GI effects include nausea/vomiting, diarrhea, stomatitis, and dyspepsia. Neuromuscular effects include fatigue, asthenia, headache, dizziness, peripheral neuropathy, mild arthralgia, limb pain, myalgia, and back pain. Liver impairment may occur with elevated liver enzyme levels and jaundice of the skin and sclera. Common integumentary changes include depigmentation of the skin, skin discoloration, rash, dry skin, and palmar-plantar erythrodysesthesia. Endocrine changes may include hypothyroidism and adrenal insufficiency. Hematologic changes may include myelosuppression. Respiratory-associated effects may include mild dyspnea and cough.

Drug Interactions. Sunitinib's blood levels and activity are increased by drugs that inhibit CYP3A4 enzyme levels, including atazanavir, clarithromycin, ketoconazole, itraconazole, indinavir, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, voriconazole, diltiazem, and verapamil. When these drugs are used during sunitinib therapy, side effects of sunitinib are more common and more severe. Drugs that increase sunitinib elimination and reduce its effectiveness include rifampin, phenytoin, phenobarbital, carbamazepine, dexamethasone, rifabutin, and rifapentin.

Epidermal Growth Factor/Receptor Inhibitors

The epidermal growth factor/receptor inhibitors (EGFRIs) include erlotinib, gefitinib, panitumumab, and cetuximab. Most EGFRIs ultimately also inhibit tyrosine kinase, but they do it more indirectly than the TKIs. As shown in Figure 38-1, the growth factor receptors on the cell membrane can activate tyrosine kinases, which then turn on signal transduction pathways promoting cell division. The EGFRIs bind to different areas of the epidermal growth factor receptor, blocking its activity so that it cannot activate tyrosine kinase. As a result, the downstream signal transduction pathway for promotion of cell division is inhibited and cell proliferation is severely limited. Table 38-1 lists the EGFRIs and their dosages, routes, uses, and considerations. Prototype Drug Chart 38-2 lists the specific drug information for erlotinib (Tarceva).

Nursing Process
Patient-Centered Collaborative Care

Tyrosine Kinase Inhibitors and Multikinase Inhibitors for Cancer Treatment

Assessment

- Conduct a detailed medication history, including a list of all concurrent medications, including prescriptions, over-the-counter medicines, antacids, dietary supplements, vitamins, and herbal supplements to avoid drug-drug interactions.
- Obtain baseline information about patient's physical status before initiating targeted therapy regimen and during treatment period. Include height, weight, vital signs, and laboratory values (complete blood count [CBC], uric acid, electrolytes, hepatic and renal studies, cardiopulmonary assessment, intake and output).

PROTOTYPE DRUG CHART 38-2

Erlotinib

Drug Class	Dosage
Epidermal growth factor/receptor inhibitor Trade Name: Tarceva Pregnancy Category: D	For non–small-cell lung cancer and pancreatic cancer: A: PO: 150 mg once daily
Contraindications	**Drug-Lab-Food Interactions**
Patients who may become pregnant, are pregnant, or are breastfeeding; have preexisting respiratory problems (pulmonary fibrosis may occur); or are dehydrated or have liver impairment (risk for renal failure is high). Use cautiously in patients with history of peptic ulcer disease or diverticulitis (increases risk for GI perforation).	Drug: Drugs that increase blood levels of erlotinib and may lead to increased adverse reactions or toxicities include ketoconazole, atazanavir, clarithromycin, indinavir, itraconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, troleandomycin (TAO), and voriconazole. Drugs that reduce effectiveness of erlotinib include rifampicin, rifabutin, rifapentine, phenytoin, carbamazepine, phenobarbital, H_2 blockers, and proton pump inhibitors. Lab: Erlotinib may increase INR and lead to increased risk for bleeding. Food: Grapefruit juice increases erlotinib levels and increases the risk for adverse effects. St. John's wort decreases erlotinib levels and reduces its effectiveness. Cigarette smoking also decreases erlotinib levels.
Pharmacokinetics	**Pharmacodynamics**
Absorption: Bioavailability is 60%. Distribution: 93% PB. Steady-state levels are achieved in 7-8 d. Metabolism: Liver (CYP3A4 and CYP1A2 enzymes) Excretion: Mainly in feces	Give drug on an empty stomach, either 1 h before or 2 h after meal (administering with food increases risk for side effects). Administer at same time each day between meals. Oral absorption is moderately fast and is enhanced with food intake. High gastric pH levels inhibit oral absorption.
Therapeutic Effects/Uses	
Approved for treatment of non–small-cell lung cancer (NSCLC) and pancreatic cancer. Mode of Action: Erlotinib selectively inhibits activation of epidermal growth factor receptor-tyrosine kinase (EGFR-TK).	
Side Effects	**Adverse Reactions**
Diarrhea and skin reactions	Ocular changes (inflammation, corneal perforation), GI perforation, skin desquamation, renal failure, hepatic failure.

A, Adult; *d,* day; *h,* hour; *PB,* protein-binding; *PO,* by mouth.

- Assess laboratory studies, including CBC with differential, hepatic and renal studies, electrolytes, and urinalysis at the beginning of therapy and at specified time intervals (ranging from weekly to monthly) during therapy.
- Assess patient and family knowledge related to therapeutic regimen.

Nursing Diagnoses

- Deficient knowledge related to targeted therapy regimen
- Risk for impaired skin integrity related to dermatologic effects and toxicities of therapy
- Risk for infection related to bone marrow suppression
- Risk for deficient fluid volume related to GI effects of therapy
- Risk for electrolyte imbalance related to actions of targeted therapy

Planning

- Patient/family/caregiver will verbalize understanding of targeted therapy as part of an anticancer treatment regimen.
- Patient/family/caregiver will demonstrate understanding of importance of reporting targeted therapy–related side effects and adverse reactions.
- Patient/family/caregiver will verbalize strategies to minimize risks related to targeted therapy–related side effects.
- Patient's side effects will be managed to a level that the patient can tolerate and are not life threatening.
- Patient will remain infection-free.
- Patient's fluid balance and electrolytes are maintained at expected normal ranges.

Nursing Interventions

- Monitor complete blood cell count with differential and platelet count at baseline, once weekly for the first month, every other week for the second month, and at least every 2 to 3 months thereafter.
- Monitor electrolytes regularly during treatment and for 8 weeks after treatment is discontinued, especially phosphorus and calcium levels, because low levels may require replacement.
- Monitor liver function and renal function tests at baseline and at least once monthly during therapy.
- Monitor blood pressure at baseline and at least weekly during therapy.
- Monitor ejection fraction at baseline and periodically during therapy.
- Monitor thyroid function if patient experiences symptoms of hypothyroidism (cold intolerance, hair loss, decreased memory or mental alertness, constipation, bradycardia).
- Monitor adrenal function in patients receiving sunitinib who are exposed to stress (e.g., surgery, shock, trauma, infections).
- Monitor hands and feet for signs of palmar-plantar erythrodysesthesia (redness, pain, swelling or blisters).
- Follow agency policy for safe handling, preparing, administering, and dispensing of targeted therapy agents.
- Administer prescribed premedications according to established protocols for specific targeted therapies.
- Discontinue therapy before elective surgery.
- Sorafenib potentiates the activity of warfarin. Check the patient's INR weekly.

Patient Teaching

- Teach patients to take imatinib with food or with at least 240 mL of water to reduce gastric irritation.
- Teach patients to weigh themselves daily and report a weight gain of more than 2 pounds in 1 day or 4 pounds in 1 week to the health care provider.
- Teach patients to check hands and feet daily for signs of palmar-plantar erythrodysesthesia (redness, pain, swelling, or blisters) and to report these symptoms when they appear.
- Avoid alcohol and nonessential drugs that are cleared by the liver or have liver-toxic effects (e.g., acetaminophen).
- Report symptoms of adverse effects or severe side effects promptly, especially fever, chills, persistent sore throat, swelling, weight gain, or increasing shortness of breath.
- Report symptoms of bleeding immediately, including black stools, emesis that looks like coffee grounds, or easy bleeding/bruising.
- Report symptoms of liver impairment immediately, including stomach/abdominal pain, yellowing of eyes or skin, dark urine, or unusual fatigue.
- Remind women with childbearing potential to avoid pregnancy throughout treatment and for up to 12 months after treatment is completed.
- Advise breastfeeding patients to stop breastfeeding during and for 60 days after therapy.
- Teach patients that drinking grapefruit juice can increase blood levels of most targeted therapy drugs and worsen side effects or adverse effects. Encourage patient to avoid grapefruit juice while receiving targeted therapies.
- Teach patients to avoid using the herbal St. John's wort while receiving treatment with targeted therapies because this agent decreases the effectiveness of most of these drugs.
- Remind patients receiving sorafenib who also take warfarin to keep all appointments for INR testing.

Evaluation

- Patient/family/caregiver education needs are met.
- Patient/family/caregiver understands therapy-related side effects/adverse reactions.

- Patient/family/caregiver understands strategies to minimize side effects/adverse reactions.
- Side effects are managed effectively.
- Patient is free from infection.
- Patient's fluid balance and electrolytes are maintained at expected normal ranges.

Some epidermal growth factor/receptor inhibitors carry a boxed warning for adverse effects. A boxed warning indicates that the FDA has provided notice that a drug may produce serious or even life-threatening effects in some people in addition to its beneficial effects. This warning is printed on the package insert sheet and is bordered in black. Drugs with this warning can still be used, but prescribers are instructed to make certain that such drugs are prescribed only for patients who meet strict criteria and who understand the serious nature of the possible adverse effects.

Gefitinib

Gefitinib (Iressa) is a synthetic anilinoquinazoline that selectively inhibits the epidermal growth factor receptor–tyrosine kinase (EGFR-TK). It is most commonly used in the management of locally or advanced metastatic non–small-cell lung cancer.

Pharmacokinetics Gefitinib is absorbed slowly in the gastrointestinal tract, with 60% reaching systemic circulation. It is metabolized mainly in the liver by the CP3A4 enzyme and is primarily excreted in the feces. The half-life is 48 hours.

Pharmacodynamics Gefitinib selectively inhibits EGFR-TK. This action results in blockage of downstream EGFR-TK–mediated signal transduction pathways, cell cycle arrest, and inhibition of angiogenesis.

Side Effects and Adverse Reactions. Gefitinib can cause conjunctivitis and abnormal eyelash growth. Rash occurs in about 43% of patients. Some patients experience a moderate to low potential for nausea/vomiting and diarrhea. Patients can also experience acne, pruritus, anorexia, and an increase in hepatic transaminases.

Drug Interactions. Gefitinib activity is affected by CYP3A4 enzyme inhibitors, which decrease dasatinib metabolism, resulting in an increased serum concentration and increased risk for toxicity. These drugs include atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, and voriconazole. Drugs that lower gefitinib serum levels and reduce its activity include carbamazepine, phenytoin, phenobarbital, rifabutin, and rifampin. Because gefitinib works best in an acid environment, its activity is reduced with the use of H_2 histamine blockers and proton pump inhibitors. When this drug is received by patients on warfarin therapy, the effectiveness of warfarin (Coumadin) is greatly increased and bleeding risks are increased. The dosage of warfarin should be adjusted based on INR results.

Panitumumab

Panitumumab (Vectibex) is a fully humanized monoclonal antibody (Table 38-2). (Refer to the Monoclonal Antibodies section later in this chapter for a more complete description of antibody types.) It is most commonly used in the management of advanced metastatic colorectal carcinomas that express or overexpress EGFR.

TABLE 38-2 SUFFIXES OF TARGETED CANCER THERAPIES

SUFFIX	MEANING
mab	A monoclonal antibody
momab	Composed of only murine (mouse) proteins
imab	Composed of more human proteins (>60%) than murine proteins (~30%)
zumab	Composed of mostly human proteins (95% or more) and only a few murine proteins (<5%)
umab	Composed of only human proteins and no murine proteins
inib	A tyrosine kinase inhibitor
zomib	A proteasome inhibitor

Pharmacokinetics Panitumumab is administered as an intravenous infusion. It is a small immunoglobulin that appears to be eliminated in the feces. The half-life is 7.5 days.

Pharmacodynamics Panitumumab binds strongly to the EGFR when it is overexpressed on malignant cells. It binds specifically to the EGFR on both normal and tumor cells, and prevents formation of a ligand (arm) that usually attaches epidermal growth factor to the receptor. As a result, EGFR-TKs are not activated and the signals are not conducted downstream. Other effects of this drug also include inhibition of cell growth, induction of apoptosis, and decreased proinflammatory cytokine and vascular growth factor production. In addition, binding of panitumumab to the EGFR causes the receptor to be taken into the cell, preventing it from binding to agonists that activate the receptor. Tumors must express EGFR for patients to be candidates for panitumumab.

Side Effects and Adverse Reactions. Panitumumab carries a boxed warning for dermatologic problems and toxicity. Manifestations usually occur within the first 2 weeks of therapy and include erythema, acneform rash, pruritus, exfoliation, rash, skin fissures, acne, dry skin, and paronychia and other nail disorders. Electrolyte imbalances (specifically hypomagnesemia and hypocalcemia) may occur and require replacement. Severe diarrhea can occur when panitumumab is given along with irinotecan. Severe infusion reactions, including angioedema and anaphylaxis, have occurred with hypotension and bronchospasm. Although this reaction is rare, patients should be monitored closely throughout the infusion.

Drug Interactions. This drug has not been shown to be associated with general drug interactions. However, when administered with other EGFRIs, side effects and toxicities are additive and more severe. Panitumumab is not recommended for use in combination with other antineoplastic drug regimens.

Cetuximab

Cetuximab (Erbitux) is a partially humanized monoclonal antibody (see Table 38-2). (Refer to the Monoclonal Antibodies section later in this chapter for a more complete description of antibody types.) It is most commonly used for the management of colorectal and head and neck cancers.

Pharmacokinetics Cetuximab is administered as an intravenous infusion. Steady-state concentration occurs by the third weekly infusion. The half-life is long, ranging from 41 to 213 hours, with a mean of 97 hours.

Pharmacodynamics Cetuximab still contains about 30% mouse proteins. It binds specifically to EGFR on both normal and tumor cells and prevents formation of a ligand that usually attaches epidermal growth factor to the receptor. This action prevents the receptor from binding to agonists that activate it. As a result, EGFR-TKs are not activated and the signals are not conducted downstream. Other effects of this drug also include inhibition of cell growth, induction of apoptosis, decreased proinflammatory cytokine and vascular growth factor production, and internalization of the EGFR. Cetuximab may make cancer cells more vulnerable to other cancer chemotherapy agents and radiation therapy. The drug is most effective in causing regression in tumors that have the wild-type *K-RAS* oncogene and overexpress EGFR.

Side Effects and Adverse Reactions. Cetuximab carries a boxed warning for infusion reactions, usually with the initial dosing, although severe reactions also have been reported during later infusions. Manifestations include rapid onset of airway obstruction, including bronchospasm, stridor, hoarseness, urticaria, and hypotension. Cetuximab is associated with dermatologic changes that typically involve the face, upper chest, and back. An acneform rash occurs in 90% of patients, usually within the first 2 weeks of therapy. Most patients continue to have the rash for at least 28 days after therapy is discontinued.

Drug Interactions. This drug has not been shown to be associated with general drug interactions. However, when administered with other EGFRIs, side effects and toxicities are additive and more severe.

Trastuzumab

Trastuzumab (Herceptin) is a monoclonal antibody that binds to the HER2 protein on the surface of cancer cells that overexpress this receptor. The HER2 receptor is structurally related to the EGFR. The HER2 receptor is overexpressed in some breast, ovarian, and colon cancers. When this receptor is overexpressed, there is increased cancer cell proliferation and increased angiogenesis. Trastuzumab is most commonly used in combination with chemotherapy agents to manage breast, ovarian, and colorectal cancers that have demonstrated overexpression of the HER2 receptor.

Pharmacokinetics Trastuzumab is administered as a weekly intravenous infusion. Its half-life averages 25 days, but it may be present in the blood for as long as 18 weeks after therapy is discontinued. Just like most monoclonal antibodies, trastuzumab appears to be eliminated slowly through the feces.

Pharmacodynamics Trastuzumab is a mostly humanized monoclonal antibody that binds to the HER2 protein on the surface of breast, ovarian, and colon cancer cells that overexpress this receptor. This drug specifically inhibits the proliferation of cancer cells that overexpress HER2 receptors. In addition, binding of trastuzumab to the cancer cell receptor increases killing of these cells through attack by immune system cells, especially natural killer cells and monocytes.

Side Effects and Adverse Reactions. Trastuzumab carries a boxed warning for cardiomyopathy manifesting as congestive heart failure when the drug is used as monotherapy. This risk is increased when the drug is given in combination with other drugs that cause cardiotoxicity, such as the anthracyclines and cyclophosphamide. Hypersensitivity reactions, including anaphylaxis, may occur but are not common. Trastuzumab is associated with headache, dizziness, hypotension, fever, chills, and nausea during the initial infusion. After the initial infusion, these symptoms typically usually do not recur. Other common side effects include headache, muscle aches, and loss of appetite.

Drug Interactions. Trastuzumab can increase the incidence and severity of cardiac dysfunction in patients who receive trastuzumab in combination with anthracyclines and cyclophosphamide. This drug may increase myelosuppressive effects of other antineoplastic agents.

Vascular Endothelial Growth Factor/Receptor Inhibitors

Bevacizumab

Bevacizumab (Avastin) is a humanized monoclonal antibody (see Table 38-1). It binds to vascular endothelial growth factor (VEGF) and prevents the binding of VEGF with its receptors, VEGFR-1 (Flt-1) and VEGFR-2 (Flk-1/KDR), which are found on the surface of endothelial cells. The role of VEGF is critical in angiogenesis, the formation of new blood vessels. In human cancers, increased VEGF expression is associated with increased microvascular density, tumor growth, metastasis, and poor prognosis. The result of bevacizumab therapy is the reduction of microvascular growth and inhibition of metastatic disease progression. Bevacizumab is approved for many types of malignancies, all in combination with chemotherapy.

Pharmacokinetics Bevacizumab is administered as an intravenous infusion, usually every 2 to 3 weeks. The half-life is about 20 days (range of 11 to 50 days) and steady-state levels are achieved in about 100 days. Clearance varies with weight, gender, and tumor burden, with men clearing the drug faster than women.

Pharmacodynamics Bevacizumab binds to the vascular endothelial growth factor receptor (VEGFR) on tumors that overexpress this receptor. The result of this binding is the competitive inhibition of vascular endothelial growth factor with the VEGFR. This action leads to reduced tumor vascularity, the development of tumor necrosis, and reduced metastatic potential.

Side Effects and Adverse Reactions. Bevacizumab carries a boxed warning for GI perforations, wound dehiscence, impaired wound healing, hemorrhage, and fistula formation after surgery. Thus, the drug should not be given within 28 days after major surgery. Hypertension is a common side effect of bevacizumab. Other side effects are associated with hematopoietic suppression, including neutropenia and thrombocytopenia. Proteinuria can be seen in about 36% of patients, and nephrotic syndrome has developed in rare situations. The risk for thromboembolism and deep vein thrombosis is increased among patients taking the drug for colon cancer and non–small-cell lung cancer.

Drug Interactions. No specific drug interactions have been reported with bevacizumab; however, coadministration of drugs with similar pharmacologic effects, especially traditional chemotherapy agents, may cause additive pharmacologic effects, including toxicity.

Nursing Process
Patient-Centered Collaborative Care

Epidermal Growth Factor/Receptor Inhibitors and Vascular Endothelial Growth Factor/Receptor Inhibitors for Cancer Treatment

Assessment

- Conduct a detailed medication history, including a list of all concurrent medications, including prescriptions, over-the counter medicines, antacids, dietary supplements, vitamins, and herbal supplements to avoid drug-drug interactions.
- Obtain baseline information about patient's physical status before initiating targeted therapy and during the treatment period. Include height, weight, vital signs, and laboratory values (CBC, uric acid, electrolytes, hepatic and renal studies, cardiopulmonary assessment, intake and output).
- Assess laboratory studies, including CBC with differential, hepatic and renal studies, electrolytes, and urinalysis at the beginning of therapy and at specified time intervals (ranging from weekly to monthly) during therapy.
- Conduct a detailed medication history, including a list of all concurrent medications, including prescriptions, over-the-counter medicines, antacids, dietary supplements, vitamins, and herbal supplements to avoid drug-drug interactions.
- Assess patient/family/caregiver knowledge related to therapeutic regimen.

Nursing Diagnoses

- Deficient knowledge related to targeted therapy regimen
- Risk for impaired skin integrity related to dermatologic effects and toxicities of therapy
- Risk for infection related to bone marrow suppression
- Risk for deficient fluid volume related to GI effects of therapy
- Risk for electrolyte imbalance related to actions of targeted therapy

Planning

- Patient and family will verbalize understanding of targeted therapy as part of an anticancer treatment regimen.
- Patient and family will demonstrate understanding of the importance of reporting targeted therapy–related side effects and adverse reactions.
- Patient and family will verbalize strategies to minimize risks related to targeted therapy–related side effects.
- Patient's side effects will be managed to a tolerable level and are not life-threatening.
- Patient will remain free from infection.
- Patient's fluid balance and electrolytes are maintained at expected normal ranges.

Nursing Interventions

- When administering monoclonal antibodies intravenously, have resuscitation equipment nearby, and stay with the patient during the first 15 minutes of the infusion. Thereafter, monitor vital signs every 15 to 30 minutes during the infusion and for 1 hour after infusion is complete.
- Examine patient's skin closely at each visit for the presence of erythema, rash, peeling, or blister formation, and rate the severity of dermatologic reactions. Also determine whether infection is present in any nonintact skin.
- Monitor electrolytes regularly during treatment and for 8 weeks after treatment is discontinued, especially phosphorus and calcium levels, because low levels may require replacement.
- Assess lower extremities for deep vein thrombosis at every visit.
- Monitor renal function tests at baseline and at least once monthly during therapy.
- Monitor complete blood cell count with differential and platelet count at baseline, and as often as recommended for specific agents.
- Administer prescribed premedications according to established protocols for specific targeted therapies.
- Follow agency policy for safe handling, preparing, administering, and dispensing targeted therapy agents.
- Gefitinib potentiates the activity of warfarin. Check the patient's INR weekly.
- Before administering trastuzumab, ask whether the patient has a known allergy to hamsters or hamster products.
- With trastuzumab therapy, monitor electrocardiogram and ejection fraction at baseline and periodically during treatment.
- Use with caution in patients older than 65 years of age because the incidence of serious adverse events is higher among older adults.
- Monitor blood pressure at least every 2 to 3 weeks during therapy. Monitor more frequently if hypertension develops.
- Monitor for proteinuria with a urine dipstick before each dose. Patients with a 2+ or greater reading should undergo further assessment, such as 24-hour urine collection.
- Initiate bevacizumab therapy at least 28 days after major surgery or when the surgical incision is completely healed, whichever occurs later. Consider discontinuing bevacizumab before elective surgery or delaying the surgery until 2 months after therapy is discontinued.

Patient Teaching

- Advise patients to seek medical help immediately if chest pain, symptoms of stroke (e.g., change in mental awareness; inability to talk or move one side of the body; sudden numbness or weakness of the face, arm, or leg; seizures), severe abdominal pain, or swelling associated with redness or pain in one leg occurs.
- Report symptoms of adverse effects or severe side effects promptly, especially fever, chills, persistent sore throat, swelling, weight gain, or increasing shortness of breath.
- Report symptoms of bleeding immediately, including black stools, vomit that looks like coffee grounds, and easy bleeding/bruising.
- Advise patients taking erlotinib to immediately report worsening of skin rash; severe or persistent diarrhea, nausea, anorexia, or vomiting; onset or worsening of unexplained shortness of breath or cough; or eye irritation.
- Teach patients to weigh themselves daily and report a weight gain of more than 2 pounds in 1 day or 4 pounds in 1 week to the health care provider.
- Advise patients to notify the health care provider if foaming of urine occurs (an indication of protein in the urine).
- Teach patients to avoid taking NSAIDs, such as aspirin (except for low-dose aspirin), celecoxib (Celebrex), ibuprofen (Advil, Motrin), and naproxen (Aleve), to prevent excessive bleeding.
- Teach patients receiving bevacizumab ways to promote venous return and avoid deep vein thrombosis (DVT), such as avoiding becoming dehydrated, not wearing clothing that restricts circulation, and avoiding smoking cigarettes.
- Remind women with childbearing potential to avoid pregnancy throughout treatment and for up to 12 months after treatment is completed.
- Advise breastfeeding women to stop breastfeeding during and for 60 days after therapy.
- Teach patients to avoid direct sunlight and tanning beds to prevent worsening of skin side effects.
- Teach patients to avoid cigarette smoking while taking erlotinib.
- Remind patients taking gefitinib who also take warfarin (Coumadin) to keep all appointments for INR testing.

Evaluation

- Patient/family/caregiver education needs are met.
- Patient/family/caregiver understands therapy-related side effects/adverse reactions.
- Patient/family/caregiver understands strategies to minimize side effects/adverse reactions.
- Side effects are managed effectively.
- Patient is free from infection.
- Patient's fluid balance and electrolytes are maintained at expected normal ranges.

Proteasome Inhibitors

Bortezomib

Bortezomib (Velcade) works by inhibiting the 26S proteasome, which is part of the most common proteasome pathway (see Table 38-1). A **proteasome** is a large complex of proteins in cell fluid (cytoplasm) and cell nucleus that regulates protein expression and the degradation of damaged or old proteins within the cell. Its activity is critical to activation or suppression of cellular functions. This system regulates the expression of substances that mediate cell cycle progression (especially oncogene products and cyclins), suppressor genes (especially the *Tp53* gene), and proteins that signal apoptosis. When proteasomes are inhibited, cells are much more likely to undergo apoptosis. Although proteasomes are present in normal and cancer cells, the cancer cells are much more sensitive to the effects of proteasome inhibition than normal cells. Thus, proteasome inhibition results in suppression of cancer cell division and enhancement of cancer cell apoptosis. Bortezomib is most commonly used to manage mantle-cell lymphoma and multiple myeloma.

Pharmacokinetics Bortezomib is administered as an intravenous bolus injection. More than 80% of the drug is protein-bound and distributed to most body tissues, including the myocardium. The half-life ranges from 9 to 15 hours. Bortezomib is metabolized by the CYP3A4, CYP2C19, and CYP1A2 enzymes in the liver. At present, elimination pathways are not known.

Pharmacodynamics Bortezomib inhibits the activity of the 26S proteasome. This inhibition causes an increase in cell cycle checkpoint activity, a decrease in cell proliferation, and a greater responsiveness to cellular signals for apoptosis. The overall results are inhibition of cancer cell growth and an increase in cancer cell apoptosis.

Side Effects and Adverse Reactions. The most common side effects of bortezomib are nausea, vomiting, anorexia, abdominal pain, bowel changes (constipation or diarrhea), and decreased taste sensation. Most patients also experience either new-onset peripheral neuropathy or worsening of existing peripheral neuropathy, including both loss of sensation and orthostatic hypotension. Other general side effects include headache, insomnia, rash, pruritus, back pain, arthralgia, bone pain, and muscle cramps. Respiratory effects include dyspnea, cough, and pneumonia. Weakness (asthenia) and low-grade fever are relatively common. Moderate to severe thrombocytopenia, anemia, and neutropenia can occur during bortezomib therapy.

Rare but serious cardiopulmonary side effects have been reported. These include new-onset congestive heart failure or worsening of preexisting heart failure, decreased left ventricular function, and pulmonary pneumonitis.

Additional neurologic side effects may include anxiety, fatigue, headaches, lethargy, dizziness, insomnia, and blurred or double vision. An uncommon adverse event is the development of reversible posterior leukoencephalopathy syndrome (RPLS) in patients receiving bortezomib. RPLS is a reversible neurologic condition that can present as seizures, hypertension, headache, lethargy, confusion, visual impairment (including blindness), or other neurologic disturbances.

Because bortezomib causes rapid killing of cancer cells, the development of tumor lysis syndrome (TLS), including hyperkalemia and hyperphosphatemia, is possible. This complication is more likely in patients with a high tumor burden at the start of bortezomib therapy.

Drug Interactions. Drugs that inhibit the CYP3A4 enzyme can lead to increased serum levels of bortezomib, which increases the risk for severe side effects. These drugs include ketoconazole (Nizoral), atazanavir (Reyataz), clarithromycin (Biaxin), indinavir (Crixivan), itraconazole (Sporanox), nefazodone (Serzone, Nefadar), nelfinavir (Viracept), ritonavir (Norvir), saquinavir (Invirase), telithromycin (Ketek), voriconazole (Vfend), amprenavir (Agenerase), aprepitant (Emend), diltiazem (Cardizem), fluconazole (Diflucan), verapamil (Isoptin, Verelan), and cimetidine (Tagamet).

Drugs that induce CYP3A4 enzyme activity may lower bortezomib blood serum levels and reduce its effectiveness. These drugs include rifampin (Rifadin), carbamazepine (Tegretol), and phenytoin (Dilantin).

Angiogenesis Inhibitors

Temsirolimus/Sirolimus

Temsirolimus (Torisel) and its active metabolite, sirolimus, is the major drug in this class. The target of this drug is a protein kinase known as the *mammalian target of rapamycin* (mTOR). When temsirolimus or sirolimus bind to an intracellular protein called FKBP-12, a protein-drug complex forms that directly inhibits the activity of mTOR. Inhibition of mTOR greatly reduces the concentration of vascular endothelial growth factor (VEGF). In addition, by its inhibition of mTOR, a variety of downstream pro–cell-division signal transduction pathways are disrupted, especially in renal cell carcinoma cells. This drug is most commonly used to manage advanced renal cell carcinoma.

Pharmacokinetics Temsirolimus is administered by intravenous infusion. It is extensively metabolized in the liver by CYP3A4 into five active metabolites, including sirolimus. The half-life or temsirolimus is 17 hours, and the half-life of sirolimus is 54 hours. The drug and its metabolites are primarily excreted in the feces.

Pharmacodynamics Temsirolimus and its metabolites bind to an intracellular protein forming a drug-protein complex that inhibits the protein kinase, mTOR, in the tumor cells of renal cell carcinoma (RCC). As a result of this inhibition RCC tumors lose vascularity. Inhibition of mTOR also reduces production of cyclin D so that progression through the cell cycle does not occur. RCC cell proliferation is inhibited, even under hypoxic kidney conditions.

Side Effects and Adverse Reactions. Hypersensitivity reactions to temsirolimus are common, and pretreatment is recommended (see the Nursing Process section). Hyperglycemia is very common (about 89%) in patients receiving temsirolimus, and it may require treatment with oral antidiabetic agents or with insulin. Hematologic side effects of anemia, neutropenia, and thrombocytopenia may be moderate to severe. Other common side effects include headache, insomnia, nausea and vomiting, back pain, arthralgia, myalgia, mucositis, and diarrhea. Integumentary problems such as rash, pruritus, nail disorders, dry skin, acne, and abnormal wound healing may occur.

Respiratory adverse effects of interstitial pneumonitis or other interstitial lung disease are possible. Liver impairment and renal impairment have been reported. Cardiovascular effects of edema formation, chest pain, hypertension, venous thromboembolism, and thrombophlebitis are possible.

Drug Interactions. Drugs that inhibit the CYP3A4 enzyme can lead to increased serum levels of temsirolimus, which increases the risk for severe side effects. These drugs include ketoconazole (Nizoral), atazanavir (Reyataz), clarithromycin (Biaxin), indinavir (Crixivan), itraconazole (Sporanox), nefazodone (Serzone, Nefadar), nelfinavir (Viracept), ritonavir (Norvir), saquinavir (Invirase), telithromycin (Ketek), voriconazole (Vfend), amprenavir (Agenerase), aprepitant (Emend), diltiazem (Cardizem), fluconazole (Diflucan), verapamil (Isoptin, Verelan), and cimetidine (Tagamet).

Drugs that induce CYP3A4 enzyme activity may lower temsirolimus blood serum levels and reduce its effectiveness. These drugs include rifampin (Rifadin), carbamazepine (Tegretol), and phenytoin (Dilantin).

Patients taking antihypertensive drugs such as angiotensin-converting enzyme (ACE) inhibitors or angiotensin II receptor antagonists during temsirolimus therapy are at increased risk for angioedema of the face and upper airways. The combination of temsirolimus and sunitinib may result in dose-limiting integumentary toxicities of erythematous maculopapular rash and gout/cellulitis that require hospitalization. The use of live vaccines such as intranasal influenza, measles, mumps, rubella, oral polio, BCG, yellow fever, varicella, and typhoid vaccines should be avoided during treatment with temsirolimus.

Monoclonal Antibodies

Monoclonal antibodies largely exert their effects on specific cell-membrane surface proteins. All FDA-approved monoclonal antibodies currently used in cancer treatment are given intravenously because their protein structure would be altered and inactivated in the GI tract.

Antigens are normal cell surface proteins or ligands that serve as targets for binding engineered monoclonal antibodies for the treatment of cancer. Ideal target antigens for cancer treatment should be specific to tumor cells; be located on the surface of the tumor cell and not shed into the bloodstream; occur in high numbers; and play a role in tumor cell survival.

Monoclonal antibody therapy is aimed specifically at tumor cells expressing the target antigen. The side effects of monoclonal antibodies are related to activation of the immune system, location of the target antigen, and type of monoclonal antibody. Some monoclonal antibodies sensitize tumor cells to chemotherapy and overcome chemotherapy resistance.

The function of an antibody or immunoglobulin is to recognize an antigen and then interact with other serum proteins to eliminate the antigen or the cell associated with that antigen. The Y shape of the antibody has two active sites (Fab and Fc) and the following two activities:

1. The Fab portion of the antibody contains the antigen-binding sites that recognize and bind to a specific antigen.

2. The Fc or constant region is the end of the antibody that signals the immune system to destroy the cell the antibody has bound.

The binding of antibody to antigen is highly selective, rather like a lock-and-key fit. When an antibody selectively binds to a specific antigen, the antibody/antigen complex acts as a flag or target, drawing other immune cells to the bound cell to destroy it.

A monoclonal antibody recognizes only a single unique antigen and is produced by cloning a single cell. Hybridoma technology, developed in 1975, allowed for mass production of monoclonal antibodies. In this technique, a mouse is inoculated with a purified antigen, and antibody-producing cells are isolated from the mouse spleen. Then antibody producing cells are mixed with myeloma cells (immortal cells that are unable to produce antibodies). When antibody-producing cells fuse with myeloma cells, the resulting cells can make large quantities of the specific monoclonal antibody.

Binding of a monoclonal antibody to its specific target antigen on the cancer cell inactivates or destroys the cancer cell by one or more of the following mechanisms:

- Causing neutralization of tumor cell growth by direct interference with normal biologic activities of the antigen, such as signal transduction of cell growth messages. This cytostatic process can slow growth of the tumor cells.
- Promoting antibody-dependent cell-mediated cytotoxicity (ADCC) in which the Fc portion of the bound monoclonal antibody recruits effector cells such as phagocytes, T-cells, and natural killer cells of the immune system to release cytokines that destroy the target cell.
- Initiating complement-dependent cytotoxicity (CDC), which activates the complement system (a cascade of naturally circulating blood proteins), thus enhancing immune system destruction of antibody-bound cells.
- Directly inducing apoptosis, or programmed cell death.
- In fully human antibodies, the entire antibody has been engineered to contain only human antibody protein sequences. Human antibodies are usually named with the suffix "umab" (see Table 38-2).

Murine monoclonal antibodies are derived from mice. Mouse antibodies have a very short half-life in the human body, are not as effective as human antibodies in eliciting a response from the CDC and ADCC systems, and can cause development of human anti-mouse antibodies (HAMA) that neutralize and render the mouse antibodies ineffective against the tumor. Mouse antibodies are usually named with the suffix "momab." Chimeric monoclonal antibodies end with the suffix "ximab" and contain both human and mouse protein sequences (typically 70% human and 30% mouse).

Humanized monoclonal antibodies ending in "zumab" contain human and gene mouse sequences; however, they are not considered chimeric because they contain more human sequences than do chimeric monoclonal antibodies, usually 90% to 95% human and 5% to 10% mouse.

When monoclonal antibodies are named, not only is the suffix a clue to the makeup, but you can tell what they target by the name. If a generic monoclonal antibody has a *u* in the name, then the target is on a tumor cell. Monoclonal antibodies can be *naked,* or *unconjugated,* with nothing attached to them. They also may be *conjugated* with other anticancer agents (e.g., chemotherapy agents, toxins, or radioisotopes) attached to the antibody. Although agents attached to conjugated antibodies are targeted specifically against tumor cells, nearby healthy cells can still be negatively affected, especially if radioisotopes are used. If the specific target antigen is found on normal cells, these antibodies also cause damage to these cells.

The four major monoclonal antibodies currently in use for cancer therapy are alemtuzumab, ibritumomab tiuxetan, rituximab, and tositumomab (see Table 38-1). Prototype Drug Chart 38-3 lists specific drug information for rituximab.

Alemtuzumab

Alemtuzumab (Campath) is an unconjugated, humanized monoclonal antibody against the cell surface antigen CD52. CD52 is found on most B- and T-lymphocytes; the majority of monocytes, macrophages, and natural killer (NK) cells; and some granulocytes, stem cells, and mature spermatozoa. Although normal cells may express this antigen, malignant cells are much more sensitive to the destructive activity of this antibody. This drug is most commonly used for management of chronic lymphocytic leukemia.

Pharmacokinetics Alemtuzumab is administered as an intravenous infusion. Its average half-life is 12 days, and steady-state levels are reached by about 6 weeks. Because all monoclonal antibodies bind to target cell surfaces and are destroyed along with the target cell, they are cleared as debris from the blood by the liver and eliminated in the feces.

Pharmacodynamics Alemtuzumab binds to leukemic cells expressing the CD52 cell surface antigen and induces antibody-dependent lysis. T-cell prolymphocytic leukemia cells are most sensitive to this drug, but monocytes and monocytic leukemias are resistant to it, despite expressing similar amounts of antigen. As an unconjugated monoclonal antibody, this drug relies on inducing apoptotic signals and the activation of mechanisms such as complement or T-cells to attack and kill the targeted cells. Alemtuzumab is also associated with the release of tumor necrosis factor (TNF), interleukin-6, and interferon gamma.

Side Effects and Adverse Reactions. Alemtuzumab therapy induces fatigue as the most common side effect that is not related to infusion reactions or pancytopenia. This drug carries a boxed warning because of profound bone marrow suppression that may require dose interruptions or reduction, based on severity. This suppression is more profound in patients who are also receiving standard cytotoxic chemotherapy. In addition, infusion reactions with fever, nausea, chills, blood pressure changes, hyperglycemia, and hypoxia are common and often require premedication with antihistamines and acetaminophen. Some patients have reduced reactions with subsequent infusions.

Drug Interactions. Specific drug interactions have not been reported with this drug; however, concomitant administration of drugs with similar pharmacologic effects may cause additive side effects, including toxicity.

PROTOTYPE DRUG CHART 38-3

Rituximab

Drug Class

Monoclonal antibody
Trade Name: Rituxan
Pregnancy Category: C

Dosage

A: IV: 375 mg/m^2 IV once weekly for 4 doses; may be retreated for an additional 4 doses.

Contraindications

Patients who may become pregnant, are pregnant, or are breastfeeding; have previously had hepatitis B; have active bacterial or viral infection; have moderate to severe renal, liver, and/or cardiac disease; or have preexisting pulmonary fibrosis

Drug-Lab-Food Interactions

Drug: Potentiation of hypotension when coadministered with antihypertensive drugs
Potentiation of bone marrow suppression when coadministered with drugs that also cause bone marrow suppression, increasing risk for infection and bleeding
Reduces effectiveness of vaccinations
Lab: None known
Food: None known

Pharmacokinetics

Absorption: 100% bioavailability after intravenous infusion
Distribution: Throughout extracellular fluid, bone marrow, and secondary lymphoid tissues (primarily the spleen)
Metabolism: Degraded by circulating and liver-based phagocytic cells
Excretion: As cellular debris in feces

Pharmacodynamics

Antibody binding specifically to the CD20 cell surface antigen on B-lymphocytes

Therapeutic Effects/Uses

CD20-positive non-Hodgkin's lymphoma (NHL)
Moderate to severe rheumatoid arthritis (lower dosages)
Mode of Action: Binds to CD20-positive B-lymphocytes and lymphoma cells, leading to complement-dependent cytotoxicity, antibody-dependent cellular cytotoxicity, and apoptosis.

Side Effects

Bone marrow suppression with pancytopenia,
Tumor lysis syndrome, hypotension, night sweats, joint and muscle aches, headaches, soreness at injection site

Adverse Reactions

Infusion reactions
Reactivation of dormant viruses, pulmonary fibrosis, cardiac dysrhythmias, heart failure

A, Adult; *IV,* intravenous.

Ibritumomab Tiuxetan

Ibritumomab tiuxetan (Zevalin) is a conjugated murine monoclonal antibody. Ibritumomab is the antibody, and tiuxetan is a linker-chelater to which either Indium-111 or Yttrium-90 can be bound. Like rituximab, this drug combination binds specifically to the human B-lymphocytes that express the CD20 cell surface antigen. This drug is most commonly used for management of B-cell types of non-Hodgkin's lymphoma that express the CD20 cell surface protein.

Pharmacokinetics Ibritumomab tiuxetan is administered as an intravenous infusion. Its physical half-life is 64 hours, and its biologic half-life (determined by radioactivity detection) is 30 hours. The drug is excreted to a slight degree by the kidneys but is mostly eliminated in the feces.

Pharmacodynamics Ibritumomab tiuxetan binds to the CD20 antigen on B-lymphocytes and lymphoma cells. Following binding with the CD20 antigen, beta wave radioactive emissions from the attached radionuclide, Y-90, induce cellular damage by the formation of free radicals in the target and neighboring cells. This cellular damage prevents cells from dividing and also causes cell death.

Side Effects and Adverse Reactions. Ibritumomab tiuxetan carries a boxed warning for infusion reactions with fever, nausea, chills, and blood pressure changes. Severe infusion reactions warrant discontinuing the drug. Less severe infusion reactions may be managed using premedication with antihistamines and acetaminophen. Some patients experience reduced reactions with the second and subsequent infusions. Additional boxed warnings for this drug include severe cytopenia and severe cutaneous and mucocutaneous reactions, fetal damage if given during pregnancy, and possible second malignancies. Just as with all monoclonal antibodies, this drug causes profound bone marrow suppression that may require dose interruptions or reduction (based on severity) and are more profound in patients who are also receiving standard cytotoxic chemotherapy. Ibritumomab tiuxetan side effects and adverse effects not associated with bone marrow suppression or infusion reaction include nausea, vomiting, diarrhea, abdominal pain, cough, rash, pruritus, and urticaria.

Drug Interactions. Ibritumomab tiuxetan increases the risk for bleeding or hemorrhage when used along with anticoagulant or antiplatelet therapy. Other specific drug interactions are not associated with this drug; however, concomitant administration of drugs with similar pharmacologic effects may cause additive side effects, including toxicity.

Tositumomab

Tositumomab (Bexxar) is a murine monoclonal antibody conjugated with the radioactive isotope iodine-131 (^{131}I). Like rituximab and ibritumomab tiuxetan, the antibody portion of this drug binds specifically to the human B-lymphocytes that express the CD20 cell surface antigen. This drug is most commonly used to manage B-cell non-Hodgkin's lymphoma that does not respond to rituximab.

Pharmacokinetics Tositumomab is administered as an intravenous infusion. It has a median blood clearance of 68.2 mg/hour (with 485-mg dosage). The mean total-body effective half-life is 67 hours. The radioisotope (131I) decays over time (half-life is 8 days) and is eliminated in the urine.

Pharmacodynamics Tositumomab induces cytotoxicity by combining the immunologic effects of antibody binding with the preferential targeting of radiation therapy against CD20-positive lymphocytes and lymphoma cells. Actions of the antibody include the induction of complement-mediated cytolysis, antibody-dependent cellular cytotoxicity, and apoptosis. Radiation activity is cytotoxic not only to the cells bound by the radiolabeled antibody, but also to adjacent cells that may not have been bound by the antibody or do not express the target antigen (a process called the *cross-fire effect*). Together, these actions result in sustained depletion of circulating CD20-positive lymphocytes and lymphoma cells.

Side Effects and Adverse Reactions. Tositumomab carries a boxed warning for severe hypersensitivity reactions (anaphylaxis), severe bone marrow suppression, and fetal damage (when used during pregnancy). Specific tositumomab side effects and adverse effects include asthenia, headache, hypotension, nausea, vomiting, abdominal pain, diarrhea, hypothyroidism, cough, dyspnea, pleural effusion, and pneumonia. Toxicities associated with radioimmunotherapy can be acute, delayed, or long-term. The most common acute toxicities are fever, rigors, fatigue, headache, and nausea, whereas hypotension and allergic reactions are less common. Delayed toxicities include shortness of breath, fever, signs of infection, inflammation, pain with urination, rash, sore joints, and bone marrow suppression. Long-term toxicities are myelodysplasia or acute leukemia, secondary malignancies, and hypothyroidism. Just as with other monoclonal antibodies, this drug causes profound bone marrow suppression that may require dose interruptions or reduction, based on severity, and are more profound in patients who are also receiving standard cytotoxic chemotherapy. In addition, infusion reactions with fever, nausea, chills, blood pressure changes, hyperglycemia, and hypoxia are common and often require premedication with antihistamines and acetaminophen. Some patients have reduced reactions with subsequent infusions.

Drug Interactions. Tositumomab increases the risk for bleeding or hemorrhage when used along with anticoagulant or antiplatelet therapy. Other specific drug interactions have not been reported with this drug; however, concomitant administration of drugs with similar pharmacologic effects may cause additive side effects, including toxicity.

Nursing Process
Patient-Centered Collaborative Care

Proteosome Inhibitors, Angiogenesis Inhibitors, and Monoclonal Antibodies for Cancer Treatment

Assessment

- Conduct a detailed medication history, including a list of all concurrent medications, to avoid drug-drug interactions. Include prescriptions, over-the-counter medicines, antacids, dietary supplements, vitamins, and herbal supplements.
- Obtain baseline information about patient's physical condition before initiating targeted therapy and during the treatment period. Include height, weight, vital signs, and laboratory values (CBC, uric acid, electrolytes, hepatic and renal studies, cardiopulmonary assessment, intake and output).
- Assess laboratory studies, including CBC with differential, hepatic and renal studies, electrolytes, and urinalysis, at the beginning of therapy and at specified time intervals during therapy (ranging from weekly to monthly).
- Assess patient/family/caregiver knowledge related to therapeutic regimen.

Nursing Diagnoses

- Deficient knowledge related to targeted therapy regimen
- Risk for impaired skin integrity related to dermatologic effects and toxicity of therapy
- Risk for infection related to bone marrow suppression
- Risk for deficient fluid volume related to GI effects of therapy
- Risk for electrolyte imbalance related to actions of targeted therapy

Planning

- Patient and family will verbalize understanding of targeted therapy as part of anticancer treatment regimen.
- Patient and family will demonstrate understanding of importance of reporting targeted therapy–related side effects and adverse reactions.
- Patient and family will verbalize strategies to minimize risks related to targeted therapy–related side effects.
- Patient's side effects will be managed to a level that the patient can tolerate and are not life threatening.
- Patient will remain infection-free.
- Patient's fluid balance and electrolytes are maintained at expected normal ranges.

Nursing Interventions

- Monitor CBC count with differential and platelet count at baseline, and as often as recommended for specific agents.

- Monitor liver function tests and renal function tests at baseline and at least once monthly during therapy.
- Administer prescribed premedications according to established protocols for specific targeted therapies.
- Follow agency policy for safe handling, preparing, administering, and dispensing of targeted therapy agents.

Bortezomib

- Ensure that patient is adequately hydrated before, during, and after therapy to reduce risk for tumor lysis syndrome.
- Check for manifestations of tumor lysis syndrome (decreased urine output, hyperkalemia, and hypertension).
- Check patient's peripheral sensation and blood pressure at each visit throughout treatment.
- Discuss with health care provider the possible need for prophylactic allopurinol therapy.
- Monitor output and serum potassium levels closely.

Temsirolimus/Sirolimus

- Ensure that resuscitation equipment is nearby, and stay with patient during first 15 minutes of infusion. Thereafter, monitor vital signs every 15 to 30 minutes during infusion and for 1 hour after infusion is complete.
- Check patient's blood glucose level before, during, and after drug administration.
- Ask patient about known hypersensitivity to temsirolimus or sirolimus.
- If prescribed, premedicate patient with diphenhydramine 25 to 50 mg IV, or a similar antihistamine, approximately 30 minutes before the start of each dose.
- Monitor fasting blood glucose and serum electrolytes at baseline and at least every 2 weeks during therapy.
- Monitor chest radiograph at baseline and periodically during therapy for onset of pulmonary toxicity.
- Monitor renal and hepatic function at baseline and then periodically during therapy.

Monoclonal Antibodies

- Infusion reactions are common with intravenous infusion of monoclonal antibodies. Ensure that resuscitation equipment is nearby, and stay with the patient during the first 15 minutes of the infusion. Thereafter, monitor vital signs every 15 to 30 minutes during the infusion and for 1 hour after infusion is complete.
- Ensure that patient is adequately hydrated before, during, and after rituximab therapy to reduce risk for tumor lysis syndrome.
- Monoclonal antibodies against leukocytes can profoundly suppress bone marrow activity and increase patient's risk for infection.
- Monitor for signs and symptoms of infection.
- Patients receiving alemtuzumab are usually prescribed to start antimicrobial prophylaxis beginning on the first day of therapy to reduce the risk for serious infection. Prophylaxis is continued for 2 months after the last dose.
- Gemtuzumab ozogamicin can cause liver toxicity. Closely monitor liver function tests.
- Screen patients for hepatitis B infection before the initiation of rituximab therapy.
- Monitor output and serum potassium levels closely.
- Check for manifestations of tumor lysis syndrome (decreased urine output, hyperkalemia).

General

- Report symptoms of bleeding immediately, including black stools, vomit that looks like coffee grounds, easy bleeding/bruising.
- Report symptoms of adverse effects or severe side effects promptly, especially fever, chills, persistent sore throat, swelling, weight gain, or increasing shortness of breath.
- Report symptoms of liver impairment immediately, including stomach/abdominal pain, yellowing eyes or skin, dark urine, or unusual fatigue.
- Avoid alcohol and nonessential drugs that are cleared by the liver or have liver-toxic effects (e.g., acetaminophen).
- Remind women with childbearing potential to avoid pregnancy throughout treatment and for up to 12 months after treatment is completed.
- Advise breastfeeding patients to stop breastfeeding during and for 60 days after therapy.

Bortezomib

- Advise patient (or family member) to immediately report convulsions, persistent headache, reduced eyesight, increased blood pressure, or blurred vision.
- Teach patient to drink at least 4 liters of fluid daily on day before therapy, on days of therapy, and for 2 days following therapy. Stress importance of keeping fluid intake consistent throughout 24-hour day, and help patients draw up a schedule of fluid intake.
- Advise patient to contact health care provider or cancer clinic immediately if nausea and vomiting prevent adequate fluid intake so they can be started on parenteral fluids.
- Teach patient to avoid driving or operating dangerous machinery during periods of blurred or double vision or when fatigue is extreme.

Temsirolimus/Sirolimus

- Advise patients who develop swelling of the face, lips, or tongue to immediately go to the nearest emergency department.
- Advise nondiabetic patients to report symptoms of hyperglycemia (excessive thirst or any increase in the volume or frequency of urination).
- Advise diabetic patients to test blood glucose levels more frequently. If prescribed dosages of oral antidiabetic

drugs are not sufficient to maintain target blood glucose levels, advise patient to contact the health care provider for diabetic therapy adjustments.

- Advise the patient and live-in family members not to receive any vaccinations without consulting the oncologist.

Monoclonal Antibodies

- Teach patient the signs and symptoms of bone marrow suppression and infection.
- Advise the patient receiving alemtuzumab therapy and live-in family members not to receive any live-virus vaccinations during therapy and for 2 months after therapy is completed.
- Teach patient that monoclonal antibodies conjugated to radioisotopes (ibritumomab tiuxetan and tositumomab) will make him or her somewhat radioactive for a time after the infusion and will pose a radiation hazard to others for 4 to 7 days. Teach patient to use the following precautions for 1 week after each drug administration:
  - Sleep in a separate bed.
  - Maintain a distance of 6 feet or more from children and pregnant women.
  - Limit time spent in public places.
  - Use a separate bathroom and sit while urinating.
  - Wash hands frequently, especially after using the toilet or handling genitals.
  - Drink plenty of liquids (at least 3 L daily).
  - Keep eating utensils separate from others.
  - Wash laundry separately from those of others.
  - Avoid using disposable products.
  - Avoid sexual contact and avoid becoming pregnant.
  - Clean spilled urine, and dispose of body fluid–contaminated material so that others will not inadvertently handle it.

Evaluation

- Patient/family/caregiver education needs are met.
- Patient/family/caregiver understands therapy-related side effects/adverse reactions.
- Patient/family/caregiver understands strategies to minimize side effects/adverse reactions.
- Side effects are managed effectively.
- Patient is free from infection.
- Patient's fluid balance and electrolytes are maintained at expected normal ranges.

CRITICAL THINKING CASE STUDY

MR is a 64-year-old man who is diagnosed with stage III B-cell non-Hodgkin's lymphoma (NHL). He is scheduled to receive rituximab (Rituxan) and a traditional chemotherapy regimen of cyclophosphamide (Cytoxan), doxorubicin (Adriamycin), vincristine (Oncovin), and prednisolone, a combination known as "CHOP." The dosage and schedule of rituximab for this patient is 600 mg IV on days 1 and 6 before the first CHOP chemotherapy cycle (which will be administered on day 8). The next two doses will be administered 2 days before the third and fifth cycles, and the remaining two cycles of rituximab will be administered after the sixth cycle of CHOP on days 134 and 141. MR has a friend who is taking imatinib (Gleevec) daily as an oral drug for chronic myelogenous leukemia. He asks why rituximab must be taken intravenously and, because he has an implanted port, if his spouse, who is an LPN, could administer it at home so he won't have to travel to the cancer center in addition to his standard chemotherapy appointments.

1. What is your best response about why rituximab must be administered intravenously?
2. How are rituximab and imatinib different?
3. Why can't MR's spouse administer rituximab at home?
4. What side effects are specific for rituximab?
5. What are the most common adverse effects of rituximab?
6. What should you teach this patient specifically related to rituximab therapy?

NCLEX STUDY QUESTIONS

1. A patient on chemotherapy for breast cancer asks why she is not receiving trastuzumab (Herceptin) like her sister received with breast cancer. What is the nurse's best response?
   a. "Your breast cancer cells are estrogen receptor–positive, and targeted therapy is not needed."
   b. "You are much older than your sister and would not tolerate the treatment well."
   c. "The drug is expensive, and your insurance does not cover it."
   d. "Your cancer cells do not have the target for trastuzumab."

2. Which instruction is important for the nurse to include when teaching a patient about imatinib (Gleevec) therapy?
    - a. Do not drink grapefruit juice while taking this drug.
    - b. Go immediately to the emergency department if you develop a headache while taking this drug.
    - c. This drug will only work for about 2 months before your cancer develops resistance to it.
    - d. Be sure to take this drug on an empty stomach, either 1 hour before or at least 3 hours after eating.
3. Which is the priority nursing diagnosis for patients receiving epidermal growth factor/receptor inhibitors?
    - a. Risk for infection related to bone marrow suppression and neutropenia
    - b. Risk for impaired skin integrity related to skin side effects
    - c. Risk for injury related to reduced platelet activity
    - d. Disturbed body image related to alopecia
4. The nurse should be most alert to a possible infusion reaction when administering which class of targeted therapies?
    - a. Tyrosine kinase inhibitors
    - b. Multikinase inhibitors
    - c. Monoclonal antibodies
    - d. Proteasome inhibitors
5. A patient taking sunitinib (Sutent) reports that the skin on her hands and feet is red, is painful, and has some blisters. What is the nurse's best action?
    - a. The only action needed is to document the report because this is a mild side effect.
    - b. Advise the patient to wear gloves and mittens when going outdoors in cold weather.
    - c. Advise the patient to avoid getting her hands wet and touching food.
    - d. Notify the oncologist to determine if a dosage reduction is needed.
6. Which action is most important for the nurse to teach a patient taking tositumomab (Bexxar)?
    - a. Avoid drinking alcohol for 1 week after receiving this drug.
    - b. Avoid smoking cigarettes for the entire treatment period.
    - c. Use a separate bathroom and sit while urinating for 1 week after receiving this drug.
    - d. Be sure to take this drug on an empty stomach, either 1 hour before or 2 hours after eating.
7. Which activity will the nurse advise the patient taking erlotinib (Tarceva) to avoid?
    - a. Drinking alcoholic beverages
    - b. Taking aspirin or aspirin-containing drugs
    - c. Exposing self to crowds or persons who are ill
    - d. Exposing self to direct sunlight or tanning beds
8. A patient receiving a targeted therapy asks the nurse why St. John's wort must be avoided. What is the nurse's best response?
    - a. This herbal drug increases blood levels of most targeted therapies and increases the risk for severe side effects or adverse reactions.
    - b. This herbal drug decreases blood levels of most targeted therapies and reduces their effectiveness.
    - c. Targeted therapies increase blood levels of St. John's wort, increasing the risk of an overdose of this herbal agent.
    - d. Targeted therapies bind with St. John's wort in the intestinal tract, preventing absorption of both the drug and the herbal agent.
9. A patient taking imatinib (Gleevec) has gained 5 pounds in the past week. Is this cause for concern?
    - a. No, weight gain is an expected side effect of this drug because it increases the appetite.
    - b. Yes, weight gain is an indication of slow metabolism and possible hypothyroidism.
    - c. Yes, weight gain is an indication of water retention and possible renal impairment.
    - d. Yes, weight gain is an indication of a drug interaction between imatinib and loop diuretics.

OBJECTIVES

- Compare the mechanisms of action of drugs classified as *biologic response modifiers* with those of standard chemotherapy drugs.
- Distinguish among the different types of biologic response modifiers with regard to indications, common side effects and adverse effects, route of administration, and nursing responsibilities.
- Discuss three common side effects of interferons, colony-stimulating factors, and interleukin-2.
- Distinguish anaphylaxis reactions from the anaphylactoid reactions caused by the administration of monoclonal antibody therapy.
- Incorporate the nursing process related to the needs of patients receiving biologic response modifiers.

Biologic response modifiers (**BRMs**) are a class of pharmacologic agents used to enhance the body's immune system. (Another group of immunostimulants are monoclonal antibodies, considered targeted therapy agents, which are discussed in Chapter 38.) **Recombinant DNA** (the genetic engineering process that produces mass quantities of human proteins) and **hybridoma technology** (the process that uses mice to mass-produce monoclonal antibodies) are two advances that have led to commercial mass-production of BRMs (Figure 39-1). Interferons (α, β, γ), colony-stimulating factors, interleukins, and monoclonal antibodies are some currently known BRMs. With the exception of monoclonal antibodies, BRMs are complex proteins produced by the cells of the immune system (Figure 39-2). Individuals taking BRMs are immunocompromised and should be counseled on concurrent drug and herb use (Herbal Alert 39-1).

HERBAL ALERT 39-1

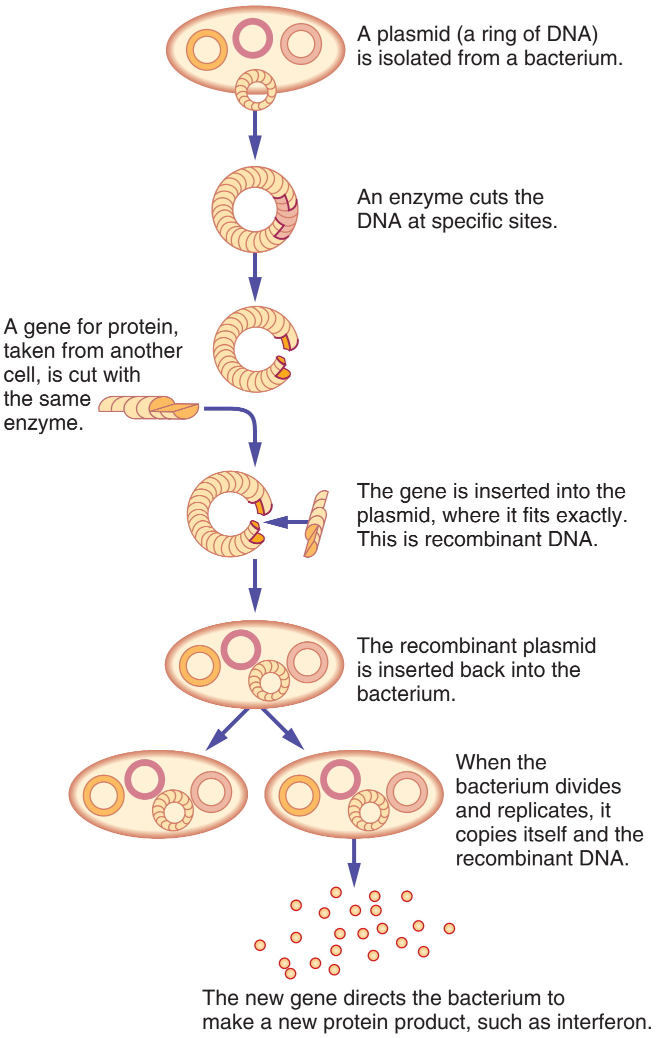
Biologic Response Modifiers

Herbal preparations are generally not recommended for patients receiving BRMs. Several herbs (e.g., elderberry, echinacea, ginseng, goldenseal, green tea) act to stimulate the immune system. However, patients who take BRMs are immunocompromised, and taking any herbal preparations in combination is not recommended.

Three functions of BRM have been identified:

- Enhance host immunologic function (immunomodulation)
- Destroy or interfere with tumor activities (cytotoxic/cytostatic effects)
- Promote differentiation of stem cells (other biologic effects) (see Figure 39-2).

New BMR drugs are always under development and are being investigated for clinical effectiveness. Several categories



A plasmid (a ring of DNA) is isolated from a bacterium.
An enzyme cuts the DNA at specific sites.
A gene for protein, taken from another cell, is cut with the same enzyme.
The gene is inserted into the plasmid, where it fits exactly. This is recombinant DNA.
The recombinant plasmid is inserted back into the bacterium.
When the bacterium divides and replicates, it copies itself and the recombinant DNA.
The new gene directs the bacterium to make a new protein product, such as interferon.

of these drugs have been approved by the U.S. Food and Drug Administration (FDA) and are commercially available: interferons, colony-stimulating factors (erythropoietin-stimulating agents, granulocyte colony-stimulating factors, granulocyte macrophage colony-stimulating factors, thrombopoietic growth factors), and interleukin-2. In addition, a number of monoclonal antibodies have been approved by the FDA (see Chapter 38). Interferons, colony-stimulating factors, and interleukin-2 are discussed in this chapter.

INTERFERONS

Interferons (IFNs) are a family of naturally occurring proteins that were first discovered in the 1950s. Three major types of IFNs have been identified: alpha (α) IFN, beta (β) IFN, and gamma (γ) IFN. Each type is produced by a different cell within the immune system. All three types can be manufactured using recombinant DNA technology. Type I IFNs include IFN-α and IFN-β, which bind selectively to either α- or β-cell surface receptors on effector cells. Interferon gamma (IFN-γ) is a type II IFN and binds to a different cell surface receptor. Common to both Type I and II IFNs are their abilities to (1) regulate the immune system to improve resistance to invading microorganisms and (2) reduce cell proliferation. However, each IFN group has specific functionality as well.

Interferon Alpha

B-cells, T-cells, **macrophages** (type of monocyte—the major phagocytic cells of the immune system), and null cells produce interferon alpha (IFN-α) (Roferon-A, Intron A) in response to the presence of viruses or tumor cells. This interferon has been shown to have antiviral, antiproliferative, and immunomodulatory effects, which means that IFN-α inhibits intracellular replication of viral DNA, interferes with tumor cell growth, and enhances natural killer (NK) cell (antitumor) activity. Recombinant IFN-α is manufactured as Roferon-A (alpha-2a) and Intron A (alpha-2b).

Roferon-A is used in the treatment of (1) hairy cell leukemia; (2) chronic myelogenous leukemia (CML), and (3) AIDS-related Kaposi's sarcoma. Intron A is used in the treatment of (1) malignant melanoma, (2) hairy cell leukemia, (3) follicular non-Hodgkin's lymphoma (NHL), (4) AIDS-related Kaposi sarcoma, and (5) nonmalignant chronic hepatitis B and C and condylomata acuminata. Clinically IFN-α has been used to treat non-Hodgkin's lymphoma (intermediate grade), cutaneous T-cell lymphoma, multiple myeloma, renal cell carcinoma, bladder cancer, and carcinoid (a type of cancer-like disease). Intravesical administration of IFN-α has proved successful for low-grade bladder tumors; intraperitoneal administration of IFN-α has been used to treat ovarian cancer; and intralesional application of IFN-α has been used to treat melanoma and basal cell carcinoma. IFN-α-n3 is a human leukocyte-derived interferon that binds to the same receptors as IFN-α-2b. It is FDA approved for intralesional treatment of refractory or recurring external condylomata acuminata.

Interferon Beta

Interferon beta (IFN-β) (Betaseron, IFN-β-1b) is indicated for the treatment of multiple sclerosis. Specifically this interferon (1) enhances the activity of suppressor T-cells (thymocyte-dependent lymphocytes that turn off an immune reaction—an active part of the cell-mediated immune system), (2) reduces the production of proinflammatory cytokines, (3) reduces antigen-presentation (recruiting members of the immune system to start an immune reaction), and (4) inhibits the movement of lymphocytes in the central nervous system.

Interferon Gamma

Interferon gamma (IFN-γ) (Actimmune, IFN-γ-1b) is indicated for (1) delaying time to disease progression in patients with severe malignant osteopetrosis, (2) reducing the frequency and severity of serious infections related to chronic granulomatous disease, and (3) treating patients with chronic myelogenous leukemia and renal cell carcinoma. IFN-γ-1b has been shown to (1) enhance oxidative metabolism of macrophages, (2) enhance antibody-dependent cell cytotoxicity (ADCC), (3) activate natural killer (NK) cells, and (4) enhance Fc receptors (on antibody) and major histocompatibility antigens (HLA). Malignant osteopetrosis is a congenital disorder hallmarked by two characteristic defects: a defect in osteoclasts that causes bone overgrowth and a defect in phagocyte oxidative metabolism, which can be improved with IFN-γ-1b. Chronic granulomatous disease (CGD) is an inherited error in leukocyte function related to enzyme defects that are responsible for killing invading microorganisms (phagocyte superoxide generation).

Pharmacokinetics IFN-α is metabolized by the liver and filtered by the kidneys. However, the body absorbs approximately 80% of the dose. Peak serum concentrations are reached 4 to 8 hours after administration. IFN-α can be administered subcutaneously (subQ), intramuscularly (IM), and intravenously (IV), although subQ and IM are the preferred routes of administration; subQ administration is recommended for patients with platelet counts below 50,000. Interferons-α-n3, -β and -γ are not discussed further because they are not used as antineoplastic agents.

Side Effects and Adverse Reactions

The major side effect of IFN-α is a flulike syndrome. Other effects occur in the gastrointestinal (GI), neurologic, cardiopulmonary, renal, hepatic, hematologic, and dermatologic systems.

The flulike syndrome is characterized by chills, fever, fatigue, malaise, and myalgias (muscle aches). Chills can occur 3 to 6 hours after IFN-α administration and may progress to rigors. A fever as high as 101° F to 104° F (39° C to 40° C) may occur within 30 to 90 minutes after the onset of chills and last 24 hours. Fatigue, malaise, and myalgias are cumulative side effects; fatigue is the **dose-limiting toxicity** (i.e., the side effect that necessitates a decrease in dose or discontinuation of the drug).

GI side effects include nausea, diarrhea, vomiting, anorexia, taste alterations, and xerostomia (dry mouth). These side effects are mild; anorexia is considered the dose-limiting toxicity for this system.

Neurologic side effects are reversible (after the drug is stopped) and occur in 70% of patients who receive IFN-α. These effects are manifested by mild confusion, somnolence (sleepiness), irritability, poor concentration, seizures, transient aphasia (temporary loss of ability to speak), hallucinations, paranoia, and psychoses. Depression, suicidal ideation, and suicide attempts have occurred in patients taking IFN-α, requiring drug discontinuance.

Cardiopulmonary side effects are dose-related and occur more frequently in older adults and patients with underlying cardiac disease. Side effects include tachycardia, pallor, cyanosis, tachypnea, nonspecific electrocardiographic changes, rare myocardial infarction, and orthostatic hypotension.

Renal and hepatic effects are dose-dependent and usually result in few or no symptoms. The effects are manifested by increased blood urea nitrogen (BUN) and creatinine levels, proteinuria, and elevated transaminases.

Hematologic effects are reversible and dose-limiting. Neutropenia (decreased number of neutrophils in the blood) and **thrombocytopenia** (decreased number of thrombocytes in the blood) are manifestations of such effects. Neutropenia is usually rare and does not predispose the patient to infection. Thrombocytopenia is more common in patients with hematopoietic (affecting the formation of blood cells) diseases than in those with solid tumors.

Maculopapular rashes of the trunk and extremities, pruritus, irritation at the injection site, desquamation (shedding of epithelial cells of the skin), and alopecia are dermatologic effects of IFN-α. Alopecia can occur after more than 4 months of therapy.

Dosing and Preparation

Roferon-A is supplied in prefilled syringes containing 3 million International Units (IU) per 0.5 mL, 6 million IU per 0.5 mL, and 9 million IU per 0.5 mL. All prefilled syringes must be refrigerated at 36° F to 46° F (2° C to 8° C). The syringes should not be frozen or shaken and must be protected from light.

Intron A is supplied as single-use vials (either powder or liquid), multidose vials, and multidose pens. The lyophilized powder is for single-dose use and is available in 10, 18, and 50 million IU. The powder is reconstituted with 1 mL of the provided diluent (sterile water for injection) and gently swirled to dissolve. Final vial concentrations are 10 million IU/mL, 18 million IU/mL, and 50 million IU/mL. The single-dose solution vial for injection is available as 10 million IU (10 million IU/mL). Multidose vials are available as 18 million IU (3 million IU/0.5 mL) and 25 million IU (5 million IU/0.5 mL). Multidose pens for injection are available containing 3 million IU (concentration 22.5 million IU/1.5 mL, delivering 3 million IU/0.2 mL, and containing 6 doses), 5 million IU (concentration 37.5 million IU/1.5 mL, delivering 5 million IU/0.2 mL, and containing 6 doses), and 10 million IU (concentration 75 million IU/1.5 mL, delivering 10 million IU/0.2 mL, and containing 6 doses). Multidose solutions and pens must be stored at 36° F to 46° F (2° C to 8° C). The IFN alphas are listed in Table 39-1 with their dosages, uses, and considerations.

Administration

The administration of IFN-α is contraindicated in patients with a known hypersensitivity to IFN-α, mouse immunoglobulin, or any component of the product. It should be used cautiously in patients with severe cardiac, renal, or hepatic disease and in those with seizure disorders or central nervous system dysfunction. Manufacturers recommend administering the agent to persons 18 years or older only under the supervision of a qualified physician. Women of childbearing age should use contraceptives while receiving IFN-α because of the agent's effects on serum estradiol and progesterone concentrations. Studies have not demonstrated fertility or teratogenic effects in men.

It is recommended that baseline and periodic complete blood counts (CBCs) and liver function tests be performed during the course of IFN therapy. Manufacturers suggest that patients undergo IFN therapy for at least 6 months before a decision is made to continue treatment in those who respond or discontinue treatment in those who do not; optimal treatment duration has not been determined. Patients should be well hydrated during IFN therapy, especially during treatment for malignant melanoma, because this minimizes severe side effects. Dose reductions of 50% or drug discontinuation should be considered if severe adverse reactions occur. Concurrent or prior treatment with chemotherapeutic agents or radiation therapy may increase the effectiveness and toxicity of IFN-α.

COLONY-STIMULATING FACTORS

Hematopoietic **colony-stimulating factors** (CSFs) are proteins that stimulate or regulate the growth, maturation, and differentiation of bone marrow stem cells. CSFs are manufactured through recombinant DNA techniques.

Although CSFs are not directly tumoricidal, they are useful in cancer treatment, because they do the following:

- Decrease the length of posttreatment neutropenia (the length of time **neutrophils,** a type of white blood cell [WBC], are decreased secondary to chemotherapy), thereby reducing the risk, incidence, and duration of infection
- Permit the delivery of higher doses of drugs. **Myelosuppression** (suppression of bone marrow activity) is often a dose-limiting toxicity of chemotherapy. Higher, possibly tumoricidal, doses of drugs cannot be administered because of potentially life-threatening side effects. Colony-stimulating factors can minimize the myelosuppressive toxicity, thus allowing the delivery of higher doses of drugs.
- Reduce bone marrow recovery time after bone marrow transplantation
- Enhance macrophage or granulocyte tumor-, virus-, and fungus-destroying ability

TABLE 39-1 BIOLOGIC RESPONSE MODIFIERS: INTERFERONS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
interferon alpha-2a (Roferon-A)	Hairy-cell leukemia: A: subQ/IM: 3 million IU daily for 16-24 wk, then maintenance dose 3 million IU subQ/IM 3 times/wk Chronic myelogenous leukemia: A: subQ: 9 million IU daily (gradually increase initial dose of 3 million IU daily for 3 days to 6 million IU for 3 days, and then increase to final 9 million IU dose daily	For hairy-cell leukemia, chronic myelogenous leukemia, condyloma acuminata, and AIDS-related Kaposi's sarcoma. Flulike symptoms such as fatigue, aches, pain, fever, chills, and headaches may occur. Pregnancy category: C; PB: UK; t½: 2-3 h
interferon alpha-2b (Intron A)	Hairy cell leukemia: A: Subcutaneous/IM: 2 million IU/m^2 3 times/wk for up to 6 mo Kaposi's sarcoma: A: IM/subQ: Initially: 30 million IU/m^2 3 times/wk until severe intolerance or maximal response at 16 wk; use only 50-million IU strength; 50% dose reduction for severe side effects Malignant melanoma: A: Induction: 20 million IU/m^2 IV over 20 min daily for 5 consecutive d/wk for 4 wk. Maint: 10 million IU/m^2 subQ 3 times/wk for 48 wk Follicular lymphoma: A: 5 million IU subQ 3 times/wk for up to 18 mo, together with anthracycline-containing chemotherapy regimen and then alone after chemotherapy is completed	For hairy-cell leukemia, adjuvant to surgical resection of malignant melanoma, follicular non-Hodgkin's lymphoma, condyloma acuminata, AIDS-related Kaposi's sarcoma, and chronic hepatitis B and non-A hepatitis. Flulike symptoms, fatigue, GI symptoms (nausea, vomiting, diarrhea) may occur. Low blood counts. Monitor CBC, AST, ALT, ALP, LDH. Pregnancy category: C; PB: UK; t½: 2 h
interferon gamma-1b (Actimmune)	Body surface area: >0.5 m^2: A: subQ: 50 mcg/m^2 3 times/wk Body surface area: <0.5 m^2: A/C >1 y: subQ: 1.5 mcg/kg/dose 3 times/wk	For chronic granulomatous disease. Flulike symptoms may occur. Pregnancy category: C; PB: UK; t½: 0.5-6 h
interferon alpha-n3 (Alferon N)	Condylomata acuminata: A: Inject into wart: 250,000 units (0.05 mL) twice weekly; *max:* 8 wk Do not repeat for >3 mo after end of therapy	For recurring condylomata acuminata (genital venereal warts). Flulike symptoms may occur. Monitor CBC, AST, ALT, ALP, LDH. Pregnancy category: C; PB: UK; t½: 6-8 h
interferon beta-1b (Betaseron)	Reduce number of clinical exacerbations of multiple sclerosis: A >18 y: subQ: 0.0625 mg every other day C: Not recommended	For multiple sclerosis (MS). Flulike symptoms may occur. Pregnancy category: C; PB: UK; t½: 8 min–4.3 h

- Prevent severe thrombocytopenia after myelosuppressive chemotherapy

CSFs have been used to treat patients with neutropenia secondary to disease or treatment and can be administered both IV and subQ. The CSFs that are FDA approved for clinical use are erythropoietin-stimulating agents, granulocyte colony-stimulating factor, granulocyte macrophage colony-stimulating factor, and thrombopoietic growth factor.

Erythropoietin-Stimulating Agents

Erythropoietin-stimulating agents (ESAs) include epoetin alpha (Procrit, Epogen) and darbepoetin alpha (Aranesp). **Erythropoietin** is a glycoprotein produced by the kidney; it stimulates red blood cell (RBC) production in response to hypoxia (decreased oxygen to body tissues). Specifically, erythropoietin stimulates the division and differentiation of committed RBC progenitors (parent cells destined to become circulating RBCs) in the bone marrow. ESAs have undergone close scrutiny as data from clinical trials reveal more deaths in cancer patients receiving ESAs when compared to patients receiving RBC transfusions. Therefore ESAs must be used cautiously and only as indicated, because of the increased risk for death and serious cardiovascular events when administered to increase hemoglobin levels to >12 g/dL. Procrit is currently FDA approved for treatment of anemia secondary to chronic renal failure (CRF), zidovudine (AZT)-treated human immunodeficiency virus (HIV) infections, cancer chemotherapy, and anemia in patients who are undergoing surgery. Aranesp is FDA-approved for treatment of anemia resulting from CRF and for use with chemotherapy treatment of nonmyeloid malignancies. The use of ESAs in patients with anemia may decrease the need for and frequency of RBC transfusion.

Pharmacokinetics ESAs can be administered IV (push) or subQ. According to the manufacturer, ESAs administered by IV are eliminated at a rate consistent with first-order kinetics (process by which the drug

PROTOTYPE DRUG CHART 39-1

Epoetin Alpha (Erythropoietin)

Drug Class

Biologic response modifier
Trade Names: Epogen, Procrit, 🍁 Eprex
Pregnancy Category: C
Boxed Warning: ESAs increased the risk for death when given to target Hgb or >12 g/dL in cancer patients.

Dosage

A: Modify dose to keep target hemoglobin <12 g/dL
CRF: 50-100 units/kg 3 times/wk,
Cancer chemotherapy: 50-150 units/kg 3 times/wk or 40,000 units/wk
IV: Dialysis patients (administer at end of dialysis treatment)
IV/subQ: Nondialysis, CRF patients
IV/subQ: 100 U/kg 3 times/wk for 8 wk in AZT-treated HIV-infected patients
Initial dose to those with EPO levels <500 mU/mL and receiving <4200 mg of AZT/wk; patients with EPO level >500 mU/mL unlikely to respond to EPO therapy
subQ: Cancer chemotherapy

Contraindications

Uncontrolled hypertension, hypersensitivity to mammalian cell-derived products or human albumin

Drug-Lab-Food Interactions

Drug: None known
Lab: Increase hematocrit, decrease plasma volume
Iron stores need to be monitored and replaced: Patients with serum ferritin <100 mcg/L, or serum transferring saturation <20% should receive supplemental iron therapy
Food: None known
Caution: Pregnancy, lactation, porphyria; safety in children not established; increased mortality and/or tumor progression, serious cardiovascular and thromboembolic events if target hemoglobin of 12 g/dL exceeded.

Pharmacokinetics

Absorption: subQ, IV
Distribution: PB: UK
Metabolism: $t_{1/2}$: 4-13 h in patients with CRF; 20% less in those with normal renal function
Excretion: In urine

Pharmacodynamics

IV: Onset: 7-10 d
Peak: 2-4 wk
Duration: UK
subQ: Onset: 7-10 d
Peak: 5-4 h
Duration: UK

Therapeutic Effects/Uses

To treat anemia secondary to CRF or AZT (zidovudine) treatment of HIV infections. Use in patients with anemia secondary to cancer chemotherapy
Mode of Action: Increased production of RBCs triggered by hypoxia or anemia

Side Effects

Sense of well-being, hypertension, arthralgias, nausea, edema, fatigue, injection site reaction, rash, diarrhea, shortness of breath

Adverse Reactions

Seizures, hyperkalemia
Life-threatening: Cerebrovascular accident, myocardial infarction

A, Adult; *CRF,* chronic renal failure; *d,* day; *EPO,* erythropoietin; *h,* hour; *HIV,* human immunodeficiency virus; *IV,* intravenous; *PB,* protein-binding; *RBC,* red blood cell; *subQ,* subcutaneous; $t_{1/2}$, half-life; *UK,* unknown; *wk,* week; <, less than; >, greater than; 🍁, Canadian drug name.

is eliminated in part by hepatic and renal blood flow). It has a circulating half-life ranging from approximately 4 to 13 hours in patients with CRF. Plasma levels of Procrit have been detected for at least 24 hours. After subQ administration of Procrit to CRF patients, peak serum levels are achieved within 5 to 24 hours. The half-life of IV-administered Procrit is approximately 20% shorter in normal patients without CRF than in patients with CRF. Prototype Drug Chart 39-1 details the characteristics of this BRM.

Side Effects and Adverse Reactions

It is imperative that the target hemoglobin never exceed 12 g/dL, because the risks of death, serious cardiovascular events, and tumor progression increase at greater values. Close monitoring of hemoglobin response to the ESA and possible dose modification are essential to safe therapy.

The side effects of erythropoietin include hypertension, headache, arthralgias (joint pain), nausea, edema, fatigue, diarrhea, vomiting, chest pain, injection site skin reaction, asthenia (weakness), dizziness, seizures, thrombosis (clots), and allergic reactions. Studies demonstrate that ESA administration is usually well tolerated, and there have been no reports of serious allergic reactions or anaphylaxis. Rare transient skin reactions have been reported. Blood pressure may increase in patients with CRF who receive ESA during the early phase of treatment when the hematocrit (Hct) is on the rise. About 25% of patients with CRF who receive dialysis may require initiation of or increase in antihypertensive therapy. It is postulated that increases in blood pressure may relate to increases in Hct; therefore it is recommended that the dose of ESA be decreased if the Hct increase exceeds 4 points in any 2-week period. Similarly an increase in Hct may cause increased vascular access clotting (clots in the blood vessel at the connection site of the artificial kidney) in hemodialysis patients. Patients may require increased heparinization during ESA therapy to prevent clotting of the artificial kidney. Seizures occurred in patients with CRF who received ESA during clinical trials; activity was particularly evident during the first 90 days of therapy.

Dosing

Procrit should be administered at a starting dose of 50 to 100 units/kg three times a week for patients with CRF. For patients receiving cancer chemotherapy, therapy should not be initiated if the patient's hemoglobin (Hgb) level is ≥10 g/dL. The Hgb should be monitored on a weekly basis until the level becomes stable. The dose should be titrated for each patient to achieve and maintain the lowest Hgb level sufficient to avoid blood transfusions. The initial recommended dose of Procrit in adults is 150 units/kg 3 times a week or 40,000 units per week given subQ. The dose should be reduced by 25% when the Hgb reaches a level needed to avoid a transfusion or increases >1 g/dL in any 2-week period. The dose should be held if the Hgb exceeds a level needed to avoid transfusion and then restarted at 25% below the previous dose. Aranesp dose is 0.45 mcg/kg subQ every week or 500 mcg subQ every 3 weeks. If the rate of Hgb increase is >1 g/dL in 2 weeks or if the Hgb reaches a level needed to avoid transfusion, the dose should be reduced by 25% of the prior dose. If the Hgb exceeds a level needed to avoid transfusion, the dose should be held until the Hgb approaches a level where transfusion may be required. At this point, the dose should be restarted at 25% of the previous dose. ESAs should be discontinued if after 8 weeks of therapy there is no response as measured by Hgb levels or if transfusions are still required. Otherwise, discontinue ESAs at the completion of the course of chemotherapy.

The following situations must be considered and evaluated if a patient does not respond or maintain a response to an ESA:

1. Iron deficiency
2. Underlying infections, inflammatory, or malignant processes
3. Occult blood loss
4. Underlying hematologic disease
5. Folic acid or vitamin B_{12} deficiency
6. Hemolysis
7. Aluminum intoxication
8. Osteitis fibrosa cystica (fibrous degeneration with formation of cysts and nodules secondary to hyperparathyroidism)

Administration

Erythropoietin-stimulating agent administration is contraindicated in patients with (1) uncontrolled hypertension, (2) known hypersensitivity to mammalian cell–derived products, and (3) known hypersensitivity to human albumin or polysorbate. Evaluation of iron stores should occur during erythropoietin therapy. Transferrin saturation should be at least 20%, and ferritin should be at least 100 ng/mL. Iron supplements may be used to increase and maintain transferrin saturation to support erythropoietin-stimulated erythropoiesis. There are no known ESA drug interactions.

Aranesp is available in 1-mL single-dose polysorbate-preserved vials; single-dose prefilled syringes (with polysorbate) in 200-mcg/0.4 mL, 300-mcg/0.6 mL, or 500-mcg/1 mL dose with a 27-gauge ½-inch needle (SingleJect); single-dose prefilled SureClick autoinjectors (with polysorbate) in 25-mcg/0.42 mL, 40-mcg/0.4 mL, 60-mcg/0.3 mL, 100-mcg/0.5 mL, 150-mcg/0.3 mL, 200-mcg/0.4 mL, 300-mcg/0.6 mL, or 500-mcg/1 mL dose.

Preparation of ESAs

1. Do not shake, because shaking may denature the glycoprotein, rendering it biologically inactive.
2. Store the vials at 36° F to 46° F (2° C to 8° C). Do not freeze.
3. The single-dose vial of Procrit contains no preservatives, so any unused drug must be discarded immediately; the multidose vial contains preservatives and must be stored at 36° F to 46° F (2° C to 8° C) between doses; discard 21 days after initial access.
4. Protect Aranesp from light.

Granulocyte Colony-Stimulating Factor

Recombinant DNA technology can produce colony-stimulating factors for human **granulocytes** (a type of WBC responsible for fighting infection). Two commercially available forms are filgrastim (Neupogen) and pegfilgrastim (Neulasta). **Granulocyte colony-stimulating factor** (G-CSF) is a glycoprotein produced by monocytes (a type of WBC), fibroblasts (immature fiber-producing cells), and endothelial cells (cells that line the heart cavity and blood and lymph vessels). It regulates the production of neutrophils (granular leukocytes, WBCs) within the bone marrow. It is approved and available for the following indications to decrease the incidence of infections in patients: (1) receiving myelosuppressive cancer chemotherapy, (2) receiving induction or consolidation chemotherapy for acute myeloid leukemia, (3) receiving bone marrow transplantation for cancer, (4) undergoing peripheral blood progenitor cell collection and therapy (mobilization of stem cells for rescue), and (5) with severe, chronic neutropenia. G-CSF has been evaluated as an adjunct to chemotherapy for both solid tumor and hematologic malignancies and has been evaluated in studies using a number of different chemotherapy regimens. Filgrastim and pegfilgrastim are commercially available forms of G-CSF. Prototype Drug Chart 39-2 gives the drug data for filgrastim (Neupogen) and pegfilgrastim (Neulasta).

Filgrastim

Pharmacokinetics Filgrastim administration results in a two-phase neutrophil response. An early response is seen within 24 hours of

PROTOTYPE DRUG CHART 39-2

Filgrastim and Pegfilgrastim

Drug Class

Granulocyte colony-stimulating factor
Trade Names: Neupogen, G-CFS, Neulasta
Pregnancy Category: C

Dosage

A: IV inf/subQ: 5 mcg/kg/d Neupogen
C: Neupogen: 5 mcg/kg/d; Neulasta: 6 mg subQ × 1 during chemotherapy cycle
Refer to specific protocols.

Contraindications

Hypersensitivity to *Escherichia coli*–derived proteins; 24 hours before or after cytotoxic chemotherapy
Caution: Pregnancy, lactation; safety in children not established

Drug-Lab-Food Interactions

Drug: None known
Lab: Increase lactic acid, LDH, alkaline phosphatase; transient increase in WBC and neutrophil count
Food: None known

Pharmacokinetics

Absorption: subQ: Well absorbed
Distribution: PB: UK
Metabolism: t½: 2-3.5 h; Neulasta: 15-80 h
Excretion: Probably in urine

Pharmacodynamics

IV/subQ: Onset: 24 h
Peak: 3-5 d
Duration: 4-7 d

Therapeutic Effects/Uses

To decrease incidence of infection in patients receiving myelosuppressive chemotherapeutic agents, including patients with AML undergoing induction or consolidation therapy, and patients undergoing bone marrow transplant; adjunct to chemotherapy for both solid tumor and hematologic malignancies; and for mobilization of progenitor stem cells used in autologous transplant; also for treatment of patients with severe, chronic neutropenia.
Mode of Action: Increases production of neutrophils, and enhances their phagocytosis

Side Effects

Nausea, vomiting, skeletal pain, alopecia, diarrhea, fever, skin rash, anorexia, headache, cough, chest pain, sore throat, constipation

Adverse Reactions

Neutropenia, dyspnea, splenomegaly, psoriasis, hematuria
Life-threatening: Thrombocytopenia, myocardial infarction, adult respiratory distress syndrome in patients with sepsis, splenic rupture

A, Adult; *C,* child; *d,* day; *h,* hour; *inf,* infusion; *IV,* intravenous; *LDH,* lactate dehydrogenase; *PB,* protein-binding; *subQ,* subcutaneous; *t½,* half-life; *UK,* unknown.

administration, and then there is a second peak in circulating neutrophils following the chemotherapy-induced **nadir** (lowest value of formed blood cells). The proliferation-induced increase in neutrophils usually begins 4 to 5 days after administration is initiated, but timing may vary based on type and dose of myelosuppressive therapy, the patient's underlying disease, and prior treatment history. The elimination half-life of G-CSF in both normal patients and those with cancer is 3.5 hours. Clearance rates are approximately 0.5 to 0.7 mL/min/kg.

Side Effects and Adverse Reactions. The side effects of filgrastim therapy include nausea, vomiting, skeletal pain, alopecia, diarrhea, neutropenia, fever, mucositis, fatigue, anorexia, dyspnea, headache, cough, skin rash, chest pain, generalized weakness, sore throat, stomatitis, constipation, and pain of unspecified origin. Of these reactions, bone pain is the only consistently observed reaction attributed to G-CSF therapy, and this relates to the expanding bone marrow. Bone pain is of mild to moderate severity and is well controlled with nonopioid analgesia. It occurs more frequently in patients receiving higher IV doses (20 to 100 mcg/kg/day) than in patients receiving lower subcutaneous doses (3 to 10 mcg/kg/day). Rarely splenic rupture may occur, and patients who complain of left upper abdominal pain and/or shoulder tip pain should be evaluated for an enlarged spleen or splenic rupture. The drug may rarely cause adult respiratory distress syndrome in neutropenic patients who are septic and may cause sickle cell crisis in patients with sickle cell disease.

Dosing. G-CSF should not be administered during the 24-hour period before and the 24-hour period after chemotherapy agents are administered because of the potential sensitivity of rapidly dividing myeloid cells to chemotherapy. It may stimulate the proliferation of rapidly dividing cells that may be destroyed by chemotherapy drugs. G-CSF can be administered subQ and by IV infusion. The recommended starting dose of G-CSF for patients receiving myelosuppressive cancer chemotherapy is 5 mcg/kg/day subQ or IV infusion over 15 to 30 minutes. Doses may be increased in 5-mcg/kg/day increments for each chemotherapy cycle, according to the duration and severity of the absolute neutrophil count nadir. The **absolute neutrophil count (ANC)** is determined using the following equation:

$$\text{Total white blood cell count (WBC)} \times (\%\ \text{neutrophils} + \%\ \text{bands})$$

G-CSF causes a transient increase in neutrophil counts 1 to 2 days after initiation of therapy. However, to achieve a sustained therapeutic response, G-CSF therapy should continue until postchemotherapy nadir ANC is $10{,}000/\text{mm}^3$. Premature discontinuation of G-CSF therapy before expected ANC recovery is not recommended.

The dose of G-CSF given for bone marrow transplantation is 10 mcg/kg/day IV infusion over 4 hours or as a continuous IV infusion over 24 hours. The first dose must be given at least 24 hours after cytotoxic chemotherapy and at least 24 hours after bone marrow infusion. Subsequent dosing is determined by the ANC. The dose of G-CSF for stem cell mobilization (progenitor cell collection) is 10 mcg/kg/day subQ or IV as a bolus or continuous infusion. It is given for at least 4 days prior to the first leukapheresis procedure and is continued until the last leukapheresis. Monitor the ANC closely, and modify the dose if the WBC is >100,000/mm^3.

Administration. G-CSF administration has no demonstrable effects on fertility in male and female rats. Its carcinogenic potential is not known. Caution should be used when G-CSF is given to pregnant and nursing patients. The manufacturer recommends that the benefits justify the potential risks.

Filgrastim's efficacy has not been demonstrated in children, although safety data indicate that it does not cause any greater toxicity in children than in adults.

There has been no evidence of other drug interaction with filgrastim, but its administration is contraindicated in patients with known hypersensitivity to *Escherichia coli*–derived proteins.

Preparation. Neupogen is supplied either as 1-mL vials containing 300 mcg of filgrastim; 1.6-mL vials containing 480 mcg of filgrastim; or prefilled syringes (SingleJect with UltraSafe needle guard) containing 300 mcg of filgrastim in 0.5 mL (600 mcg/mL), or 480 mcg in 0.8 mL (600 mcg/mL). Both the vials and prefilled syringes are preservative-free, therefore the manufacturer recommends that the vials and syringes be used one time only and that any vials left at room temperature for longer than 6 hours be discarded. Filgrastim should be stored in a refrigerator at 36° F to 46° F (2° C to 8° C). Do not freeze or shake the vials or syringes.

Pegfilgrastim

Pharmacokinetics Filgrastim is eliminated via the kidneys. Pegfilgrastim is a pegylated form of filgrastim (**pegylation** is the process of adding a polyethylene glycol [PEG] molecule to another molecule). Pegfilgrastim therefore becomes a larger substance and as a result is not as easily eliminated from the body via the kidneys. The decreased rate of urinary excretion keeps this G-CSF in the body longer, thereby reducing the frequency of injections. Filgrastim requires daily IV or subQ injections for up to 2 weeks to be effective, whereas pegfilgrastim only requires a once per chemotherapy cycle injection to be effective. For patients and their families, this reduction in dosing frequency alleviates the burden of daily clinic trips for injections.

Pegfilgrastim is FDA approved to decrease the incidence of infections and febrile neutropenia in patients with nonmyeloid malignancies receiving chemotherapy associated with clinically significant febrile neutropenia.

Side Effects and Adverse Reactions. Side effects are similar to those of filgrastim with the most frequently reported adverse event being bone pain. This bone pain is effectively reduced with acetaminophen 650 mg or ibuprofen 400 mg by mouth every 4 to 6 hours.

Dosing and Administration. The recommended dose is 6 mg of pegfilgrastim administered as a single subcutaneous injection given at least 24 hours after chemotherapy once per chemotherapy cycle. The drug should not be administered during the period 14 days before and 24 hours after administration of cytotoxic chemotherapy.

Preparation, Storage, and Handling. Pegfilgrastim is supplied in prefilled syringes containing 6 mg in 0.6 mL. This colorless, preservative-free medication should be protected from light and refrigerated at 36° F to 46° F (2° C to 8° C). Only one injection is to be given, and any unused pegfilgrastim must be discarded.

Granulocyte-Macrophage Colony-Stimulating Factor

Granulocyte-macrophage colony-stimulating factor (GM-CSF), or sargramostim, belongs to a group of growth factors that support survival, clonal expression, and differentiation (maturation) of hematopoietic progenitor cells. It induces partially committed progenitor (parent) cells to divide and differentiate in the granulocyte macrophage (a type of WBC responsible for recognizing and destroying bacteria through phagocytosis) pathway. GM-CSF, unlike G-CSF, is a multilineage factor that promotes proliferation of myelomonocytic, megakaryocytic, and erythroid progenitors. Activated T-cells, endothelial cells, and fibroblasts produce GM-CSF in vivo. Commercial production of GM-CSF is accomplished through recombinant DNA technology and is FDA approved for use to induce and support myeloid reconstitution (1) after induction of chemotherapy in acute myelogenous leukemia (AML), (2) in both autologous and allogeneic bone marrow transplant (BMT), (3) for mobilization of autologous peripheral blood progenitor cells, and (4) in BMT failure or delayed engraftment. Sargramostim (GM-CSF) is commercially available as Leukine. Prototype Drug Chart 39-3 presents the drug data for sargramostim.

Pharmacokinetics GM-CSF has been found to effectively accelerate myeloid engraftment (growth and development of bone marrow and subsequent circulating blood cell activity) in autologous BMT. After autologous BMT in patients with non-Hodgkin's lymphoma, acute lymphoblastic leukemia, or Hodgkin's disease, GM-CSF administration resulted in accelerated myeloid engraftment, decreased duration of antibiotic use, reduced duration of infectious episodes, and shortened hospitalizations.

Side Effects and Adverse Reactions

Side effects of GM-CSF administration include fever, mucous membrane disorder, asthenia (weakness), malaise, sepsis, nausea, diarrhea, vomiting, anorexia, liver damage, alopecia, rash, peripheral edema, dyspnea, blood dyscrasias, renal dysfunction, and central nervous system disorder. This drug should be administered with caution to patients with preexisting pleural or pericardial effusions, because it may increase fluid retention. Sequestration of granulocytes in the pulmonary circulation has been seen with GM-CSF administration. The phenomenon results in dyspnea and suggests that special attention be given to respiratory symptoms during or immediately following GM-CSF infusions, a caution that is especially important for patients with underlying pulmonary

PROTOTYPE DRUG CHART 39-3

Sargramostim

Drug Class Granulocyte-macrophage colony-stimulating factor Trade Name: Leukine Pregnancy Category: C	**Dosage** A: IV: 250 mcg/m^2/d as a 2-h infusion for 21 d after autologous BMT Some protocols use subQ administration.
Contraindications Within 24 h of chemotherapy administration or within 12 h after last dose of radiation therapy; excessive leukemia myeloid blast cells in bone marrow; hypersensitivity to GM-CSF, yeast-derived products Caution: Pregnancy, lactation, heart failure; safety in children not established; not FDA approved for children	**Drug-Lab-Food Interactions** Drug: Lithium and steroids may increase effect Lab: Increase in WBC and platelet counts, bilirubin, creatinine, and liver enzymes Food: None known
Pharmacokinetics Absorption: IV: Essentially complete Distribution: PB: UK Metabolism: t½: 2 h Excretion: Probably in urine	**Pharmacodynamics** IV: Onset: 7-14 d Peak: UK Duration: Baseline WBCs by 1 wk after administration
Therapeutic Effects/Uses To accelerate growth and development of bone marrow and circulating blood cell activity in autologous BMT Mode of Action: Increased production and functional activity of eosinophils, macrophages, monocytes, and neutrophils	
Side Effects Generally well tolerated; diarrhea, fatigue, chills, weakness, local irritation at injection site; peripheral edema, rash	**Adverse Reactions** Pleural/pericardial effusion, rigors, GI hemorrhage, dyspnea

A, Adult; *BMT,* bone marrow transplant; *d,* day; *FDA,* Food and Drug Administration; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *PB,* protein-binding; *subQ,* subcutaneous; *t ½,* half-life; *UK,* unknown; *WBC,* white blood cell; *wk,* week.

disease. The GM-CSF infusion should be reduced by half or discontinued if the patient experiences dyspnea.

Supraventricular dysrhythmia has been observed during GM-CSF infusion, suggesting cautious administration in patients with preexisting cardiac disease. Renal and hepatic dysfunction, as indicated by elevated serum creatinine, bilirubin, and liver function tests, have occurred with GM-CSF administration. If these values become elevated, GM-CSF dosage should be reduced or therapy interrupted.

GM-CSF therapy is contraindicated in patients with excessive leukemia myeloid blast cells in the bone marrow or peripheral blood (>10%) and in patients with a known hypersensitivity to GM-CSF, yeast-derived products, or any component of the product. Because of the sensitivity of rapidly dividing hematopoietic progenitor cells to cytotoxic chemotherapy or radiologic therapy, GM-CSF should not be administered within 24 hours before or after chemotherapy or within 12 hours before or after radiation therapy.

GM-CSF should be administered to pregnant or nursing patients only if clearly indicated (i.e., if benefits outweigh risks). Efficacy in the pediatric population has not been established.

Carcinogenic, mutagenic, or fertility effects have not been determined. A full evaluation of drug interactions has not been conducted, but drugs that may potentiate the myeloproliferative effects of GM-CSF, such as lithium and corticosteroids, should be used with caution.

Dosing

The recommended dose of GM-CSF is 250 mcg/m^2/day for 21 days as a 2-hour infusion beginning 2 to 4 hours after autologous bone marrow infusion; or on day 11 (4 days after completion of induction chemotherapy for AML) until ANC is >1500 cells/mm^3 for 3 consecutive days. When used for stem cell mobilization, the dose is given daily prior to and throughout the period of stem cell collection; when used after stem cell reinfusion, the drug is administered daily until ANC is >1500 cells/mm^3. When used for bone marrow transplant graft failure or delay, the drug is given daily for 14 days as a 2-hour infusion, followed by an assessment of the response.

Administration

GM-CSF is administered IV over 2 to 4 hours or subQ. The drug should not be administered within 24 hours of chemotherapy administration or within 12 hours before or after radiation therapy. Manufacturers recommend dose reduction or discontinuation in the presence of a severe adverse reaction, appearance of blast cells (immature, possibly malignant cells), or disease progression. To avoid potential complications associated with leukocytosis, therapy should be stopped if the ANC is >20,000 cells/mm^3.

Preparation

Leukine is available as lyophilized Leukine (250 mcg), a sterile, white, preservative-free powder that requires reconstitution, or as liquid Leukine (500 mcg). The powder is reconstituted with 1 mL of sterile water for injection. During reconstitution, the diluent should be directed at the side of the vial and the contents gently swirled but not shaken. Further dilution with 0.9% sodium chloride only is done in preparation for the 2-hour IV infusion. The final concentration of solution should be >10 mcg/mL. The infusion should be completed within 6 hours of preparation to ensure stability and potency. Sargramostim powder, reconstituted vials, and diluted solution should be refrigerated at 36° F to 46° F (2° C to 8° C). The liquid sargramostim vials can be stored at 36° F to 46° F (2° C to 8° C) for up to 20 days once the vial has been entered.

Thrombopoietic Growth Factor

Oprelvekin is recombinant human interleukin-11, a platelet (thrombocyte) growth factor available commercially as Neumega. This product can potentially prevent recurrent severe chemotherapy-induced thrombocytopenia. According to the manufacturer, Oprelvekin stimulates megakaryocyte and thrombocyte production. This effect results in functionally and morphologically normal circulating platelets. Neumega is indicated to prevent severe thrombocytopenia and to reduce the need for platelet transfusions following myelosuppressive chemotherapy in adult patients with nonmyeloid malignancies who are at high risk for severe thrombocytopenia. Neumega is not indicated following myeloablative (transplant) chemotherapy. It has the potential to prevent severe thrombocytopenia and to reduce the need for platelet transfusions following myelosuppressive chemotherapy. Efficacy is most evident in those who experience severe thrombocytopenia following the previous chemotherapy cycle. However, in clinical practice the potential side effect of severe fluid retention limits its use.

Pharmacokinetics Product dosing should begin 6 to 24 hours after completion of chemotherapy. Studies have shown that daily subQ dosing for 14 days increased the platelet count in a dose-dependent way. Platelet counts begin to increase between 5 and 9 days after the start of Neumega administration. After administration of the product stops, the platelet count continues to increase for up to 7 days, returning to baseline within 14 days.

Animal studies demonstrate that Neumega is cleared rapidly from the serum and distributed to highly perfused organs. The kidney is the primary route of elimination, although most of the product is metabolized before excretion. Neumega is contraindicated in patients with a history of hypersensitivity to the product or any of its components and should be used cautiously in patients with heart failure.

Side Effects and Adverse Reactions

The side effects of Neumega include serious fluid retention, cardiovascular events, ophthalmologic events, and severe hypersensitivity reactions. Fluid retention as evidenced by peripheral edema; exertional dyspnea; and worsening of preexisting pleural effusions, ascites, and pericardial effusions is reversible within several days once the product is discontinued. Transient atrial arrhythmias (fibrillation or flutter) have occurred in approximately 10% of patients, and postmarketing reports have indicated that ventricular arrhythmias occur as well. These arrhythmias may be related to fluid retention, advanced age, or underlying cardiac disease. Papilledema and transient visual blurring have been reported in about 1.5% of patients. Postmarketing reports also indicate that hypersensitivity reactions including anaphylaxis have occurred, and the drug should be discontinued if there is evidence of symptomatic bronchospasm or anaphylaxis.

Drug interactions include Neumega and diuretics, which may increase the risk of hypokalemia. Laboratory abnormalities include a decrease in hemoglobin related to increased plasma volume (fluid retention), decreased serum proteins (albumin, transferrin, gamma globulins), and elevated plasma fibrinogen. No studies have been done to assess the carcinogenic potential of the product, and no studies have determined its safety and effectiveness in children, pregnant patients, or breastfeeding patients. Use in these situations should be evaluated carefully.

Dosing

The recommended dose of Neumega in adults is 50 mcg/kg given once daily. It should be administered subQ as a single injection in the thigh, abdomen, hip, or upper arm. If the patient has severe renal impairment (creatinine clearance <30 mL/min), the dose is reduced to 25 mcg/kg. Safety and efficacy in pediatric patients has not been established. The first dose of Neumega should be given 6 to 24 hours after completion of chemotherapy. Platelet counts should be monitored to determine the duration of Neumega therapy.

Administration

Administration should continue until the postnadir count is >50,000 cells/mcL. Dosing beyond 21 days is not recommended. Neumega should be discontinued at least 2 days before chemotherapy is begun.

Preparation

Neumega is available for subQ administration in single-use vials containing 5 mg of oprelvekin as a sterile, lyophilized powder. When reconstituted with 1 mL of sterile water for injection, it has a concentration of 5 mg/mL. Reconstituted Neumega is a clear, colorless, isotonic solution with a pH of 7.0. During reconstitution, avoid excessive shaking of the vial; direct sterile water for injection at the side of the vial, and swirl contents gently. Do not reenter or reuse a single-dose vial. The parenteral drug product should be visually inspected and discarded if there is discoloration or visible particulate matter.

Neumega should be used within 3 hours of reconstitution whether it has been stored refrigerated at 36° F to 46° F (2° C to 8° C) or at room temperature up to 77° F (25° C). Do not freeze, and do not shake the reconstituted product.

Patient Information

Self-administration of Neumega should not be attempted until the patient fully understands the health care provider's instructions about its preparation, correct dose, and proper method for injection. The injection site should not be rubbed. The dose is given at the same time each day. If a dose is missed, the next scheduled dose should be taken. Note: Patients can safely receive concurrent doses of ESA, G-CSF, and Neumega. Different injection sites should be used for each agent.

INTERLEUKIN-2

Interleukins are a group of proteins produced by the body's WBCs—the lymphocytes. Because interleukins are hormone-like glycoproteins manufactured by the lymphocytes, they are sometimes called **lymphokines**. One of the most widely studied interleukins is interleukin-2 (IL-2).

First defined in 1976, this substance was found to have antitumor activities, particularly in renal cell carcinoma and malignant melanoma. IL-2 is produced commercially through recombinant DNA technology as aldesleukin (Proleukin). Proleukin is FDA approved for treatment of metastatic renal cell carcinoma and metastatic melanoma.

Pharmacokinetics Proleukin, administered either by IV infusion or subQ injection, is rapidly distributed to the extravascular extracellular space and eliminated by the kidneys. The serum half-life of IL-2 is short, and because of this rapid clearance, IL-2 is administered frequently in short infusions.

Side Effects and Adverse Reactions

Proleukin should be administered only to patients with normal cardiac and pulmonary function, because side effects may be severe. The principal serious side effects are capillary leak syndrome and infection. *Capillary leak syndrome* is characterized by loss of vascular tone with leakage of plasma fluids into the extravascular space, including the lungs. This can cause hypotension and decreased blood circulation to vital organs, resulting in angina, myocardial infarction, respiratory distress, gastrointestinal bleeding, and mental status changes. Infection may result from alteration in neutrophil function, with the most severe infection being sepsis and bacterial endocarditis. Many patients with cancer are at risk for gram-negative infections related to their indwelling central lines, and they may benefit from prophylactic antibiotic therapy. The most frequent side effects reported as a result of IL-2 use include hypotension, nausea, vomiting, diarrhea, mental status changes, oliguria/anuria, anemia, thrombocytopenia, fever, chills, sinus tachycardia, pulmonary congestion, dyspnea, pain at injection site, fatigue, weakness, malaise, and elevated liver function tests. Table 39-2 lists adverse events/effects of IL-2. According to the manufacturer, Proleukin should be discontinued permanently if certain organ system toxicities occur (Table 39-3) and should be held and restarted under specific parameters for other toxicities (Table 39-4).

Preparation

Proleukin is supplied in single-use vials, each containing 22 million (1.3 mg) units of Proleukin. Unreconstituted vials should be stored refrigerated at 36° F to 46° F (2° C to 8° C). After aseptic reconstitution with 1.2 mL of sterile water for injection (*not* bacteriostatic water), each mL contains 18 million IU (1.1 mg) of Proleukin. Inject the sterile water into the vial, and swirl gently; do not shake. The resulting solution should be a clear, colorless to pale yellow liquid. Withdraw the indicated dose of Proleukin from the vial, and dilute in a 50-mL 5% dextrose IV bag. If not used immediately, the IV bag can be stored for 48 hours in a refrigerator. Infuse over a 15-minute period through nonfiltered IV tubing. Discard any unused portion of the reconstituted drug. Table 39-5 presents route, dosage, use, and considerations information for Proleukin.

TABLE 39-2 INCIDENCE OF ADVERSE EVENTS TO INTERLEUKIN-2

EVENTS BY BODY SYSTEM	% OF PATIENTS	EVENTS BY BODY SYSTEM	% OF PATIENTS
Cardiovascular		**Gastrointestinal**	
Hypotension	85	Nausea and vomiting	87
(requiring pressors)	71	Diarrhea	76
Sinus tachycardia	70	Stomatitis	32

KERATINOCYTE GROWTH FACTOR

Keratinocyte growth factor (palifermin) is available commercially as Kepivance and is indicated for decreasing the incidence and duration of severe oral mucositis in patients with hematologic malignancies receiving myelotoxic therapy requiring hematologic stem cell support. There is no evidence at this time as to its safety (may stimulate growth of tumors dependent upon this growth factor) or efficacy in patients receiving chemotherapy for solid tumors. The drug is contraindicated in patients with hypersensitivity to *E. coli*–derived therapy or to palifermin.

Pharmacokinetics Kepivance binds to the keratinocyte growth factor receptor on epithelial cells, such as those of the oral mucosa, and initiates proliferation, differentiation, and migration of the epithelial cells. Thicker buccal mucosa is laid down, and in clinical trials this led to a significantly reduced incidence of grade 3/4 oral mucositis, a decreased duration of oral mucositis, and less opioid use for oral mucositis in transplant patients.

TABLE 39-4 INTERLEUKIN-2 DOSE HELD AND GIVEN

ORGAN SYSTEM	HOLD DOSE IF:	SUBSEQUENT DOSES MAY BE GIVEN IF:
Cardiovascular	Patient has atrial fibrillation, supraventricular tachycardia, or bradycardia that requires treatment or is recurrent or persistent	Patient is asymptomatic with full recovery to normal sinus rhythm
	Systolic BP is <90 mm Hg with increasing requirements for pressors	Systolic BP is 90 mm Hg and stable or improving requirements for pressors
	Any ECG change consistent with MI or ischemia with or without chest pain; suspicion of cardiac ischemia	Patient is asymptomatic, MI has been ruled out, clinical suspicion of angina is low
Pulmonary	O_2 saturation <94% on room air or <90% with 2 L O_2 by nasal prongs	O_2 saturation 94% on room air or 90% with 2 L O_2 by nasal prongs
Central nervous system	Mental status changes, including moderate confusion or agitation	Mental status changes have completely resolved
Systemic	Patient has sepsis syndrome and is clinically unstable	Sepsis syndrome has resolved, patient is clinically stable, and infection is under treatment
Renal	Serum creatinine is >4.5 mg/dL, or serum creatinine is ≥4 mg/dL in presence of severe volume overload, acidosis, or hyperkalemia	Serum creatinine is <4 mg/dL, and fluid and electrolyte status is stable
	Persistent oliguria, urine output of 10 mL/h for 16-24 h with rising serum creatinine	Urine output is >10 mL/h with decrease of serum creatinine 1.5 mg/dL or normalization of serum creatinine
Hepatic	Signs of hepatic failure, including encephalopathy, increasing ascites, liver pain, and hypoglycemia	All signs of hepatic failure have resolved[*]
Gastrointestinal	Stool guaiac is repeatedly >3 to 4+	Stool guaiac is negative
Skin	Bullous dermatitis or marked worsening of preexisting skin condition (avoid topical steroid therapy)	All signs of bullous dermatitis have been resolved

[*] Discontinue all further treatment for that course. Consider starting a new course of treatment at least 7 weeks after cessation of adverse event and hospital discharge.

BP, Blood pressure; *ECG*, electrocardiographic; *h*, hour; *MI*, myocardial infarction; O_2, oxygen; >, greater than; <, less than.

TABLE 39-5 INTERLEUKIN[*]

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
interleukin-2 (Proleukin)	Two 5-day treatment periods separated by a rest period A: IV: 600,000 IU/kg (0.037 mg/kg) by 15-min IV infusion q8h for maximum of 14 doses. Following 9 days of rest, repeat the schedule for another 14 doses, for a maximum of 28 doses per course	For treating metastatic renal cancer and metastatic melanoma. *Do not* give dexamethasone during treatment unless absolutely necessary; it may negate the effects of Proleukin.

[*] Patients receiving IL-2 by any route, in any dose, and in any setting—inpatient or outpatient—should be monitored closely for signs of toxicity.

A, Adult; *d*, day; *h*, hour; *IV*, intravenous; *min*, minute; *wk*, week.

Side Effects and Adverse Reactions

The most common side effects of Kepivance are skin toxicities (rash, erythema, edema, pruritus) and oral toxicities (tongue thickening, oral/perioral dysesthesia [distorted sensation], tongue discoloration, and taste alteration). Other side effects are hypertension and transient increases in serum lipase and serum amylase. The most concerning potential adverse reaction is the possible stimulation of tumor growth, in that some solid tumors are composed of epithelial cells, which are stimulated to grow when Kepivance stimulates keratinocyte growth receptors. For this reason, the drug is approved only in hematologic malignancies treated with myelotoxic chemotherapy requiring stem cell support.

Drug Interactions

Kepivance binds to heparin, so lines containing heparin should be flushed with normal saline prior to the infusion of Kepivance and following the infusion of Kepivance.

Dosing and Administration

Kepivance must not be administered within 24 hours of, during, or within 24 hours after the administration of myelotoxic chemotherapy. Kepivance is administered in a dose of 60 mcg/kg/day as an IV bolus for 3 consecutive days *before* and 3 consecutive days *after* myelotoxic chemotherapy, for a total of 6 doses. The third dose must be administered 24 to 48 hours before chemotherapy. The fourth dose is given on the same day as, but after, stem cell reinfusion and at least 4 days after the third dose of Kepivance. Flush central lines with normal saline before and after the administration of Kepivance if heparin has been used in the line.

Preparation, Storage, and Handling

Kepivance is available as a white lyophilized powder for IV injection, which is reconstituted with 1.2 mL Sterile Water for Injection, USP, yielding a clear, colorless solution with a Kepivance concentration of 5 mg/mL. Do not shake or vigorously agitate the vial to mix. The reconstituted solution remains stable refrigerated in its carton at 36° F to 46° F (2° C to 8° C) for up to 24 hours. Prior to administration, remove the reconstituted vial from the refrigerator and bring it to room temperature for up to 1 hour, while keeping it protected from light in its carton. Discard the vial if it is out of the refrigerator for more than 1 hour. Also discard any remaining drug after the dose is withdrawn. Do not freeze or filter the drug.

SAFETY: Preventing Medication Errors

Do not confuse…

- sargramostim (Leukine) with Leukeran
- interferon alpha-2a (Roferon-A) with interferon alpha-2b
- interferon alpha-2b (Intron-A) with interferon alpha-2a
- interferon beta-1a (Avonex, Rebif) with interferon beta-1b (Avelox)
- interferon beta-1b (Betaseron) with interferon beta-1a
- interleukin-2 (IL2, Proleukin) with interferon 2

Nursing Process

Patient-Centered Collaborative Care

Biologic Response Modifiers

Assessment

- Obtain a drug and herbal supplement history from patient.
- Obtain baseline information about patient's physical status. This should include height, weight, vital signs, laboratory values (complete blood count [CBC], uric acid, electrolytes, blood urea nitrogen [BUN], creatinine, and liver function tests), cardiopulmonary assessment, intake and output, skin assessment, daily activities status (i.e., ability to perform activities of daily living [ADLs], sleep-rest cycle), nutritional status, presence or absence of underlying symptoms of disease, and use of current or past medication and treatment.
- Assess CBC (with filgrastim, pegfilgrastim, sargramostim, and oprelvekin) before therapy and biweekly throughout therapy to avoid leukocytosis and thrombocytosis. Assess renal and hepatic function tests in patients with dysfunction (liver enzymes, BUN, serum creatinine). With erythropoietin-stimulating agents, assess hematocrit and hemoglobin, serum ferritin, and serum iron–transferrin saturation. Most patients will need supplemental iron. Desired levels are >100 ng/mL for serum ferritin and >20% for serum iron–transferrin saturation. Assess blood pressure before start of and, especially, early in therapy.
- Obtain baseline data regarding patient's psychosocial status, including educational level, ability and desire to learn, support systems, past coping strategies, presence or absence of emotional difficulties, and self-care abilities.
- Assess patient for signs and symptoms associated with BRMs, such as fatigue, chills, diarrhea, and weakness. With filgrastim, be alert to changes in patients with preexisting cardiac conditions. With oprelvekin, assess for peripheral edema and impact on cardiopulmonary system. With aldesleukin, assess for signs and symptoms of capillary leak syndrome, including hypotension and respiratory distress.
- Assess patient's/family's/caregiver's ability to administer subcutaneous BRMs.
- Determine patient's/family's/caregiver's understanding of BRMs and related side effects.

Nursing Diagnoses

- Imbalanced nutrition, less than body requirements, related to side effects of biologic response modifier therapy
- Risk for infection related to side effects of cancer chemotherapy treatments and disease condition
- Risk for deficient fluid volume related to side effects of cancer therapy

- Impaired oral mucous membrane skin integrity related to side effects of cancer chemotherapy and disease condition
- Fatigue related to side effects of biologic response modifier therapy
- Anxiety related to cancer diagnosis and unknown outcomes of treatment
- Fear related to cancer diagnosis
- Risk for caregiver role strain related to cancer diagnosis, treatment, and care responsibilities

Planning

- Patient and family will verbalize understanding of importance of reporting BRM-related side effects.
- Patient and family will demonstrate correct and safe BRM administration.
- Patient and family will identify strategies to deal with BRM-related side effects.
- Patient will remain free from infection.
- Patient will remain free from hemorrhage.

Nursing Interventions

- Monitor patient's temperature at onset of chills.
- Encourage patient to drink at least 2 L of fluid a day to promote excretion of cellular breakdown products. Assess need for IV hydration, especially during IFN-α therapy.
- Encourage patient to rest when tired and to notify health care provider if profound fatigue or anorexia occurs.
- Administer antiemetic as necessary. Premedicate patient with antiemetic, and administer it around the clock for 24 hours after BRM administration to further delay nausea or vomiting.
- Premedicate patient with acetaminophen to reduce chills and fever and with diphenhydramine to reduce nausea.
- Administer BRM at bedtime to decrease consequences of fatigue.
- Cover patient with blankets to promote warmth during chills.
- Administer prescribed meperidine 25 mg to 50 mg intravenously to decrease rigors.
- Consult dietitian, social worker, and physical or occupational therapist as necessary.
- Provide patient and family the opportunity to discuss effect of BRM therapy on quality of life.
- Refer patient and family to financial counselor if reimbursement of BRM therapy is problematic.
- Continue with same brand of BRM, and notify health care provider if considering changing brand.
- Remember that palifermin binds with heparin, so if patient has a central line, it must be flushed with normal saline before and after administration of palifermin.

Patient Teaching

General

- Explain to patient and family the rationale for BRM therapy.
- Explain the frequency and rationale for studies and procedures during BRM therapy.
- Inform patient and family that most BRM side effects disappear within 72 to 96 hours after discontinuation of therapy.
- Instruct patients of childbearing age to use contraceptives during BRM therapy and for 2 years after completion of therapy.
- Provide patient with information regarding the effect of BRM-related fatigue on ADLs, including sexuality.
- Explain to patient that concurrent use of herbal products with BRM therapy is not recommended (see Herbal Alert 39-1).

Side Effects

- Advise patient to report episodes of difficulty in concentration, confusion, or somnolence.
- Report weight loss.
- Report dyspnea, palpitations, and signs of infection or bleeding.

Self-Administration

- Demonstrate correct drug administration techniques.
- Provide patient/family/caregiver with written or video instructions regarding BRM self-administration.

Cultural Considerations

- Obtain an interpreter when necessary; do not rely on family members who may not fully disclose personal information because of cultural norms.

Evaluation

- Evaluate patient/family/caregiver education strategies by asking them to discuss the potential effect of BRM therapy on quality of life.
- Evaluate patient/family/caregiver BRM administration technique if appropriate.
- Periodically evaluate patient/family/caregiver management of BRM-related side effects.
- Patient will have a decreased incidence of infection after autologous bone marrow transplantation.
- Patient will have a decreased incidence of thrombocytopenia after chemotherapy administration.

KEY WEBSITES

Biological Response Modifier: What Is It?: *arthritis.about.com/cs/enbrel/a/biologics.htm*

National Cancer Institute: *www.cancer.gov/cancertopics/treatment/biologicaltherapy*

CRITICAL THINKING CASE STUDY

JW, a 55-year-old man, has metastatic non–small-cell cancer of the lung. His past treatment regimen included external-beam chest irradiation and combination chemotherapy. Two weeks before hospitalization, JW received a course of carboplatin and paclitaxel as an outpatient. He was admitted to the hospital with neutropenia, thrombocytopenia, and anemia. Upon assessment, he was cachectic, weak, and able to perform activities of daily living only with assistance. Admitting laboratory data were Hgb (hemoglobin) 6.9, Hct (hematocrit) 20.6, platelets 16,000, and WBC 600 with ANC 96. JW was started on filgrastim 480 mcg/day subQ; erythropoietin 40,000 units subQ once a week; and oprelvekin 50 mcg/kg/day subQ. Parenteral antibiotic therapy was also initiated. Nursing diagnoses for JW included a potential for infection related to neutropenia, bleeding related to thrombocytopenia, fatigue related to anemia, and anxiety related to hospitalization. Nursing interventions included the following:

- Maintaining scrupulous hand washing and hand hygiene before and after patient contact
- Allowing no one with cold or infection to enter patient's room
- Obtaining vital signs and pulmonary assessment every 4 hours
- Inspecting all sites associated with risk for infection (e.g., venipuncture sites, oral cavity, perirectal area) during every shift
- Protecting skin and mucosal surfaces to prevent entry of microorganisms by not using suppositories, enemas, or urinary catheters; by avoiding IM injections; and by not obtaining rectal temperatures
- Monitoring laboratory values daily
- Providing bedside range-of-motion exercises and physical therapy
- Giving emotional support to patient/family/caregiver
- Instructing patient/family/caregiver about giving subQ injections and self-assessment of the signs and symptoms of infection and bleeding

JW continued therapy with filgrastim, oprelvekin, and erythropoietin. The following laboratory data were obtained:

TESTS	DAY 1	DAY 2	DAY 3	DAY 4	DAY 5
Hgb	6.9	6.5	7.1	7.8	7.9
Hct	20.6	19.4	21.6	22.9	22.9
Platelets	16,000	15,000	16,000	20,000	30,000
WBC/ ANC	600/96	1000/0	1200/168	9400/4700	31,500/18,270

Filgrastim was discontinued on day 5, and antibiotics were discontinued on day 4, but erythropoietin and oprelvekin were continued. JW's physical therapy was continued in the physical therapy department. JW refused red blood cell transfusion on the basis of religious beliefs and was discharged to home (day 5) on procrit 40,000 units subQ once a week and Neumega 50 mcg/kg/day subQ for 7 days.

1. Why were filgrastim, oprelvekin, and erythropoietin indicated?
2. What is an often overlooked side effect of erythropoietin?
3. Based on this side effect, what should be closely monitored in a patient receiving this agent?
4. Why was the patient receiving this agent on days 1 to 4, and what risk does this pose?

NCLEX STUDY QUESTIONS

1. A patient is being seen regularly for treatment of chronic leukemia. The nurse understands that this patient has been treated with interferon alpha (Roferon-A). What is the primary action of this biologic response modifier?
   a. Enhancing immune function, producing white blood cells, producing antigen/antibody reaction
   b. Causing allergic reactions, producing red blood cells, producing interferon
   c. Immunomodulation, causing cytotoxic/cytostatic effects, differentiating stem cells
   d. Producing cytokines, producing interleukin, fighting infection
2. A patient diagnosed with malignant melanoma, a skin cancer, is treated with interferon alpha-2a (Roferon-A). The nurse teaches this patient about which side effect of interferon-α that will make the patient uncomfortable?
   a. Increase in white blood cells
   b. Increase in red blood cells
   c. Flulike syndrome
   d. Gastrointestinal symptoms
3. A patient has a low platelet count (thrombocytopenia). The nurse reviews the list of medications and is aware that platelet production can be stimulated with which drug?
   a. epoetin alpha (Procrit, Epogen)
   b. filgrastim (Neupogen)
   c. interleukin-11 (Oprelvekin)
   d. sargramostim (Leukine)
4. The nurse is caring for a patient who has previously received the biologic response modifiers as a subcutaneous injection either in the outpatient office or at home. The patient will now be receiving a drug that is not often used in clinical practice because of its serious side effects and must be administered by IV infusion. Which drug meets this criterion?
   a. Epoetin alpha (Procrit or Epogen)
   b. interleukin-2 (Proleukin)
   c. G-CSF (Neupogen or Neulasta)
   d. GM-CSF (sargramostim)

5. A patient lives 120 miles from her oncologist's medical office and relies on her working son for transportation to and from the office. In developing a plan of care for the patient, the nurse understands that the order for pegfilgrastim was prescribed for what reason?
   - a. Pegfilgrastim is eliminated via the kidneys.
   - b. Pegfilgrastim is a pegylated filgrastim.
   - c. Pegfilgrastim is not easily eliminated from the body.
   - d. Pegfilgrastim requires a once per chemotherapy cycle injection.
6. The nurse is caring for a patient who arrives at the outpatient office for a scheduled dose of an erythropoietin-stimulating agent (ESA) to be administered today. The patient arrives with the following laboratory values noted on the chart: Hemoglobin 12.8 mg/dL; platelet count 148,000/mm^2; white blood cell count 4.800/mm^2. Which action is most appropriate for the nurse to implement?
   - a. Discuss with the health care provider the potential need for a colony-stimulating factor such as G-CSF based on the laboratory results.
   - b. Contact the health care provider to discuss the laboratory results and a possible discontinuation of the ordered ESA.
   - c. After comparing the patient's laboratory results with the previous results, discuss the laboratory values with the health care provider to determine whether a colony-stimulating factor such as interleukin-2 should be given.
   - d. Discuss with the health care provider the potential need for more laboratory tests prior to administration of ESA.

Answers: 1, a; 2, c; 3, c; 4, b; 5, d; 6, c.

UNIT XIII

Respiratory Agents

The respiratory tract is divided into two major parts: (1) the upper respiratory tract, which consists of the nares, nasal cavity, pharynx, and larynx, and (2) the lower respiratory tract, which consists of the trachea, bronchi, bronchioles, alveoli, and alveolar-capillary membrane. Air enters through the upper respiratory tract and travels to the lower respiratory tract, where gas exchanges occur. Figure XIII-1 illustrates these components.

Ventilation and *respiration* are distinct terms and should not be used interchangeably. Ventilation is the movement of air from the atmosphere through the upper and lower airways to the alveoli. *Respiration* is the process whereby gas exchange occurs at the alveolar-capillary membrane. Respiration has three phases: ventilation, perfusion, and diffusion.

1. *Ventilation* is the phase in which oxygen passes through the airways. With every inspiration, air is moved into the lungs, and with every expiration, air is transported out of the lungs.
2. *Perfusion* involves blood flow at the alveolar-capillary bed. Perfusion is influenced by alveolar pressure. For gas exchange to occur, the perfusion of each alveolus must be matched by adequate ventilation. Factors such as mucosal edema, secretions, and bronchospasm increase resistance to air flow and decrease ventilation and diffusion of gases.

Larynx
Lower respiratory tract
Trachea
Bronchus
Bronchioles
Diaphragm
Alveoli
Capillary
Red blood cell
Alveolar capillary membrane

FIGURE XIII–1 Basic structures of the respiratory tract.

3. *Diffusion* (molecules move from higher to lower concentration) of gases takes place when oxygen passes into the capillary bed to be circulated, and carbon dioxide leaves the capillary bed and diffuses into the alveoli for ventilatory excretion.

The chest cavity is a closed compartment bounded by 12 ribs, the diaphragm, thoracic vertebrae, sternum, neck muscles, and intercostal muscles between the ribs. The pleura are membranes that encase the lungs. The lungs are divided into lobes; the right lung has three lobes, and the left lung has two lobes. The heart, which is not attached to the lungs, lies on the mid-left side in the chest cavity.

LUNG COMPLIANCE

Lung compliance is the lung volume based on the unit of pressure in the alveoli. This volume determines the lung's ability to stretch. Factors that influence lung compliance include (1) connective tissue (collagen and elastin) and (2) surface tension in the alveoli, which is controlled by surfactant. Surfactant lowers the surface tension in the alveoli and prevents interstitial fluid from entering. Increased lung compliance is present with chronic obstructive pulmonary disease (COPD), and decreased lung compliance occurs with restrictive pulmonary disease. With low compliance, there is decreased lung volume resulting from increased connective tissue or increased surface tension. The lungs become "stiff," and it takes greater-than-normal pressure to expand lung tissue.

CONTROL OF RESPIRATION

Oxygen (O_2), carbon dioxide (CO_2), and hydrogen (H^+) ion concentration in the blood influence respiration. *Chemoreceptors* are sensors that are stimulated by changes in these gases and ions. The central chemoreceptors, located in the medulla near the respiratory center and cerebrospinal fluid, respond to an increase in carbon dioxide and a decrease in pH by increasing ventilation. However, if the carbon dioxide level remains elevated, the stimulus to increase ventilation is lost.

Peripheral chemoreceptors, located in the carotid and aortic bodies, respond to changes in oxygen (PO_2) levels. A low blood oxygen level (PO_2 <60 mm Hg) stimulates the peripheral chemoreceptors, which in turn stimulate the respiratory center in the medulla, and ventilation is increased. If oxygen therapy increases the oxygen level in the blood, the PO_2 may be too high to stimulate the peripheral chemoreceptors, and ventilation will be depressed.

BRONCHIAL SMOOTH MUSCLE

The tracheobronchial tube is composed of smooth muscle whose fibers spiral around the tracheobronchial tube, becoming more closely spaced as they near the terminal bronchioles (Figure XIII-2). Contraction of these muscles constricts the airway. The sympathetic and parasympathetic nervous systems affect the bronchial smooth muscle in opposite ways. The vagus nerve (parasympathetic nervous system) releases acetylcholine, which causes bronchoconstriction. The sympathetic nervous system releases epinephrine, which stimulates the $beta_2$ receptor in the bronchial smooth muscle, resulting in bronchodilation. These two nervous systems counterbalance each other to maintain homeostasis.

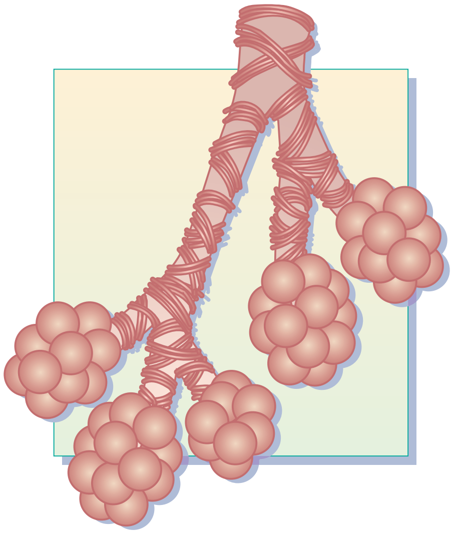

FIGURE XIII–2 Bronchial smooth muscle fibers become more closely spaced as they near the alveoli.

Cyclic adenosine monophosphate (cyclic AMP) in the cytoplasm of bronchial cells increases bronchodilation by relaxing the bronchial smooth muscles. The pulmonary enzyme phosphodiesterase can inactivate cyclic AMP. Drugs of the methylxanthine group (theophylline) inactivate phosphodiesterase, thus permitting cyclic AMP to function.

This unit includes Chapter 40, Drugs for Upper Respiratory Disorders, and Chapter 41, Drugs for Lower Respiratory Disorders. Chapter 40 discusses drugs used to relieve cold symptoms, such as antihistamines, decongestants, antitussives, and expectorants. Drugs used to alleviate and control airway obstruction are presented in Chapter 41. These include the sympathomimetics (adrenergics), particularly the $beta_2$ adrenergics; methylxanthines such as theophylline; leukotriene receptor antagonists; glucocorticoids; cromolyn sodium; and mucolytics.

OBJECTIVES

- Compare antihistamine, decongestant, antitussive, and expectorant drug groups.
- Differentiate between rhinitis, sinusitis, and pharyngitis.
- Describe the side effects of nasal decongestants and how they can be avoided.
- Apply the nursing process for drugs used to treat the common cold.

KEY TERMS

acute pharyngitis, p. 581
acute rhinitis, p. 573
allergic rhinitis, p. 574
antihistamines, p. 574
antitussives, p. 578
common cold, p. 573
decongestants, p. 574
expectorants, p. 578
rebound nasal congestion, p. 575
rhinorrhea, p. 574
sinusitis, p. 581

Upper respiratory infections (URIs) include the common cold, acute rhinitis, sinusitis, and acute pharyngitis. The **common cold** is the most prevalent type of URI. Adults have an average of 2 to 4 colds per year, and children have an average of 4 to 12 colds per year. Incidence is seasonally variable, with approximately 50% of the population experiencing a winter cold and 25% experiencing a summer cold. A cold is not considered a life-threatening illness, but, it causes physical and mental discomfort and loss of time at work and school. The common cold is an expensive illness in the United States—more than $40 billion is spent each year on over-the-counter (OTC) cold and cough preparations.

COMMON COLD, ACUTE RHINITIS, AND ALLERGIC RHINITIS

The common cold is caused by the rhinovirus and affects primarily the nasopharyngeal tract. **Acute rhinitis** (acute inflammation of the mucous membranes of the nose) usually accompanies the common cold. Acute rhinitis is not the same as **allergic rhinitis,** often called *hay fever,* which is caused by pollen or a foreign substance (e.g., animal dander). Nasal secretions increase in both acute rhinitis and allergic rhinitis.

A cold is most contagious 1 to 4 days before the onset of symptoms (the incubation period) and during the first 3 days of the cold. Transmission occurs more frequently from touching contaminated surfaces and then touching the nose or mouth than it does from viral droplets released by sneezing.

The groups of drugs used to manage cold symptoms include antihistamines (H_1 blockers), decongestants (sympathomimetic amines), antitussives, and expectorants. These drugs can be used singly or in combination preparations.

Symptoms of the common cold include **rhinorrhea** (watery nasal discharge), nasal congestion, cough, and increased mucosal secretions. If a bacterial infection secondary to the cold occurs, infectious rhinitis may result, and nasal discharge becomes tenacious, mucoid, and yellow or yellow-green. The nasal secretions are discolored by white blood cells and cellular debris that are by-products of the fight against the bacterial infection. Antibiotics used to treat bacterial respiratory infections are discussed in Chapters 29, 30, and 31.

Antihistamines

Antihistamines, H_1 blockers or H_1 antagonists, compete with histamine for receptor sites, preventing a histamine response. The two types of histamine receptors, H_1 and H_2, cause different responses. When the H_1 receptor is stimulated, the extravascular smooth muscles, including those lining the nasal cavity, are constricted. With stimulation of the H_2 receptor, an increase in gastric secretions occurs, which is a cause of peptic ulcer (see Chapter 48). These two types of histamine receptors should not be confused. Antihistamines decrease nasopharyngeal secretions by blocking the H_1 receptor.

Although antihistamines are commonly used as cold remedies, these agents can also treat allergic rhinitis. However, the antihistamines are not useful in an emergency situation such as anaphylaxis. Most antihistamines are rapidly absorbed in 15 minutes, but they are not potent enough to combat anaphylaxis.

First-Generation Antihistamines

The antihistamine group can be divided into first and second generations. Most first-generation antihistamines cause drowsiness, dry mouth, and other anticholinergic symptoms, whereas second-generation antihistamines have fewer anticholinergic effects and a lower incidence of drowsiness. Many OTC cold remedies contain a first-generation antihistamine, which can cause drowsiness; therefore patients should be alerted not to drive or operate dangerous machinery when taking such medications. The anticholinergic properties of most antihistamines cause dryness of the mouth and decreased secretions, making them useful in treating rhinitis caused by the common cold. Antihistamines also decrease the nasal itching and tickling that cause sneezing.

The first-generation antihistamine diphenhydramine (Benadryl) has been available for years and is frequently combined with other ingredients in cold remedy preparations. Its primary use is to treat rhinitis. Prototype Drug Chart 40-1 lists the pharmacologic behavior of diphenhydramine.

Pharmacokinetics Diphenhydramine can be administered orally, intramuscularly (IM), or intravenously (IV). It is well absorbed from the gastrointestinal (GI) tract, but systemic absorption from topical use is minimal. It is highly protein-bound (98%) and has an average half-life of 2 to 7 hours. Diphenhydramine is metabolized by the liver and excreted as metabolites in the urine.

Pharmacodynamics Diphenhydramine blocks the effects of histamine by competing for and occupying H_1 receptor sites. It has anticholinergic effects and should not be used by patients with narrow-angle glaucoma. Drowsiness is a major side effect of the drug; in fact, it is sometimes used in sleep-aid products. Diphenhydramine is also used as an antitussive (i.e., it alleviates cough). Its onset of action can occur in as few as 15 minutes when taken orally and IM. IV administration results in an immediate onset of action. The duration of action is 4 to 6 hours.

Diphenhydramine can cause CNS depression if taken with alcohol, narcotics, hypnotics, or barbiturates.

SAFETY: Preventing Medication Errors

Do not confuse:

- **Benadryl** (antihistamine) with **benazepril** (ACE inhibitor)

Side Effects of Most First-Generation Antihistamines. The most common side effects of first-generation antihistamines are drowsiness, dizziness, fatigue, and disturbed coordination. Skin rashes and anticholinergic symptoms (e.g., dry mouth, urine retention, blurred vision, wheezing) may also occur.

Second-Generation Antihistamines

The second-generation antihistamines are frequently called *nonsedating antihistamines* because they have little to no effect on sedation. In addition, these antihistamines cause fewer anticholinergic symptoms. Although a moderate amount of alcohol and other central nervous system (CNS) depressants may be taken with second-generation antihistamines, many clinicians advise against such use.

The second-generation antihistamines cetirizine (Zyrtec), fexofenadine (Allegra), and loratadine (Claritin) have half-lives between 7 and 15 hours. Azelastine (Astelin) is a second-generation antihistamine that has a half-life of 22 hours and is administered by nasal spray. Table 40-1 lists the first- and second-generation antihistamines used to treat allergic rhinitis.

Nasal and Systemic Decongestants

Nasal congestion results from dilation of nasal blood vessels caused by infection, inflammation, or allergy. With this dilation, there is a transudation of fluid into the tissue spaces, resulting in swelling of the nasal cavity. Nasal **decongestants** (sympathomimetic amines) stimulate the alpha-adrenergic receptors, producing vascular constriction (vasoconstriction) of the capillaries within the nasal mucosa. The result is

PROTOTYPE DRUG CHART 40-1

Diphenhydramine

Drug Class
Antihistamine
Trade Names: Benadryl, 🍁 Aller-Dryl
Pregnancy Category: B

Dosage
A: PO: 25-50 mg q6-8h; *max:* 300 mg/d
C: 6-12 y: PO: 12.5-25 mg q4-6h
C: 2-6 y: PO: 6.25 q4-6h
A: IM/IV: 10-50 mg as single dose, q4-6h; *max:* 400 mg/d
C: IM/IV: 5 mg/kg/d in 4 divided doses; *max:* 300 mg/d

Contraindications
Acute asthmatic attack, severe liver disease, lower respiratory disease, neonate
Caution: Narrow-angle glaucoma, benign prostatic hypertrophy, pregnancy, newborn or premature infant, breastfeeding, urinary retention

Drug-Lab-Food Interactions
Drug: Increase CNS depression with alcohol, opioids, hypnotics, barbiturates; avoid use with MAOIs

Pharmacokinetics
Absorption: PO: Well absorbed
Distribution: PB: 98%
Metabolism: $t\frac{1}{2}$: 2-7 h
Excretion: In urine as metabolites

Pharmacodynamics
PO: Onset: 15-45 min
Peak: 1-4 h
Duration: 4-6 h
IM: Onset: 15-30 min
Peak: 1-4 h
Duration: 4-7 h
IV: Onset: Immediate
Peak: 0.5-1 h
Duration: 4-7 h

Therapeutic Effects/Uses
To treat allergic rhinitis and itching; to prevent motion sickness; sleep aid; antitussive
Mode of Action: Blocks histamine$_1$, thereby decreasing allergic response; affects respiratory system, blood vessels, and GI system

Side Effects
Drowsiness, dizziness, fatigue, nausea, vomiting, urinary retention, constipation, blurred vision, dry mouth and throat, reduced secretions, hypotension, abdominal pain, diarrhea, hearing disturbances; excitation in children; photosensitivity

Adverse Reactions
Life-threatening: Agranulocytosis, hemolytic anemia, thrombocytopenia

A, Adult; *C,* child; *CNS,* central nervous system; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; $t\frac{1}{2}$, half-life; 🍁, Canadian drug name.

shrinking of the nasal mucous membranes and a reduction in fluid secretion (runny nose).

Nasal decongestants are administered by nasal spray or drops or in tablet, capsule, or liquid form. Frequent use of decongestants, especially nasal spray or drops, can result in tolerance and **rebound nasal congestion** (rebound vasodilation instead of vasoconstriction). Rebound nasal congestion is caused by irritation of the nasal mucosa.

Nursing Process
Patient-Centered Collaborative Care

Antihistamine: Diphenhydramine

Assessment

- Determine baseline vital signs.
- Obtain drug history; report if drug-drug interaction is probable.
- Assess for signs and symptoms of urinary dysfunction, including retention, dysuria, and frequency.
- Note complete blood count (CBC) during drug therapy.
- Assess cardiac and respiratory status.
- Obtain history of environmental exposures if patient has an allergic reaction regarding drugs, recent foods eaten, and stress.

Nursing Diagnoses

- Ineffective airway clearance related to nasal congestion
- Risk for imbalanced fluid volume related to excessive sweating and loss of fluids
- Sleep deprivation related to frequent coughing

Planning

- Patient will have decreased nasal congestion, mucosal secretions, and cough.
- Patient will sleep 6 to 8 hours per night.

TABLE 40-1 ANTIHISTAMINES FOR TREATMENT OF ALLERGIC RHINITIS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
First-Generation Antihistamines		
Alkylamine Derivatives		
brompheniramine maleate (Dimetane)	A: PO: 4-8 mg q6-8h or SR: 12-24 mg once daily; *max:* 24 mg/d A: subQ/IM/IV: 5-20 mg q6-12h; *max:* 40 mg/d C: >6 y: PO: 2-4 mg q6-8h; *max:* 12 mg/d	For allergies. Also present in various cough and decongestant formulas. Pregnancy category: C; PB: UK; t½: 12-34 h
chlorpheniramine maleate (Chlor-Trimeton)	A: PO: 2-4 mg q4-6h; *max:* 24 mg/24 h SR: 12-18 mg b.i.d.; *max:* 36 mg/d C: 6-12 y: PO: 2 mg q4-6h; *max:* 12 mg/d	For allergies including allergic rhinitis. May be used in combination with nasal decongestant. Pregnancy category: C; PB: 72%; t½: 10-24 h
dexchlorpheniramine maleate	A/C >12 y: PO: 2 mg (5 mL) q4-6h C: >6 y: PO: 1 mg (2.5 mL) q4-6h C: 2-5 y: PO: 0.5 mg (1.25 mL) q4-6h	For allergic rhinitis. May be used with epinephrine to treat anaphylactic reaction. Pregnancy category: B; PB: 72%; t½: 20-24 h
Ethanolamine Derivatives		
clemastine fumarate	A/C: >12 y: PO: 1.34-2.68 mg b.i.d./t.i.d.; *max:* 8 mg/d	For allergic rhinitis and urticaria. Pregnancy category: B; PB: UK; t½: 4-6 h
diphenhydramine (Benadryl)	See Prototype Drug Chart 40-1.	
Piperidine Derivatives		
cyproheptadine HCl	A: PO: 4-20 mg/d in divided doses; *max:* 0.5 mg/kg/d C: 7-14 y: PO: 4 mg/d in divided doses; *max:* 16 mg/d C: 2-6 y: PO: 0.25 mg/kg/d in divided doses; *max:* 12 mg/d	For allergies (rhinitis, conjunctivitis, pruritus). Common side effects include drowsiness, dry mouth, dizziness, and epigastric distress. Pregnancy category: B; PB: UK; t½: 1-4 h
Piperazine Derivatives		
levocetirizine (Xyzal)	A/C>12 y: PO: 2.5-5 mg once daily in evening C: 6-11 y: PO: 1.25-2.5 mg once daily in evening	For allergic rhinitis, chronic urticaria. Common side effects include drowsiness, fatigue, and weakness. Pregnancy category: B; PB: 91%-92%; t½: 8-9 h
Other Antihistamines		
codeine, triprolidine and pseudoephedrine (Triacin-C)	Codeine 10 mg, triprolidine 2 mg, pseudoephedrine 30 mg in 5-mL oral syrup A: PO: 10 mL q4-6h; *max:* 20 mL/d C: 6-12 y: PO: 5 mL q4-6h; Codeine 20 mg, triprolidine 4 mg, pseudoephedrine 60 mg in oral tablet A/C: >12y: PO: 1 tab q6h	For rhinitis. Combination of an antihistamine and decongestant. Pregnancy category: C; PB: UK; t½: 3 h
azelastine and fluticasone (Dymista)	A: nasal spray: 1 spray per nostril b.i.d.	For seasonal allergic rhinitis. Most common side effect is bad taste. Pregnancy category: C; PB: 88%-97%; t½: 8-25 h
Second-Generation Antihistamines		
azelastine (Astelin)	Nasal spray: A/C ≥12 y: 1-2 sprays in each nostril q12h C: <11 y: 1 spray in each nostril b.i.d.	For allergic rhinitis. May cause headaches, mild sedation, and bitter taste. Pregnancy category: C; PB: 88%; t½: 22 h
cetirizine (Zyrtec)	A/C: >6 y: PO: 5-10 mg/d Older adults: PO: 5 mg/d	For allergic rhinitis and urticaria. Has few anticholinergic effects. Pregnancy category: B; PB: 93%; t½: 8 h
fexofenadine (Allegra) with pseudoephedrine (Allegra-D)	Fexofenadine 180 mg, pseudoephedrine 240 mg (Allegra-D 24-Hour) A/C: ≥12 y: PO: 1 tab once daily	For allergic rhinitis and rhinorrhea. Has less sedative effect. Pregnancy category: C; PB: 60%-70%; t½: 14.4 h
loratadine (Claritin)	A/C: >6 y: PO: 10 mg/d	For allergic rhinitis and urticaria. Long-acting H_1-blocking effect. Pregnancy category: UK; PB: 97%; t½: 12-15 h
desloratadine (Clarinex)	A/C: >12 y: PO: 5 mg/d C: 6-12 y: PO: 2.5 mg/d C: 2-5 y: PO: 1.25 mg/d	For allergic rhinitis. Pregnancy category: C; PB: 82%-87%; t½: 27 h

A, Adult; *b.i.d.*, twice a day; *C*, child; *d*, day; *h*, hour; *h.s.*, at bedtime; *IM*, intramuscular; *IV*, intravenous; *max*, maximum; *mo*, month; *PB*, protein-binding; *PO*, by mouth; *q.i.d.*, four times a day; *subQ*, subcutaneous; *SR*, sustained-release; *t½*, half-life; *tab*, tablet; *t.i.d.*, three times a day; *UK*, unknown; *y*, year; *>*, greater than; *<*, less than.

Nursing Interventions

- Give oral form with food to decrease gastric distress.
- Administer IM form in large muscle. *Avoid subQ injection.*

Patient Teaching

General

- Warn patient to avoid driving a motor vehicle and performing other dangerous activities if drowsiness occurs or until stabilized on drug.
- Advise patient to avoid alcohol and other central nervous system depressants.
- Encourage patient to take drug as prescribed. Notify health care provider if confusion or hypotension occurs.
- Teach patient on prophylaxis for motion sickness to take drug at least 30 minutes before offending event and also before meals and at bedtime during event.
- Inform breastfeeding mothers that small amounts of drug pass into breast milk. Because children are more susceptible to side effects of antihistamines (e.g., unusual excitement or irritability), breastfeeding is not recommended while using these drugs.

Side Effects

- Advise family members or parents that children are more sensitive to effects of antihistamines. Nightmares, nervousness, and irritability are more likely to occur in children.
- Inform older adults that they are more sensitive to effects of antihistamines and are more likely to experience confusion, difficult or painful urination, dizziness, drowsiness, feeling faint, and dryness of mouth, nose, or throat.
- Suggest using sugarless candy or gum, ice chips, or a saliva substitute for temporary relief of mouth dryness.

Cultural Considerations

- Decrease language barriers by decoding jargon used in the health care environment for those with language difficulties and those who are not in the health care field.

Evaluation

- Evaluate effectiveness of drug in relieving allergic symptoms or as a sleep aid.

Systemic decongestants (alpha-adrenergic agonists) are available in tablet, capsule, and liquid form and are used primarily for allergic rhinitis, including hay fever and acute coryza (profuse nasal discharge). Examples of systemic decongestants are ephedrine (Ephedrine), phenylephrine (Neo-Synephrine), and pseudoephedrine (Sudafed). In the past, phenylpropanolamine was used in many cold remedies; however, the U.S. Food and Drug Administration (FDA) ordered its removal from OTC cold remedies and weight-loss aids because reports suggest that the drug might cause stroke, hypertension, renal failure, and cardiac dysrhythmias. Ephedrine, phenylephrine, and pseudoephedrine are frequently combined with an antihistamine, analgesic, or antitussive in oral cold remedies. The advantage of systemic decongestants is that they relieve nasal congestion for a longer period than nasal decongestants; however, currently there are long-acting nasal decongestants. Nasal decongestants usually act promptly and cause fewer side effects than systemic decongestants. Table 40-2 lists systemic and nasal decongestants and their dosages, uses, and considerations.

Side Effects and Adverse Reactions

The incidence of side effects is low with topical preparations such as nose drops. Decongestants can make a patient jittery, nervous, or restless. These side effects decrease or disappear as the body adjusts to the drug.

Use of nasal decongestants for as little as 3 days could result in rebound nasal congestion. Instead of the nasal membranes constricting, vasodilation occurs, causing increased stuffy nose and nasal congestion. The nurse should emphasize the importance of limiting the use of nasal sprays and drops.

As with any alpha-adrenergic drug (e.g., decongestants), blood pressure and blood glucose levels can increase. These drugs are contraindicated or used with extreme caution in patients with hypertension, cardiac disease, hyperthyroidism, and diabetes mellitus.

Drug Interactions

When using decongestants with other drugs, drug interactions can occur. Pseudoephedrine may decrease the effect of beta blockers. Taken together with monoamine oxidase inhibitors (MAOIs), decongestants may increase the possibility of hypertension or cardiac dysrhythmias. The patient should also avoid large amounts of caffeine (coffee, tea) because it can increase restlessness and palpitations caused by decongestants.

Intranasal Glucocorticoids

Intranasal glucocorticoids or steroids are effective for treating allergic rhinitis. Because these agents are steroids, they have an antiinflammatory action, thus decreasing the allergic rhinitis symptoms of rhinorrhea, sneezing, and congestion. The following are examples of intranasal steroids:

- Beclomethasone (Beconase)
- Budesonide (Pulmicort, Rhinocort)
- Dexamethasone (Decadron)
- Flunisolide
- Fluticasone (Flonase, Flovent)
- Triamcinolone (Nasacort AQ)

These drugs may be used alone or in combination with an H_1 antihistamine. With continuous use, dryness of the nasal mucosa may occur.

TABLE 40-2 SYSTEMIC AND NASAL DECONGESTANTS (SYMPATHOMIMETIC AMINES)

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
ephedrine HCl (Primatene)	Bronchospasm: A: PO: 25-50 mg t.i.d./q.i.d. PRN; *max:* 150 mg/d A: subQ/IM/IV: 12.5-25 mg; may repeat; *max:* 150 mg once daily C: PO: 6-12 y: 2-3 mg/kg/d in 4-6 divided doses; *max:* 3 mg/kg/d Nasal spray for nasal congestion: A/C: >12 y: 2-3 sprays in each nostril q4h PRN C: 6-12 y: 1-2 sprays q4h PRN	For nasal congestion, asthma; acute bronchospasm, improves opioid-impaired respiration; corrects hypotension. Alpha- and beta-adrenergic agonist. OTC drug used alone or in combination. Pregnancy category: C; PB: UK; t½: 3-6 h
naphazoline HCl (Privine)	A/C: >12 y: 1-2 sprays 0.05% spray in each nostril q4-6h	For nasal congestion and allergic rhinitis. Can cause rebound congestion, transient hypertension, bradycardia, and cardiac dysrhythmias. Pregnancy category: C; PB: UK; t½: UK
oxymetazoline HCl (Afrin)	A/C: >6 y: 0.05% gtt or spray; 1-2 sprays in each nostril b.i.d. C: 2-5 y (0.025% solution only): 2-3 gtt b.i.d.	Long-acting decongestant. Taken twice a day (morning and evening). Can cause rebound congestion. Use only for 3-5 d. Pregnancy category: C; PB: UK; t½: UK
phenylephrine HCl (Neo-Synephrine Nasal)	A: sol (0.25%-1%): 2-3 sprays in each nostril q4h	For rhinitis. Less potent than epinephrine. Can cause transient hypertension and headaches. Use only for 3-5 d. Pregnancy category: C; PB: UK; t½: 2.5 d
pseudoephedrine (Sudafed)	A: PO: 60 mg q4-6h; SR 120 mg q12h; *max:* 240 mg/d C: 6-12 y: 30 mg q4-6h; *max:* 120 mg/d C: 2-5 y: 15 mg q4-6h; *max:* 60 mg/d	For rhinitis. Less CNS stimulation and hypertension than ephedrine. Pregnancy category: C; PB: UK; t½: 9-15 h
tetrahydrozoline (Tyzine)	A/C: >6 y: Nasal: 2-4 sprays in each nostril q3h PRN C: 2-6 y: Nasal: 2-3 sprays in each nostril q3h PRN	For nasopharyngeal congestion. Pregnancy category: C; PB: UK; t½: UK

A, Adult; *b.i.d.,* twice a day; *C,* child; *CNS,* central nervous system; *d,* day; *gtt,* drops; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *OTC,* over-the-counter; *PB,* protein-binding; *PO,* by mouth; *PRN,* as necessary; *q.i.d.,* four times a day; *sol,* solution; *subQ,* subcutaneous; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *y,* year; >, greater than; <, less than.

It is rare for systemic effects of steroids to occur, but they are more likely to result with the use of intranasal dexamethasone, which should not be used for longer than 30 days. The other intranasal glucocorticoids undergo rapid deactivation after absorption. Most allergic rhinitis is seasonal; therefore the drugs are for short-term use unless otherwise indicated by the health care provider. Table 40-3 lists the intranasal glucocorticoids and their dosages, uses, and considerations.

Antitussives

Antitussives act on the cough-control center in the medulla to suppress the cough reflex. The cough is a naturally protective way to clear the airway of secretions or any collected material. A sore throat may cause coughing that increases throat irritation. If the cough is nonproductive and irritating, an antitussive may be taken. Hard candy may decrease the constant, irritating cough. Dextromethorphan, a nonnarcotic antitussive, is widely used in OTC cold remedies. Prototype Drug Chart 40-2 lists the drug data related to dextromethorphan (Benylin DM).

The three types of antitussives are nonnarcotic, narcotic, or combination preparations. Antitussives are usually used in combination with other agents (Table 40-4).

Pharmacokinetics Dextromethorphan is available in numerous cold and cough remedy preparations in syrup or liquid form, chewable capsules, and lozenges. Brand name formulations include Robitussin, and Sucrets. The drug is rapidly absorbed and exerts its effects 15 to 30 minutes after oral administration. Its protein-binding percentage is unknown, and the half-life is 11 hours. Dextromethorphan is metabolized by the liver and excreted in the urine.

Pharmacodynamics Dextromethorphan, a nonnarcotic antitussive, suppresses the cough center in the medulla but does not depress respiration. It causes neither physical dependence nor tolerance. The patient should notify the health care provider and seek medical care if the cough lasts longer than 1 week and a fever or rash is present. Patients with underlying medical conditions should seek prompt medical attention.

The onset of action for dextromethorphan is relatively fast, and its duration is 3 to 6 hours. Usually preparations containing dextromethorphan can be used several times a day. CNS depression may occur if the drug is used with alcohol, opioids, sedative-hypnotics, barbiturates, or antidepressants.

Expectorants

Expectorants loosen bronchial secretions so they can be eliminated by coughing. They can be used with or without other pharmacologic agents. Expectorants are found in many OTC cold remedies along with analgesics, antihistamines, decongestants, and antitussives. The most common expectorant in such preparations is guaifenesin. Hydration is the best natural expectorant. When taking an expectorant, patients should increase fluid intake to at least 8 glasses per day to help loosen mucus. Table 40-4 lists the dosages, uses, and considerations for antitussives and expectorants.

TABLE 40-3 INTRANASAL GLUCOCORTICOIDS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
beclomethasone (Beconase AQ, Qnasl)	A: 1-2 puffs/sprays b.i.d. C: 6-12 y: 1 spray b.i.d.	For seasonal or perennial allergic and nonallergic rhinitis. Pregnancy category: C; PB: 87%; t½: 15 h
budesonide (Pulmicort, Rhinocort)	A/C: >6 y: 1-2 sprays b.i.d. or 4 sprays in the morning	For seasonal rhinitis in adults and children. Maintenance therapy for asthma. Pregnancy category: C; PB: 90%; t½: 2.5-3 h
dexamethasone (Decadron)	A/C: 6-12 y: 1-2 sprays b.i.d.	For allergic and inflammatory conditions. Administered orally, intravenously, ophthalmically, topically, and intranasally. A potent steroid used for short-term therapy. May have a systemic effect. Pregnancy category: C; PB: UK; t½: 2-3.5 h
flunisolide	A: 2 sprays b.i.d./t.i.d. C: 6-14 y: 1 spray t.i.d. or 2 sprays b.i.d.	For seasonal rhinitis in adults and children. May be used for steroid-dependent asthma. Pregnancy category: C; PB: UK; t½: 1-2 h
fluticasone (Flonase, Flovent)	A: 2 sprays once daily or 1 spray b.i.d. C: >6 y: 1 spray/d	For seasonal allergic rhinitis. When symptoms decrease, reduce dose to 1 spray daily. Pregnancy category: C: PB: 91%; t½: 8 h
mometasone furoate (Nasonex)	A: 2 sprays once daily C: 1 spray once daily	For seasonal allergic rhinitis. Pregnancy category: C; PB: UK; t½: UK Note: Direct spray away from nasal septum; gently sniff.
triamcinolone (Nasacort AQ)	A/C: 1-2 sprays once daily	For allergic rhinitis. Has many uses, such as an immunosuppressant. Pregnancy category: C; PB: UK; t½: 2-5 h

A, Adult; *b.i.d.,* twice a day; *C,* child; *h,* hour; *PB,* protein-binding; *q.i.d.,* four times a day; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *y,* year; *>,* greater than.

PROTOTYPE DRUG CHART 40-2

Dextromethorphan Hydrobromide

Drug Class
Antitussive
Trade Names: Robitussin, Sucrets, Benylin DM
Pregnancy Category: UK

Dosage
A: PO: 10-20 mg q4h; *max:* 120 mg/d
C: 6-12 y: PO: 5-10 mg q4h; *max:* 60 mg/d
C: 2-5 y: PO: 2.5-5.0 mg q4h; *max:* 30 mg/d

Contraindications
Chronic obstructive pulmonary disease, chronic productive cough, hypersensitivity; children <2 y

Drug-Lab-Food Interactions
Drug: Increase effect/toxicity with MAOIs, SSRIs, SNRIs, opioids, sedative-hypnotics, barbiturates, antidepressants, and alcohol
Food: Grapefruit juice can increase risk of toxicity.

Pharmacokinetics
Absorption: PO: Rapidly absorbed
Distribution: PB: UK
Metabolism: t½: 11 h
Excretion: In urine

Pharmacodynamics
PO: Onset: 15-30 min
Peak: UK
Duration: 3-6 h

Therapeutic Effects/Uses
To provide temporary suppression of nonproductive cough; to reduce viscosity of tenacious secretions
Mode of Action: Inhibits cough center in the medulla

Side Effects
Nausea, dizziness, drowsiness, fatigue, sedation

Adverse Reactions
Hallucinations (high doses)

A, Adult; *C,* child; *d,* day; *h,* hour; *MAOIs,* monoamine oxidase inhibitors; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *y,* year.

Nursing Process
Patient-Centered Collaborative Care

Common Cold

Assessment

- Determine whether there is a history of hypertension, especially if a decongestant is an ingredient in the cold remedy.
- Note baseline vital signs. An elevated temperature of 99°F to 101°F (37.2°C to 38.3°C) may indicate a viral infection caused by a cold.
- Obtain drug history; report if drug-drug interaction is probable. Dextromethorphan HCl given with MAOIs, narcotics, sedative-hypnotics, barbiturates, antidepressants, and alcohol may increase toxicity.
- Assess cardiac and respiratory status.

TABLE 40-4 ANTITUSSIVES AND EXPECTORANTS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Opioid Antitussives		
codeine CSS II	A: PO: 10-20 mg q4-6h; *max:* 120 mg/d	Schedule II drug. Can be Schedule V when combined in cough syrup. Usually mixed with antihistamine, decongestant, and/or expectorant. Can cause drowsiness, dizziness, nausea, constipation, and respiratory depression. Pregnancy category: C; PB: 7%; t½: 3-4 h
guaifenesin and codeine (Cheratussin AC, Tussi-Organidin NR) CSS V	Guaifenesin 300 mg, codeine 10 mg per 5 mL A: PO: 5 mL q4h; *max:* 60 mL/d (codeine 120 mg) C: 6-12 y: PO: 2.5 mL q4-6h; *max:* 20 mL/d C: 2-6 y: PO: 2.5 mL q4-6h; *max:* 6 mL/d	An expectorant combined with an opioid antitussive. Also used to control cough caused by bronchitis or common cold. Pregnancy category: C; PB: UK; t½: 1-4 h
homatropine and hydrocodone (Tussigon, Mycodone) CSS III	A: PO: 5-10 mg q4-6h; *max:* 15 mg/d C: >6y: PO: 2.5 mg q4-6h	Relief of cough and pain. Similar side effects as codeine. Pregnancy category: C; PB: UK; t½: 3-4 h
Nonopioid Antitussives		
benzonatate (Tessalon Perles)	A/C: >10 y: PO: 100 mg t.i.d. PRN; *max:* 600 mg/d	Relief of nonproductive cough without respiratory depression. Pregnancy category: C; PB: UK; t½: UK
dextromethorphan hydrobromide (Benylin DM)	See Prototype Drug Chart 40-2.	
promethazine with dextromethorphan	A: PO: 5 mL q4-6h; *max:* 30 mL/d C: 6-12 y: PO: 2.5-5 mL q4-6h; *max:* 20 mL/d C: 2-6 y: PO: 1.25-2.5 mL, q4-6h; *max:* 10 mL/d	For cough. Combination of a phenothiazine and nonnarcotic antitussive. Pregnancy category: C; PB: 80%-93%; t½: 10-14 h
Expectorants		
guaifenesin (Robitussin)	A: PO: 200-400 mg q4h; *max:* 2.4 g/d C: 6-12 y: PO: 100-200 mg q4h; *max:* 1.2 g/d C: 2-5 y: PO: 50-100 mg q4h; *max:* 600 mg/d	For dry, unproductive cough. Can cause nausea and vomiting. May be combined with other cold remedies. Take with water to loosen mucus. Pregnancy category: C; PB: UK; t½: 1 h
Antitussive/Expectorant		
guaifenesin and dextromethorphan (Robitussin-DM)	A: PO: 20-30 mL q4h PRN C: 6-12 y: PO: 10 mL q4h PRN C: 2-5 y: PO: 5 mL q4h PRN	For nonproductive cough. Pregnancy category: C; PB: UK; t½: UK

A, Adult; *C,* child; *CSS,* Controlled Substances Schedule; *d,* day; *h,* hour; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *PRN,* as necessary; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *y,* year; *<,* less than.

Nursing Diagnoses

- Ineffective airway clearance related to nasal congestion
- Risk for imbalanced fluid volume related to excessive sweating and loss of fluids
- Sleep deprivation related to chronic coughing
- Fatigue related to sleep deprivation
- Risk for infection related to insufficient knowledge to avoid exposure to pathogens

Planning

- Patient will be free from nonproductive cough.
- Patient will be free from a secondary bacterial infection.

Nursing Interventions

- Monitor vital signs. Blood pressure can become elevated when a decongestant is taken. Dysrhythmias can also occur.
- Observe color of bronchial secretions. Yellow or green mucus is indicative of a bronchial infection. Antibiotics may be needed.
- Warn patient that codeine preparations for cough suppression can lead to tolerance and physical dependence.

Patient Teaching

General

- Tell patient that hypotension and hyperpyrexia may occur when dextromethorphan is taken with MAOIs.
- Teach patient about proper use of a nasal spray and proper use of "puff" or squeeze products.
- Caution patient not to use more than one or two puffs, four to six times a day, for 5 to 7 days. Rebound congestion can occur with overuse.
- Advise patient to read labels on OTC drugs and to check with health care provider before taking cold remedies.

This is especially important when taking other drugs or when patient has a major health problem such as hypertension or hyperthyroidism. Also, acetaminophen may be in many products, promoting an overdose.

- Inform patient that antibiotics are not helpful in treating common cold viruses. However, they may be prescribed if a secondary infection occurs.
- Encourage older patient with heart disease, asthma, emphysema, diabetes mellitus, or hypertension to contact the health care provider concerning the selection of drug, including OTC drugs.
- Direct patient not to drive during initial use of a cold remedy containing an antihistamine because drowsiness is common.
- Tell patient to maintain adequate fluid intake. Fluids liquefy bronchial secretions to ease elimination with coughing.
- Teach patient not to take a cold remedy before or at bedtime. Insomnia may occur if it contains a decongestant.
- Encourage patient to get adequate rest.
- Inform patient that common cold and flu viruses are transmitted frequently by hand-to-hand contact or by touching a contaminated surface. Cold viruses can live on the skin for several hours and on hard surfaces for several days.
- Advise patient to avoid environmental pollutants, fumes, smoking, and dust to lessen irritating cough.
- Teach patient to perform three effective coughs before bedtime to promote uninterrupted sleep.
- Direct patient and parents to store drug out of reach of children; request childproof caps.
- Advise patient to contact health care provider if cough persists for more than 1 week or is accompanied by chest pain, fever, or headache.

Self-Administration

- Teach patient to self-administer medications such as nose drops and inhalants.
- Encourage patient to cough effectively, to take deep breaths before coughing, and to be in the upright position.

Cultural Considerations

- Allow patient to incorporate traditional remedies for treating common cold into prescribed Western medical practices (if remedies are harmless). Discuss practices that could cause harm.
- Identify conflicts in values and beliefs in treatment of common cold.
- Respectfully present treatment methods to care for the common cold for patients from various cultural backgrounds, such as increasing fluid intake, getting adequate rest, and using disposable tissues to remove nasal and bronchial secretions.
- Advise patient to contact a health professional if cold persists and if body temperature is greater than 101°F (38.3°C).

Evaluation

- Evaluate effectiveness of drug therapy. Determine that patient is free from nonproductive cough, has adequate fluid intake and rest, and is afebrile.

SINUSITIS

Sinusitis is an inflammation of the mucous membranes of one or more of the maxillary, frontal, ethmoid, or sphenoid sinuses. A systemic or nasal decongestant may be indicated. Acetaminophen, fluids, and rest may also be helpful. For acute or severe sinusitis, an antibiotic may be prescribed.

ACUTE PHARYNGITIS

Acute pharyngitis (inflammation of the throat, or "sore throat") can be caused by a virus, beta-hemolytic streptococci (strep throat), or other bacteria. It can occur alone or with the common cold and rhinitis or acute sinusitis. Symptoms include elevated temperature and cough. A throat culture should be obtained to rule out beta-hemolytic streptococcal infection. If the culture is positive for beta-hemolytic streptococci, a 10-day course of antibiotics is often prescribed. Saline gargles, lozenges, and increased fluid intake are usually indicated. Acetaminophen may be taken to decrease elevated temperature. Antibiotics are not effective for viral pharyngitis.

Information on loratadine: *www.medicinenet.com/loratadine/article.htm*

CRITICAL THINKING CASE STUDY

GH, a 35-year-old patient, has allergic rhinitis. Her prescriptions include loratadine (Claritin) 5 mg/day and fluticasone (Flonase, Flovent) two nasal inhalations/day. Previously she had taken OTC drugs and asked if she should continue to take the OTC drug with her prescriptions. She has never used a nasal inhaler.

1. What additional information is needed from GH concerning her health problem?
2. What is your response to GH concerning the use of OTC drugs with her prescription drugs?
3. How would you instruct GH to use a nasal inhaler? Explain your answer.
4. What are the similarities and differences between loratadine and diphenhydramine? Could one of these antihistamines be more effective than the other? Explain your answer.
5. Design a patient teaching plan for GH in regard to medications and environmental allergens.
6. What could you suggest to decrease allergens (e.g., dust mites) in the home?

NCLEX STUDY QUESTIONS

1. A patient tells the nurse that he has started to take an over-the-counter (OTC) antihistamine, diphenhydramine (Benadryl). In teaching about side effects, what is most important for the nurse to tell the patient?
   a. Do not to take this drug at bedtime to avoid insomnia.
   b. Avoid driving a motor vehicle until stabilized on the drug.
   c. Nightmares and nervousness are more likely in an adult.
   d. Medication may cause him to have excessive secretions.
2. A patient complains of a sore throat and has been told it is due to beta-hemolytic streptococcal infection. The nurse anticipates that the patient has which acute condition?
   a. Rhinitis
   b. Sinusitis
   c. Pharyngitis
   d. Rhinorrhea
3. A patient is prescribed the decongestant oxymetazoline (Afrin) nasal spray. What will the nurse teach the patient?
   a. Take this drug at bedtime because it may cause drowsiness.
   b. Directly spray the medication away from the nasal septum, and gently sniff.
   c. This drug may be used in maintenance treatment for asthma.
   d. Limit use of the drug to 5 to 7 days to prevent rebound nasal congestion.
4. A patient has been prescribed guaifenesin (Robitussin). The nurse understands that the purpose of the drug is to accomplish what?
   a. Treat allergic rhinitis and prevent motion sickness.
   b. Loosen bronchial secretions so coughing can eliminate them.
   c. Compete with histamine for receptor sites, thus preventing a histamine response.
   d. Stimulate alpha-adrenergic receptors, thus producing vascular constriction of capillaries in nasal mucosa.
5. Beclomethasone (Beconase) has been prescribed for a patient with allergic rhinitis. What should the nurse teach the patient regarding this medication?
   a. This may be used for an acute attack.
   b. An oral form is available if the patient prefers to use it.
   c. Avoid large amounts of caffeine intake because an increased heart rate may occur.
   d. With continuous use, dryness of the nasal mucosa/lining may occur.
6. The nurse is teaching a patient about diphenhydramine (Benadryl). Which instructions should the nurse include in the patient's teaching plan? (Select all that apply.)
   a. Take medication on an empty stomach to facilitate absorption.
   b. Avoid alcohol and other central nervous system depressants.
   c. Notify the health care provider if confusion or hypotension occurs.
   d. Use sugarless candy, gum, or ice chips for temporary relief of dry mouth.
   e. Avoid handling dangerous equipment or performing dangerous activities until stabilized on the medication.

OBJECTIVES

- Compare chronic obstructive pulmonary disease (COPD) and restrictive lung disease.
- Differentiate the drug groups used to treat COPD and asthma and the desired effects of each.
- Compare the side effects of beta$_2$-adrenergic agonists and methylxanthines.
- Describe the therapeutic serum or plasma theophylline level and the toxic level.
- Contrast the therapeutic effects of leukotriene antagonists, glucocorticoids, cromolyn, antihistamines, and mucolytics for COPD and asthma.
- Apply the nursing process for the patient taking drugs commonly used for COPD, including asthma, and restrictive lung disease.

OUTLINE

Chronic Obstructive Pulmonary Disease
  Bronchial Asthma
Sympathomimetics: Alpha- and Beta$_2$-Adrenergic Agonists
  Albuterol
  Metaproterenol
  Isoproterenol
  Use of an Aerosol Inhaler
Anticholinergics
Methylxanthine (Xanthine) Derivatives
  Theophylline
  Nursing Process: Patient-Centered Collaborative Care: Bronchodilators
Leukotriene Receptor Antagonists and Synthesis Inhibitors
  Nursing Process: Patient-Centered Collaborative Care: Leukotrine Receptor Antagonists
Glucocorticoids (Steroids)
Cromolyn and Nedocromil
Drug Therapy for Asthma According to Severity
Drug Therapy for Asthma According to Age

restrictive lung disease, p. 584

Chronic obstructive pulmonary disease (COPD) and restrictive pulmonary disease are the two major categories of lower respiratory tract disorders. COPD is caused by airway obstruction with increased airway resistance of air flow to lung tissues. Four major pulmonary disorders cause COPD: chronic bronchitis, bronchiectasis, emphysema, and asthma. Chronic bronchitis, bronchiectasis, and emphysema frequently result in irreversible lung tissue damage. The lung tissue changes resulting from an acute asthmatic attack are normally reversible; however, if the attacks are frequent and asthma becomes chronic, irreversible changes in the lung tissue may result. Patients with COPD usually have a decrease in forced expiratory volume in 1 second (FEV_1) as measured by pulmonary function tests.

Restrictive lung disease is a decrease in total lung capacity as a result of fluid accumulation or loss of elasticity of the lung. Pulmonary edema, pulmonary fibrosis, pneumonitis, lung tumors, thoracic deformities (scoliosis), and disorders affecting the thoracic muscular wall (e.g., myasthenia gravis) are among the types and causes of restrictive pulmonary disease.

Drugs discussed in this chapter are primarily used to treat COPD, particularly asthma. These drugs include **bronchodilators** (sympathomimetics [primarily beta_2-adrenergic agonists], methylxanthines [xanthines]), leukotriene antagonists, glucocorticoids, cromolyn, anticholinergics, and mucolytics. Some of these drugs may also be used to treat restrictive pulmonary diseases.

CHRONIC OBSTRUCTIVE PULMONARY DISEASE

Asthma is an inflammatory disorder of the airway walls associated with a varying amount of airway obstruction. This disorder is triggered by stimuli such as stress, allergens, and pollutants. When activated by stimuli, the bronchial airways become inflamed and edematous, leading to constriction of air passages. Inflammation aggravates airway hyperresponsiveness to stimuli, causing bronchial cells to produce more mucous, which obstructs air passages. This obstruction contributes to wheezing, coughing, dyspnea (breathlessness), and tightness in the chest, particularly at night or in the early morning.

Bronchial asthma, one of the COPD lung diseases, is characterized by bronchospasm (constricted bronchioles), wheezing, mucus secretions, and dyspnea. There is resistance to air flow caused by obstruction of the airway. In acute and chronic asthma, minimal to no changes are seen in the structure and function of lung tissues when the disease process is in remission. In chronic bronchitis, emphysema, and bronchiectasis, there is permanent, irreversible damage to the physical structure of lung tissue. Symptoms are similar to those of asthma in these three pulmonary disorders, except wheezing does not occur. Figure 41-1 shows the overlapping symptoms of COPD conditions. Frequently, there is a steady deterioration over a period of years.

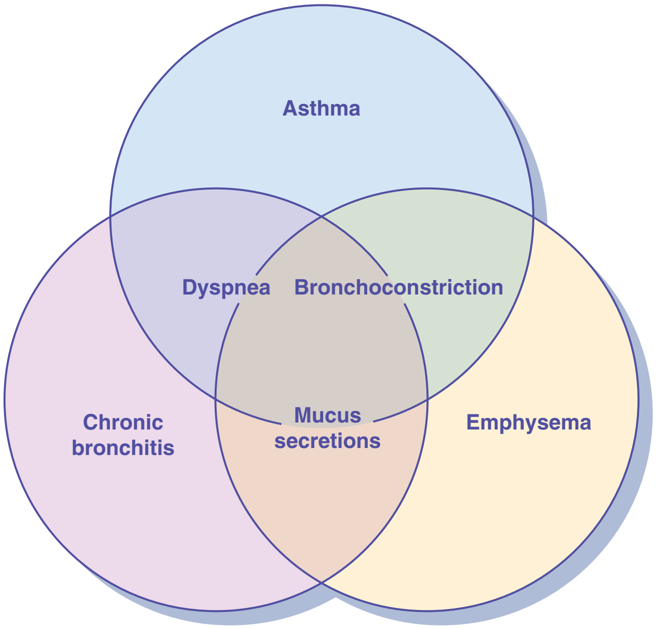

FIGURE 41–1 Overlapping signs and symptoms of chronic obstructive pulmonary disease (COPD) conditions.

Chronic bronchitis is a progressive lung disease caused by smoking or chronic lung infections. Bronchial inflammation and excessive mucous secretion result in airway obstruction. Productive coughing is a response to excess mucus production and chronic bronchial irritation. Inspiratory and expiratory rhonchi may be heard on auscultation. Hypercapnia (increased carbon dioxide retention) and hypoxemia (decreased blood oxygen) lead to respiratory acidosis.

In **bronchiectasis,** there is abnormal dilation of the bronchi and bronchioles secondary to frequent infection and inflammation. The bronchioles become obstructed by the breakdown of the epithelium of the bronchial mucosa. Tissue fibrosis may result.

Emphysema is a progressive lung disease caused by cigarette smoking, atmospheric contaminants, or lack of the alpha_1-antitrypsin protein that inhibits proteolytic enzymes that destroy alveoli (air sacs). Proteolytic enzymes are released in the lung by bacteria or phagocytic cells. The terminal bronchioles become plugged with mucus, causing a loss in the fiber and elastin network in the alveoli. Alveoli enlarge as many of the alveolar walls are destroyed. Air becomes trapped in the overexpanded alveoli, leading to inadequate gas (oxygen and carbon dioxide) exchange.

Cigarette smoking is the most common risk factor for COPD, especially with chronic bronchitis and emphysema. There is no cure for COPD at this time; however, it remains preventable in most cases. Because cigarette smoking is the most directly related cause, not smoking significantly prevents COPD from developing. Quitting smoking will slow the disease process.

Medications frequently prescribed for COPD include the following:

- Bronchodilators such as sympathomimetics (adrenergics), parasympatholytics (anticholinergic drug, Atrovent), and methylxanthines (caffeine, theophylline) are used to assist in opening narrowed airways.

- Glucocorticoids (steroids) are used to decrease inflammation.
- Leukotriene modifiers reduce inflammation in the lung tissue, and cromolyn and nedocromil act as antiinflammatory agents by suppressing the release of histamine and other mediators from the mast cells.
- Expectorants are used to assist in loosening mucus from the airways.
- Antibiotics may be prescribed to prevent serious complications from bacterial infections.

See the Key Websites at the end of the chapter for recommended methods for smoking cessation.

Bronchial Asthma

Bronchial asthma is a COPD characterized by periods of bronchospasm resulting in wheezing and difficulty breathing. **Bronchospasm,** or bronchoconstriction, results when the lung tissue is exposed to extrinsic or intrinsic factors that stimulate a bronchoconstrictive response. Factors that can trigger an asthmatic attack (bronchospasm) include humidity; air pressure changes; temperature changes; smoke; fumes (exhaust, perfume); stress; emotional upset; exercise; and allergies to animal dander, dust mites, food, and drugs (e.g., aspirin, ibuprofen, beta-adrenergic blockers). Reactive airway disease (RAD) is a cause of asthma resulting from sensitivity stimulation from allergens, dust, temperature changes, and cigarette smoking.

Pathophysiology

Mast cells, found in connective tissue throughout the body, are directly involved in the asthmatic response, particularly to extrinsic factors. Allergens attach themselves to mast cells and basophils, resulting in an antigen-antibody reaction on the mast cells in the lung; thus the mast cells stimulate the release of chemical mediators such as histamines, cytokines, serotonin, eosinophil chemotactic factor of anaphylaxis (ECF-A), and leukotrienes. Eosinophil counts are usually elevated during an allergic reaction, which indicates that an inflammatory process is occurring. These chemical mediators stimulate bronchial constriction, mucous secretions, inflammation, and pulmonary congestion. Histamine and ECF-A are strong bronchoconstrictors. Bronchial smooth muscles are wrapped spirally around the bronchioles and contract as they are stimulated by these mediators. Exposure to an allergen results in bronchial hyperresponsiveness, epithelial shedding of the bronchial wall, mucous gland hyperplasia and hypersecretion, leakage of plasma leading to swelling, and bronchoconstriction.

Figure 41-2 shows factors contributing to bronchoconstriction. Cyclic adenosine monophosphate (cyclic AMP, or cAMP), a cellular signaling molecule, is involved in many cellular activities and is responsible for maintaining bronchodilation. When histamine, ECF-A, and leukotrienes inhibit the action of cAMP, bronchoconstriction results. The sympathomimetic (adrenergic) bronchodilators and methylxanthines increase the amount of cAMP in bronchial tissue cells.

Increased bronchial secretions

FIGURE 41–2 Factors contributing to bronchoconstriction.

In an acute asthmatic attack, the short-acting sympathomimetics (beta$_2$-adrenergic agonists) are the first line of defense. They promote cAMP production and enhance bronchodilation. Long-acting sympathomimetics are used for maintenance. Sympathomimetics (adrenergics) are also discussed in Chapter 18.

SYMPATHOMIMETICS: ALPHA- AND BETA$_2$-ADRENERGIC AGONISTS

Sympathomimetics increase cAMP, causing dilation of the bronchioles. In an acute bronchospasm caused by anaphylaxis from an allergic reaction, the nonselective sympathomimetic epinephrine (Adrenalin), which is an alpha$_1$, beta$_1$, and beta$_2$ agonist, is given subcutaneously to promote bronchodilation and elevate blood pressure. Epinephrine is administered in emergency situations to restore circulation and increase airway patency (see Chapter 59).

For bronchospasm associated with chronic asthma or COPD, selective beta$_2$-adrenergic agonists are given by aerosol or as a tablet. These drugs act primarily on the beta$_2$ receptors; therefore side effects are less severe than those of epinephrine, which acts on alpha$_1$, beta$_1$, and beta$_2$ receptors.

Albuterol

The newer beta-adrenergic drugs for asthma are more selective for beta$_2$ receptors. High doses or overuse of the beta$_2$-adrenergic agents for asthma may cause some degree of beta$_1$ response such as nervousness, tremor, and increased pulse rate. The ideal beta$_2$ agonist is one that has a rapid onset of action, longer duration of action, and few side effects. Albuterol (Proventil, Ventolin) is a selective beta$_2$ drug that is effective for treatment and control of asthma by causing bronchodilation with long duration of action. (See Prototype Drug Chart 18-2 for drug data related to albuterol.)

SAFETY: Preventing Medication Errors

Do not confuse…

- **albuterol** (beta$_2$-adrenergic) with **Accupril** (cardiovascular agent).

Metaproterenol

The second beta-adrenergic agent is metaproterenol (Alupent), which was first marketed in 1961. It has some beta$_1$ effect but is primarily used as a beta$_2$ agent. It can be administered orally or by inhalation with a metered-dose inhaler or a nebulizer.

For long-term asthma treatment, beta$_2$-adrenergic agonists are frequently administered by inhalation. This route of administration usually delivers more of the drug directly to the constricted bronchial site. The effective inhalation drug dose is less than it would be by the oral route, and there are also fewer side effects using this route. The onset of action of the drug is more rapid by inhalation (1 minute) than orally (15 minutes).

Isoproterenol

The first beta-adrenergic agent used for bronchospasm was isoproterenol (Isuprel), introduced in 1941. It has no alpha-agonist properties, but it is considered a nonselective beta agonist because it stimulates both beta$_1$ and beta$_2$ receptors. Beta$_1$ stimulation causes heart rate increases, and tachycardia may result. Beta$_2$ stimulation promotes bronchodilation. Isoproterenol is administered by inhalation, using an aerosol inhaler or nebulizer, or intravenously (IV) for severe asthmatic attacks. Its duration of action is short. Because of its severe side effects from beta$_1$ response, it is seldom prescribed.

SAFETY: Preventing Medication Errors

Do not confuse…

- **Isuprel** (beta-adrenergic) with **Isordil** (nitrate vasodilator).

Use of an Aerosol Inhaler

If the beta$_2$ agonist is given by metered-dose inhaler (MDI) or dry-powder inhaler (DPI), correct use of the inhaler and dosage intervals need to be explained to the patient. If the patient does not receive effective relief from the inhaler, either the technique is faulty or the canister is empty. A spacer device may be attached to the inhaler to improve drug delivery to the lung with less deposition in the mouth. If the patient does not use the inhaler properly to deliver the drug dose, the medication may be trapped in the upper airways. Because of drug inhalation, mouth dryness and throat irritation could result.

Excessive use of the aerosol drug can lead to tolerance and loss of drug effectiveness. Occasionally, severe paradoxical airway resistance (bronchoconstriction) develops with repeated, excessive use of sympathomimetic oral inhalation. Frequent dosing can cause tremors, nervousness, and increased heart rate. Table 41-1 lists the sympathomimetics used as bronchodilators.

Side Effects and Adverse Reactions

The side effects and adverse reactions of epinephrine include tremors, dizziness, hypertension, tachycardia, heart palpitations, cardiac dysrhythmias, and angina. The patient needs to be closely monitored when epinephrine is administered.

The side effects associated with beta$_2$-adrenergic drugs (e.g., albuterol) include tremors, headaches, nervousness, increased pulse rate, and palpitations (high doses). The beta$_2$ agonists may increase blood glucose levels, so patients with diabetes should be taught to closely monitor their serum glucose levels. Side effects of beta$_2$ agonists may diminish after 1 week or longer. The bronchodilating effects may decrease with continued use. It is believed that tolerance to these drugs

TABLE 41-1 ADRENERGIC BRONCHODILATORS AND ANTICHOLINERGICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Alpha- and Beta-Adrenergics		
ephedrine sulfate (Primatene) Alpha$_1$, beta$_1$, beta$_2$	A/C: >12 y: PO: 12.5 to 25 mg q4h; *max:* 150 mg/d; subQ/IM/IV: 25 to 50 mg	For nasal congestion, asthma, acute bronchospasm; improves respiration caused by narcotic excess; corrects hypotensive state. Nervousness, tachycardia, and insomnia could occur. Pregnancy category: C; PB: UK; t½: 3 h
epinephrine (EpiPen) Alpha$_1$, beta$_1$, beta$_2$	A: subQ: 0.2-1 mg of 1 : 1000 sol; may repeat q10-15min PRN C: subQ: 0.01 mg of 1 : 1000 sol; may repeat q15min-4h for 3-4 doses or q4h PRN	For acute bronchospasm and to combat anaphylaxis, angioedema, nasal congestion, status asthmaticus. Used frequently by nebulizer. Side effects include nervousness, tremors, dizziness, palpitations, tachycardia, and other cardiac dysrhythmias. Pregnancy category: C; PB: UK; t½: UK
Beta-Adrenergics		
albuterol (Proventil HFA, Ventolin HFA) Beta$_2$	A/C: >6 y: inhal MDI: 1 to 2 puffs q4-6h or 2 puffs 15 min before exercise A: PO immediate release: 2 to 4 mg t.i.d./q.i.d.; *max:* 32 mg/d A : PO:SR: 4 to 8 mg q12h; *max:* 32 mg/d C: 6 to 12 y: PO : immediate release: 2 mg t.i.d./q.i.d.; *max:* 24 mg/d C: 6 to 12 y: PO : SR: 4 to 8 mg q12h; *max:* 24 mg/d	For acute and chronic asthma, bronchitis, and exercise-induced bronchospasm. Onset of action orally is 30 min, and duration of action is 4 to 6 h (SR 8 to 12 h). Pregnancy category: C; PB: UK; t½: 4 to 6 h
isoproterenol (Isuprel) Beta$_1$ and beta$_2$	A/C: inhal: 1 to 2 puffs q4-6h; *max:* 12 inhal/d	For acute bronchospasm, COPD. Nonselective (beta$_1$ and beta$_2$). Beta$_1$ effect causes heart rate to increase. Monitor heart rate and blood pressure. Absorption of sublingual drug can be variable and unpredictable. Pregnancy category: C; PB: UK; t½: 2 to 5 min
levalbuterol (Xopenex HFA) Beta$_2$	Bronchospasm prophylaxis A/C: >12 y: nebulizer 0.63 to 1.25 mg q8h Acute bronchospasm A/C: >12yr: 1.25 to 2.5 mg q20min for 3 doses, then 1.25 to 5 mg q1-4h PRN; C: 6 to 11 yr: 0.75 mg/kg q20min for 3 doses, then 0.075 to 0.15 mg/kg q1-4h PRN	For acute bronchospasm and prevention of exercise-induced asthma. Product from albuterol derivative. Expensive. Rapid absorption and short acting. Side effects are nervousness and tremors. Pregnancy category: C; PB: UK; t½: 3.3 to 4 h
metaproterenol sulfate Beta$_1$ (some) and beta$_2$	A: PO: 20 mg t.i.d./q.i.d.; *max:* 80 mg/d	For acute bronchospasm, asthma, and COPD. Pregnancy category: C; PB: UK; t½: UK
formoterol fumarate (Foradil Aerolizer)	A/C: >5 y: inhal: Inhale contents of 1 capsule (12 mcg) q12h; *max:* 2 inhal/d	For asthma and prevention of exercise-induced asthma. Pregnancy category: C; PB: UK; t½: 10 h
salmeterol (Serevent Diskus) Beta$_2$	Maintenance bronchodilation A/C: > 4 y: Inhal: 1 puff q12h Prevention of exercise-induced bronchospasm A/C: >4 y: Inhal MDI: 1 puff at least 30 min before exercise	For chronic asthma and exercise-induced bronchospasm. Not effective for treating acute bronchospasm. Has a long duration of action (12 h). Pregnancy category: C; PB: 94% to 98%; t½: 5 h
terbutaline sulfate (Brethine) Beta$_2$	A: PO: 2.5 to 5 mg t.i.d.; *max:* 15 mg/d subQ: 0.25 to 0.5 mg q8h C: >12 y: PO: 2.5 mg t.i.d.; *max:* 7.5 mg/d	For reversible airway obstruction caused by asthma, bronchitis, acute bronchospasm, and emphysema. May cause nervousness, tremors, lightheadedness, palpitations, or tachycardia if taken in excess. Pregnancy category: C; PB: 25%; t½: 3 to 4 h
arformoterol tartrate (Brovana) Beta$_2$	A: inhal nebulizer: 15 mcg q12h; *max:* 30 mcg/d	For long-term maintenance treatment of COPD. Not effective for treating acute bronchospasm. Has a long duration of action. Pregnancy category: C; PB: 52% to 65%; t½: 26 h
indacaterol (Arcapta, Neohaler)	A: oral inhal: 75 mcg/d; max: 1 inhal/d	Long-acting beta$_2$ agonist to treat airflow obstruction from COPD. This maintenance bronchodilator should be administered at same time every dat. Most common adverse effects include post-inhalation cough and nasopharyngitis. Pregnancy category: C; PB: 95%; t½: 45.5 to 126 h

can develop; if this occurs, the dose may need to be increased. Failure to respond to a previously effective dose may indicate worsening asthma that requires reevaluation before increasing the dose.

ANTICHOLINERGICS

Tiotropium (Spiriva) is an anticholinergic drug used for maintenance treatment of bronchospasms associated with COPD. This drug is administered by inhalation only with the HandiHaler device (dry-powder capsule inhaler). Patients should discard any capsules that are opened and not used immediately. HandiHalers should be washed with warm water and dried. The most common adverse effects of tiotropium include dry mouth, constipation, vomiting, dyspepsia, abdominal pain, depression, insomnia, headache, joint pain, and peripheral edema. Chest pain has been reported following tiotropium administration. Prototype Drug Chart 41-1 lists the drug data related to tiotropium.

The anticholinergic drug ipratropium bromide (Atrovent) is used to treat asthmatic conditions by dilating the bronchioles. Unlike other anticholinergics, ipratropium bromide has few systemic effects. It is administered by aerosol.

Patients who use a beta-agonist inhalant should administer it 5 minutes before using ipratropium. When using the anticholinergic agent in conjunction with an inhaled glucocorticoid (steroid) or cromolyn, the ipratropium bromide should be used 5 minutes before the steroid or cromolyn. This causes the bronchioles to dilate so the steroid or cromolyn can be deposited in the bronchioles.

The combination of ipratropium bromide with albuterol sulfate (Combivent) is used to treat chronic bronchitis. The combination is more effective and has a longer duration of action than if either agent is used alone. These two agents combined increase the FEV$_1$, the index used to evaluate asthma and obstructive lung disease and the patient's response to bronchodilator therapy. Table 41-2 lists the inhalants for asthma control.

TABLE 41-2 INHALANTS FOR ASTHMA CONTROL

CATEGORIES	INHALANT AGENTS
Adrenergics	
Beta$_1$ and beta$_2$	isoproterenol (Isuprel)
Beta$_2$ and some beta$_1$	metaproterenol sulfate (Alupent, Metaprel)
Beta$_2$	albuterol (Proventil, Ventolin) pirbuterol acetate (Maxair) salmeterol (Serevent) terbutaline sulfate arformoterol tartrate (Brovana)
Anticholinergics	ipratropium bromide (Atrovent) ipratropium and albuterol (Combivent)
Antiinflammatory Drugs	
Cromolyn and nedocromil	cromolyn (NasalCrom) nedocromil
Glucocorticoids (corticosteroids)	beclomethasone (Beconase AQ) budesonide (Rhinocort Aqua) dexamethasone (Decadron) flunisolide fluticasone (Flonase) mometasone furoate (Nasonex) triamcinolone (Nasacort AQ, Kenalog IV) prednisone delayed release tablets (Rayos)

PROTOTYPE DRUG CHART 41-1

Tiotropium

Drug Class
Anticholinergic
Trade Name: Spiriva
Pregnancy Category: C

Dosage
A: Oral inhalation: 18 mcg inhalation/d at same time each day

Contraindications
Hypersensitivity, children, adolescents
Caution: Lactose hypersensitivity, Narrow-angle glaucoma, breastfeeding, older adults

Drug-Lab-Food Interactions
Drug: Increase anticholinergic effects with phenothiazines; decrease action of prokinetics (cisapride, metoclopramide, parasympathomimetics)

Pharmacokinetics
Absorption: PO: Well absorbed
Distribution: PB: 72%
Metabolism: t½: 5-6 d
Excretion: In urine as metabolites

Pharmacodynamics
Inhalation:
PO: Onset: 30 min
Peak: 1-4 h
Duration: 4-24 h

Therapeutic Effects/Uses
For maintenance treatment of bronchospasm associated with COPD
Mode of Action: Relaxes smooth muscle of bronchi; dilates bronchi by inhibiting M3 receptors

Side Effects
Insomnia, dizziness, depression, headache, nausea, vomiting, abdominal pain, constipation, urinary retention, hyperglycemia, muscle cramping in extremities, peripheral edema, blurred vision, oral ulceration

Adverse Reactions
Anaphylaxis, angioedema, dehydration, hyperglycemia
Life-threatening: Cardiac dysrhythmias, cardiac arrest, paradoxical bronchoconstriction

A, Adult; *C,* child; *h,* hour; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *y,* year.

METHYLXANTHINE (XANTHINE) DERIVATIVES

The second major group of bronchodilators used to treat asthma is the methylxanthine (xanthine) derivatives, which include aminophylline, theophylline, and caffeine. Xanthines also stimulate the central nervous system (CNS) and respiration, dilate coronary and pulmonary vessels, and cause diuresis. Because of their effect on respiration and pulmonary vessels, xanthines are used in the treatment of asthma.

Theophylline

The first theophylline preparation, aminophylline, was produced in 1936. Theophylline relaxes the smooth muscles of the bronchi, bronchioles, and pulmonary blood vessels by inhibiting the enzyme phosphodiesterase, resulting in an increase in cAMP, which promotes bronchodilation.

Theophylline has a low therapeutic index and a narrow therapeutic range (10 to 20 mcg/mL). The serum or plasma theophylline concentration level should be monitored frequently to avoid severe adverse effects. Toxicity is likely to occur when the serum level is greater than 20 mcg/mL. Certain theophylline preparations can be given with sympathomimetic (adrenergic) agents, but the dose may need to be adjusted.

Theophylline was once used as the first-line drug for treating patients with chronic asthma and other COPDs. However, theophylline use has declined sharply, because there is a potential danger of serious adverse effects (e.g., dysrhythmias, convulsions, cardiorespiratory collapse), and efficacy has not been found to be greater than beta agonists or glucocorticoids. Because of its numerous adverse reactions, drug-drug interactions, and narrow therapeutic drug range, it is prescribed mostly for maintenance therapy in patients with chronic stable asthma and other COPDs. Theophylline drugs are *not* prescribed for patients with seizure disorders or cardiac, renal, or liver disease. Patients who receive theophylline preparations need to be closely monitored for serious side effects and drug interactions.

Table 41-3 lists the theophylline preparations and their dosages, uses, and considerations.

Pharmacokinetics Theophylline is usually well absorbed after oral administration, but absorption may vary according to the specific dosage form. Theophylline is also well absorbed from oral liquids and uncoated plain tablets. Sustained-release dosage forms are slowly absorbed. Food and antacids may decrease the rate but not the extent of absorption; large volumes of fluid and high-protein meals may increase the rate of absorption. The dose size can also affect the rate of absorption: larger doses are absorbed more slowly. Theophylline can also be administered in IV fluids.

Theophylline drugs are metabolized by liver enzymes, and 90% of the drug is excreted by the kidneys. Tobacco smoking increases metabolism of theophylline drugs, thereby decreasing its half-life. The half-life is also shorter in children. With a short half-life, theophylline is readily excreted by the kidneys, so the dose may need to be increased to maintain therapeutic serum/plasma range. In nonsmokers and older adults,

TABLE 41-3 THEOPHYLLINE PREPARATIONS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
aminophylline—theophylline ethylenediamine (Elixophyllin, Theo-24)	Acute bronchospasm A: PO: IV: LD: 5-7 mg/kg infused over 20 min; *max:* 25 mg/min IV A: PO: maint: 300 mg q8h; *max:* 900 mg/d A: IV: maint: 0.5 mg/kg/hr infusion A/older adults: IV: maint: 0.375 mg/kg/hr infusion Caution: Individual titration based on serum theophylline levels. A: PO: LD 400 mg; then increase dose according to body weight; *max:* 24 mg/kg/d	IV for acute asthmatic attack. For IV use, drug must be diluted. Oral preparations are tablets or elixirs. For oral use, give with food to avoid GI distress. Side effects include restlessness, syncope, palpitations, tachycardia, hyperventilation, and cardiac dysrhythmias. Therapeutic range: 10-20 mcg/L. Pregnancy category: C; PB: 40%; t½: 6.5-10.5 h
dyphylline (Lufyllin, Dylix, Neothylline)	A: PO: 15 mg/kg q6h; *max:* 60 mg/kg/d Therapeutic serum theophylline range: 10-20 mcg/mL	Treatment of asthma, chronic bronchitis, and emphysema. One tenth as potent as theophylline. Structure similar to that of theophylline, but it does not convert to theophylline in the body. Pregnancy category: C; PB: UK; t½: 2 h

A, Adult; *C,* child; *COPD,* chronic obstructive pulmonary disease; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *LD,* loading dose; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *UK,* unknown; *y,* year; *>,* greater than; *<,* less than.

the average half-life of theophylline is 7 to 9 hours, and the dose requirements may be decreased. However, in smokers and children, the half-life is 4 to 5 hours, and the dose requirement may be increased. In premature infants, the half-life is 15 to 55 hours. In patients with heart failure (HF), cor pulmonale, COPD, or liver disease, the half-life is 12 hours. Kidney function may be decreased in older adults, so caution should be used regarding the theophylline dosage to avoid drug toxicity.

Pharmacodynamics Theophylline increases the level of cAMP, resulting in bronchodilation. The average onset of action is 30 minutes for oral preparations and 1 to 2 hours for sustained-release capsules. The duration of action is 8 to 24 hours for the sustained-release form and approximately 6 hours for other oral and IV theophylline preparations.

Side Effects and Adverse Reactions

Side effects and adverse reactions to theophylline include anorexia, nausea and vomiting, gastric pain caused by increased gastric acid secretion, intestinal bleeding, nervousness, dizziness, headache, irritability, cardiac dysrhythmias, tachycardia, palpitations, marked hypotension, hyperreflexia, and seizures. Adverse CNS reactions (e.g., headaches, irritability, restlessness, nervousness, insomnia, dizziness, seizures) are often more severe in children than in adults. To decrease the potential for side effects, patients should not take other xanthines while taking theophylline.

Theophylline toxicity is most likely to occur when serum concentrations exceed 20 mcg/mL. Theophylline can cause hyperglycemia, decreased clotting time, and, rarely, increased white blood cell count (leukocytosis). Because of the diuretic effect of xanthines, including theophylline, patients should avoid caffeinated products (e.g., coffee, tea, cola, chocolate) and increase fluid intake.

Rapid IV administration of aminophylline (a theophylline product) can cause dizziness, flushing, hypotension, severe bradycardia, and palpitations. To avoid severe adverse effects, IV theophylline preparations *must be administered slowly* via an infusion pump.

Drug Interactions

Beta blockers, cimetidine (Tagamet), propranolol (Inderal), and erythromycin (E-Mycin) decrease the liver metabolism rate and increase the half-life and effects of theophylline; barbiturates and carbamazepine (Tegretol) decrease its effects. In both situations, the theophylline dosage would need adjustment. Theophylline increases the risk of digitalis toxicity and decreases the effects of lithium. Phenytoin (Dilantin) decreases theophylline levels. If theophylline and a beta-adrenergic agonist are given together, a synergistic effect can occur and result in cardiac dysrhythmias.

LEUKOTRIENE RECEPTOR ANTAGONISTS AND SYNTHESIS INHIBITORS

Leukotriene (LT) is a chemical mediator that can cause inflammatory changes in the lung. The cysteinyl leukotrienes promote an increase in eosinophil migration, mucus production, and airway wall edema, which result in bronchoconstriction. LT receptor antagonists and LT synthesis inhibitors, called *leukotriene modifiers,* are effective in reducing the inflammatory symptoms of asthma triggered by allergic and environmental stimuli. These drug groups are not recommended for treatment of acute asthmatic attack. They are used for exercise-induced asthma. Three leukotriene modifiers—zafirlukast (Accolate), zileuton (Zyflo CR), and montelukast sodium (Singulair)—are available in the United States. These drugs are listed in Table 41-4.

TABLE 41-4 ANTIINFLAMMATORY DRUGS FOR CHRONIC OBSTRUCTIVE PULMONARY DISEASE

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Leukotriene Modifiers (Do Not Administer for Acute Asthmatic Attack)		
Leukotriene Receptor Antagonists		
zafirlukast (Accolate)	A: PO: 20 mg b.i.d. 1 h before or 2 h after meals; *max:* 40 mg/d C: >5 y: PO: 10 mg b.i.d.; *max:* 20 mg/d	For prophylaxis and maintenance therapy for chronic asthma. Reduces inflammation within bronchial tubes and airways. Pregnancy category: B; PB: 99%; t½: 10 h
montelukast (Singulair)	See Prototype Drug Chart 41-2.	
Leukotriene Synthesis Inhibitors		
zileuton (Zyflo CR)	ER: A: PO: 1200 mg b.i.d. within 1 h after morning and evening meal	For prophylaxis and maintenance therapy for chronic asthma. Reduces inflammation in airways and decreases bronchoconstriction. Hepatotoxicity may result; closely monitor liver enzymes. Pregnancy category: C; PB: 93%; t½: 2.5 h
Glucocorticoids (Corticosteroids)		
Intranasal Spray (see Chapter 40)		
Phosphodiesterase-4 Inhibitor		
roflumilast (Daliresp)	A: PO: 500 mcg/d	For treatment of exacerbations in severe COPD. Common adverse effects include diarrhea and weight loss. Contraindicated in moderate to severe liver impairment. Pregnancy Category: C; PB: 99%; t½: 17 h
beclomethasone (Beconase AQ, QNASL)		
budesonide (Pulmicort, Rhinocort Aqua)		
flunisolide		
fluticasone (Flonase)		
mometasone furoate (Nasonex)		
triamcinolone (Nasacort AQ)		
Aerosol Inhalation (see Chapter 51)		
beclomethasone (Qvar)		
flunisolide (Aerospan)		
budesonide (Pulmicort Flexhaler)		
fluticasone (Flovent Diskus)		
Oral and Intravenous Administration (see Chapter 51)		
betamethasone dipropinate		
cortisone acetate		
dexamethasone (Decadron)		
fludrocortisone acetate		
hydrocortisone (Cortef, Aquacort)		
methylprednisolone (Medrol, Solu-Medrol, Depo-Medrol)		
prednisolone (Flo-Pred, Orapred)		
prednisone		
triamcinolone (Kenalog IV)		
Combination Drug: Glucocorticoid and Beta$_2$ Agonist		
fluticasone propionate and salmeterol (Advair Diskus, Advair HFA)	A/C: >12 y: Inhal DPI Diskus: 1 puff q12h	For asthma; not to treat acute asthmatic attacks. If insufficient response, fluticasone dose may be increased. Pregnancy category: C; PB: 91%-98%; t½: 3-8 h
fluticasone propionate and vilanterol (Breo Ellipta)	A: Inhal: 1 inhalation qd	For long-term maintenance of COPD, including bronchitis or emphysema. Pregnancy category: C; PB: 93.7%-99.6%; t½: 21.3-24 h

Continued

TABLE 41-4 ANTIINFLAMMATORY DRUGS FOR CHRONIC OBSTRUCTIVE PULMONARY DISEASE—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Cromolyn and Nedocromil (Do Not Use for Acute Asthmatic Attack)		
cromolyn sodium (Gastrocrom)	A/C: >6 y: Inhal MDI: 1-2 puffs 10-15 min before exercise	For chronic asthma and prophylactic use. Suppresses inflammation in bronchial tubes; does not have bronchodilating effects. Prevents release of histamine. Pregnancy category: B; PB: UK; t½: 80 min
nedocromil sodium	A/C: >6 y: Inhal MDI: 2 puffs q.i.d.; may decrease to b.i.d./t.i.d.	For maintenance therapy in mild to moderate asthma. Has antiinflammatory effect. Suppresses release of histamine. Pregnancy category: B; PB: UK; t½: 2.3 h

A, Adult; *b.i.d.,* twice a day; *C,* child; *DPI,* dry-powder inhaler; *ER,* extended-release; *h,* hour; *inhal,* inhalation; *MDI,* metered-dose inhaler; *min,* minute; *PB,* protein binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *y,* year; *>,* greater than.

Nursing Process
Patient-Centered Collaborative Care

Bronchodilators

Assessment
- Obtain a medical and drug history; report probable drug-drug interactions.
- Note baseline vital signs and pulse oximetry for abnormalities and future comparisons.
- Assess for wheezing, decreased breath sounds, cough, and sputum production.
- Assess sensorium for confusion and restlessness caused by hypoxia and hypercapnia.
- Determine hydration; diuresis may result in dehydration in children and older adults.
- Assess serum theophylline levels. Toxicity occurs at a higher frequency with levels greater than 20 mcg/mL.

Nursing Diagnoses
- Ineffective breathing pattern related to fatigue
- Ineffective airway clearance related to retained secretions in the bronchi
- Impaired gas exchange related to ineffective airway clearance
- Noncompliance with drug therapy related to inadequate financial resources
- Activity intolerance related to fatigue and an imbalance between oxygen supply and demand

Planning
- Patient will be free from wheezing, and lung fields will be clear within 2 to 5 days.
- Patient will self-administer oral drugs and inhaler as prescribed.

Nursing Interventions
- Monitor vital signs. Blood pressure and heart rate can increase greatly. Check for cardiac dysrhythmias.
- Provide adequate hydration. Fluids aid in loosening secretions.
- Monitor drug therapy.
- Observe for side effects.
- Administer medication after meals to decrease gastrointestinal distress.
- Administer medication at regular intervals around the clock to have a sustained therapeutic level.
- Do *not* crush enteric-coated or sustained-released (SR) tablets or capsules.
- Check serum theophylline levels (normal level is 10 to 20 mcg/mL).

Patient Teaching
General
- Teach patient to monitor pulse rate.
- Encourage patient to monitor amount of medication remaining in the canister.
- Advise patient not to take over-the-counter (OTC) preparations without first checking with health care provider. Some OTC products may have an additive effect.
- Encourage patient contemplating pregnancy to seek medical advice before taking a theophylline preparation.
- Advise patient to avoid smoking. Avoid marked sudden changes in smoking amounts, which could affect theophylline blood levels. Smoking increases drug elimination, which may require an increased drug dose.
- Discuss ways to alleviate anxiety, such as relaxation techniques and music.
- Advise patient having asthmatic attacks to wear an ID bracelet or MedicAlert tag.
- Inform patient that certain herbal products may interact with theophylline (Herbal Alert 41-1).
- Advise patient to notify health care provider of aggressive or altered behavior and suicidal thoughts.

Self-Administration

- Teach patient to correctly use inhaler or nebulizer. Caution against overuse, because side effects and tolerance may result.
- Teach patient to monitor pulse rate and report to health care provider any irregularities in comparison with baseline.

Diet

- Advise patient that high-protein, low-carbohydrate diet increases theophylline elimination. Conversely, low-protein, high-carbohydrate diet prolongs half-life; dosage may need adjustment.

Correct Use of Metered-Dose Inhaler to Deliver Beta$_2$ Agonist

- Insert medication canister into plastic mouthpiece.
- Shake inhaler well *before* using. Remove cap from mouthpiece.
- Breathe *out* through the mouth. Open mouth wide, and hold mouthpiece 1 to 2 inches from mouth, or place inhaler mouthpiece in mouth. A spacer may be used. Discuss technique with health care provider.
- Open mouth, take a *slow deep* breath through the mouth, and at the same time push top of medication canister once.
- Hold breath for a few seconds; exhale slowly through pursed lips.
- Wait 2 minutes if a second dose is required, and then repeat the procedure by first shaking the inhaler with the mouthpiece cap in place.
- Do a "test spray" before administering the metered dose of a new inhaler or when the inhaler has not been used recently.
- Self-administer a bronchodilator first when taken at the same time as a steroid, and then *wait 5 minutes* for optimal bronchodilator effect before using the steroid.

Cultural Considerations

- Respect cultural beliefs and practices concerning alternative ways to treat asthma or other chronic obstructive pulmonary disease, and incorporate alternative treatments into patient care if they are harmless. If traditional practices/medicines are unsafe, explain in terms that can be understood.
- If patient from different cultural background does not comply with drug regimen, consult health care provider of similar background, and provide a written plan in language patient speaks and reads most easily.

Evaluation

- Evaluate effectiveness of bronchodilator. Patient is breathing without wheezing and free from side effects of the drug.
- Determine serum theophylline levels to assure therapeutic range.

HERBAL ALERT 41-1

Lower Respiratory Disorders

- Ephedra may increase the effect of the theophylline group and may cause theophylline toxicity.
- St. John's wort may decrease montelukast concentration.

Zafirlukast (Accolate) was the first drug in the class of leukotriene modifiers. It acts as an LT receptor antagonist, reducing the inflammatory process and decreasing bronchoconstriction. It is administered orally and absorbed rapidly. It has a moderate to moderately long half-life and is given twice a day. Zileuton (Zyflo CR) is an LT synthesis inhibitor. It decreases the inflammatory process and bronchoconstriction. Zileuton has a short half-life of 2.5 hours. Montelukast (Singulair) is a newer LT receptor antagonist (Prototype Drug Chart 41-2). It has a short half-life of 2.7 to 5.5 hours and is considered safe for use in children 6 years of age and older.

Nursing Process

Patient-Centered Collaborative Care

Leukotriene Receptor Antagonists

Assessment

- Obtain a medical, drug, and herbal history; report probable drug-drug or drug-herb interactions.
- Note baseline vital signs for identifying abnormalities and for future comparisons.
- Assess for wheezing, decreased breath sounds, cough, and sputum production.
- Assess sensorium for confusion and restlessness caused by hypoxia and hypercapnia.
- Assess for a history of phenylketonuria when montelukast is prescribed, because children's chewable tablets contain phenylalanine.
- Determine hydration; diuresis may result in dehydration in children and older adults.

Nursing Diagnoses

- Ineffective airway clearance related to retained secretions in bronchi
- Activity intolerance related to imbalance between oxygen supply and demand
- Deficient knowledge of OTC drug interaction related to lack of exposure to information

Planning

- Patient will be free from wheezing, or wheezing has significantly improved.
- Patient's lung fields will be clear within 2 to 5 days.
- Patient will take medications as prescribed.

PROTOTYPE DRUG CHART 41-2

Montelukast

Drug Class
Bronchodilator: leukotriene receptor antagonist
Trade Name: Singulair
Pregnancy Category: B

Dosage
A: PO: 10 mg/d at least 2 h before exercise
C: 6-15 y: PO: 5 mg/d at least 2 h before exercise

Contraindications
Hypersensitivity, severe asthmatic attack, status asthmaticus or acute bronchospasm
Caution: Severe liver disease, suicidal ideation, breastfeeding, corticosteroid withdrawal

Drug-Lab-Food Interactions
Lab: Abnormal liver function tests (ALT, AST)

Pharmacokinetics
Absorption: Well absorbed
Distribution: PB: 99%
Metabolism: t½: 2.7-5.5 h
Elimination: Feces, bile

Pharmacodynamics
PO: Onset: UK
Peak: 3-4 h
Duration: 24 h

Therapeutic Effects/Uses
For prevention of bronchospasm and maintenance treatment of asthma
Mode of Action: Binds with leukotriene receptors to inhibit smooth muscle contraction and bronchoconstriction

Side Effects
Fever, headache, drowsiness, dizziness, fatigue, restlessness, insomnia, confusion, depression, nasal congestion, cough, sore throat, dental pain, influenza, dyspepsia, nausea, vomiting, abdominal pain, weight loss, rash

Adverse Reactions
Angioedema, bleeding, vasculitis, seizures, edema
Life-threatening: anaphylaxis, suicidal ideation, Stevens-Johnson syndrome

A, Adult; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *C,* child; *h,* hour; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *y,* year.

Nursing Interventions

- Monitor respirations for rate, depth, rhythm, and type.
- Monitor lung sounds for rhonchi, wheezing, or rales.
- Observe lips and fingernails for cyanosis.
- Monitor drug therapy for effectiveness.
- Observe for side effects.
- Provide adequate hydration; fluids aid in loosening secretions.
- Monitor liver function tests; AST and ALT may be elevated with zafirlukast and montelukast.
- Provide pulmonary therapy by chest clapping and postural drainage, as appropriate.

Patient Teaching

General

- Advise patient that if allergic reaction occurs (i.e., rash, urticaria), drug should be discontinued and health care provider should be notified.
- Monitor periodic liver function tests.
- Direct patient not to take St. John's wort without first checking with health care provider, because this herb may decrease montelukast concentration.
- Warn patient that black or green tea and guarana with montelukast and zafirlukast may cause increased stimulation.
- Encourage patient to stop smoking.
- Discuss ways to alleviate anxiety (relaxation techniques, music).
- Advise patient having frequent or severe asthmatic attacks to wear an ID bracelet or MedicAlert tag.
- Encourage patient contemplating pregnancy to seek medical advice before taking montelukast.
- Caution patient or significant other not to open oral granule packets until ready for use. After opening packet, dose must be administered within 15 minutes. If mixed with baby formula or approved food (applesauce, carrots, rice, or ice cream), do not store for future use.
- Advise patient with known aspirin sensitivity to avoid a bronchoconstrictor response by avoiding aspirin and NSAIDs while taking montelukast.

Self-Administration

- Teach patient not to use montelukast for reversal of an acute asthmatic attack, because it is only recommended for prevention of acute attacks and treatment of chronic asthma.
- Advise patient to continue to use the usual regimen of inhaled prophylaxis and short-acting rescue medication for exercise-induced bronchospasm.

- Encourage patient to inform health care provider if short-acting inhaled bronchodilators are needed more often than usual with montelukast.
- Tell patient to comply with medication regimen even during symptom-free periods.
- Advise patient (especially children) that chewable tablets are to be chewed thoroughly because swallowing whole may alter absorption.

Diet

- Tell patient to take leukotriene receptor antagonists in the evening for maximum effectiveness.

Cultural Considerations

- Use both hands to show respect when offering a prescription, instructions, or pamphlets to Asians and Pacific Islanders.

Evaluation

- Evaluate the effectiveness of the bronchodilators. Patient is breathing without wheezing and without side effects of the drug.
- Evaluate tolerance to activity.

This category of drugs is the newest group used to control asthma. Again, LT receptor antagonists and synthesis inhibitors should *not* be used during an acute asthmatic attack. They are only for prophylactic and maintenance drug therapy for chronic asthma.

GLUCOCORTICOIDS (STEROIDS)

Glucocorticoids, members of the corticosteroid family, are used to treat respiratory disorders, particularly asthma. These drugs have an antiinflammatory action and are indicated if asthma is unresponsive to bronchodilator therapy or if the patient has an asthmatic attack while on maximum doses of theophylline or an adrenergic drug. It is thought that glucocorticoids have a synergistic effect when given with a beta$_2$ agonist.

Glucocorticoids can be given using the following methods:

- *MDI inhaler:* beclomethasone (Beconase AQ, QNASL, Qvar)
- *Tablet:* dexamethasone (Decadron), prednisone, prednisolone, and methylprednisolone
- *Intravenous:* dexamethasone (Decadron), hydrocortisone

Inhaled glucocorticoids are not helpful in treating a severe asthmatic attack, because it may take 1 to 4 weeks for an inhaled steroid to reach its full effect. When maintained on inhaled glucocorticoids, asthmatic patients demonstrate an improvement in symptoms and a decrease in asthmatic attacks. Inhaled glucocorticoids are more effective for controlling symptoms of asthma than beta$_2$ agonists, particularly in the reduction of bronchial hyperresponsiveness. The use of an oral inhaler minimizes the risk for adrenal suppression associated with oral systemic glucocorticoid therapy. Inhaled glucocorticoids are preferred over oral preparations unless they fail to control the asthma.

Patients with acute asthma exacerbations are usually given systemic glucocorticoids (i.e., IV) for rapid effectiveness in large doses (20 to 40 mg prednisone for 5 days; 1 to 2 mg/kg/day for children for 3 to 5 days). An additional week with a reduced dose may be needed. With a single dose or short-term use, glucocorticoids may be discontinued abruptly after symptoms are controlled. Suppression of adrenal function does not usually occur within 1 to 2 weeks.

When severe asthma requires prolonged glucocorticoid therapy, weaning or tapering of the dose may be necessary to prevent an exacerbation of asthma symptoms and suppression of adrenal function. Previously, alternate-day therapy (ADT) with oral prednisone was used in some asthmatic patients. Currently, inhaled glucocorticoids are thought to be preferable in the treatment of most patients with asthma. Glucocorticoid preparations are discussed in detail in Chapter 51.

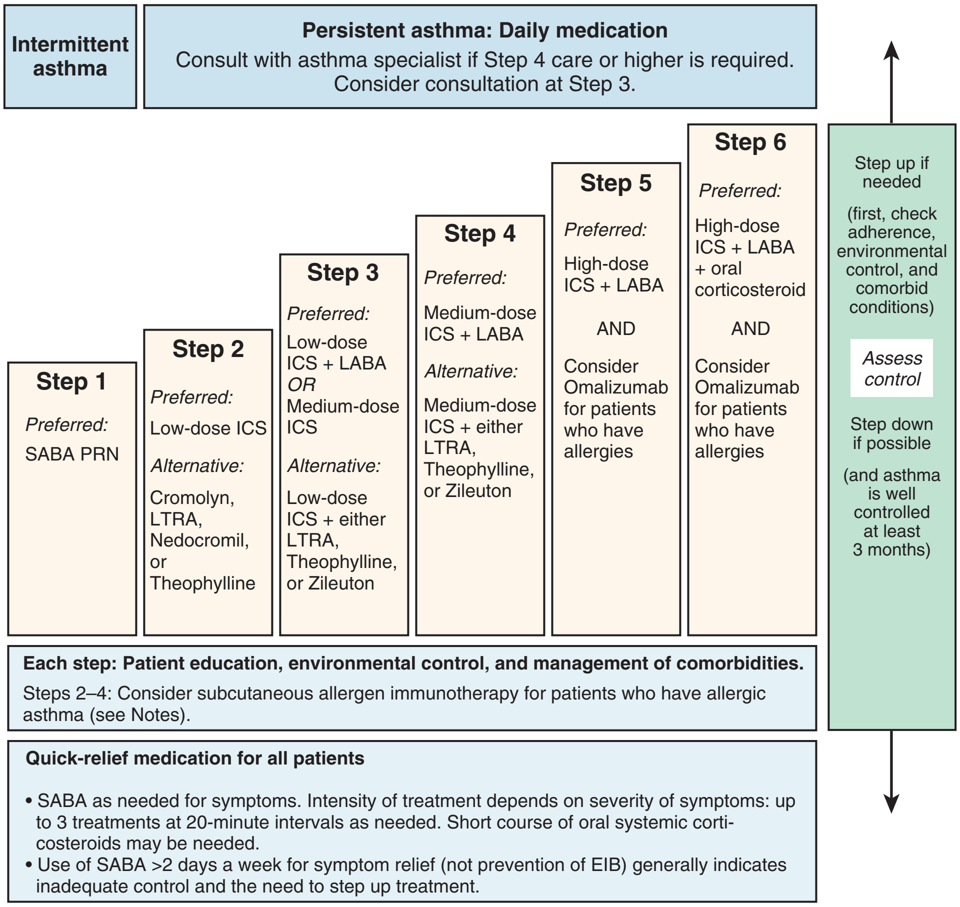
Glucocorticoids can irritate the gastric mucosa and should be taken with food to avoid ulceration. A combination drug containing the glucocorticoid fluticasone propionate 100 mcg and salmeterol 50 mcg (Advair Diskus 100/50) is effective in controlling asthma symptoms. Advair is used every day, but requires only one inhalation in the morning and one at night. This drug does not replace fast-acting inhalers for sudden symptoms. The purpose of Advair is to alleviate airway constriction and inflammation.

Side Effects and Adverse Reactions

Side effects associated with orally inhaled glucocorticoids are generally local (e.g., throat irritation, hoarseness, dry mouth, coughing) rather than systemic. Oral, laryngeal, and pharyngeal fungal infections have occurred but can be reversed with discontinuation and antifungal treatment. *Candida albicans* oropharyngeal infections may be prevented by using a spacer with the inhaler to reduce drug deposits in the oral cavity, rinsing the mouth and throat with water after each dose, and washing the apparatus (cap and plastic nose or mouthpiece) daily with warm water.

Oral and injectable glucocorticoids have many side effects when used long-term, but short-term use usually causes no significant side effects. Most adverse reactions are seen within 2 weeks of glucocorticoid therapy and are usually reversible. Side effects that may occur include headache, euphoria, confusion, sweating, hyperglycemia, insomnia, nausea, vomiting, weakness, and menstrual irregularities. Adverse effects may include depression, peptic ulcer, loss of bone density and development of osteoporosis, and psychosis.

When oral and IV steroids are used for prolonged periods, electrolyte imbalance, fluid retention (puffy eyelids, edema in the lower extremities, moon face, weight gain), hypertension, thinning of the skin, purpura, abnormal subcutaneous (fat) distribution, hyperglycemia, and impaired immune response are likely to occur.



Intermittent asthma
Persistent asthma: Daily medication
Consult with asthma specialist if Step 4 care or higher is required.
Consider consultation at Step 3.
Step 1
Preferred:
SABA PRN
Step 2
Preferred:
Low-dose ICS
Alternative:
Cromolyn, LTRA, Nedocromil, or Theophylline
Step 3
Preferred:
Low-dose ICS + LABA
OR
Medium-dose ICS
Alternative:
Low-dose ICS + either LTRA, Theophylline, or Zileuton
Step 4
Preferred:
Medium-dose ICS + LABA
Alternative:
Medium-dose ICS + either LTRA, Theophylline, or Zileuton
Step 5
Preferred:
High-dose ICS + LABA
AND
Consider Omalizumab for patients who have allergies
Step 6
Preferred:
High-dose ICS + LABA + oral corticosteroid
AND
Consider Omalizumab for patients who have allergies
Step up if needed
(first, check adherence, environmental control, and comorbid conditions)
Assess control
Step down if possible
(and asthma is well controlled at least 3 months)

Each step: Patient education, environmental control, and management of comorbidities.

Steps 2–4: Consider subcutaneous allergen immunotherapy for patients who have allergic asthma (see Notes).

Quick-relief medication for all patients

- SABA as needed for symptoms. Intensity of treatment depends on severity of symptoms: up to 3 treatments at 20-minute intervals as needed. Short course of oral systemic corticosteroids may be needed.
- Use of SABA >2 days a week for symptom relief (not prevention of EIB) generally indicates inadequate control and the need to step up treatment.

Key: **Alphabetical order is used when more than one treatment option is listed within either preferred or alternative therapy.** ICS, inhaled corticosteroid; LABA, long-acting inhaled beta$_2$-agonist; LTRA, leukotriene receptor antagonist; SABA, inhaled short-acting beta$_2$-agonist

Notes:

- The stepwise approach is meant to assist, not replace, the clinical decision making required to meet individual patient needs.
- If alternative treatment is used and response is inadequate, discontinue it and use the preferred treatment before stepping up.
- Zileuton is a less desirable alternative due to limited studies as adjunctive therapy and the need to monitor liver function. Theophylline requires monitoring of serum concentration levels.
- In Step 6, before oral corticosteroids are introduced, a trial of high-dose ICS + LABA + either LTRA, Theophylline, or Zileuton may be considered, although this approach has not been studied in clinical trials.
- Step 1, 2, and 3 preferred therapies are based on Evidence A; Step 3 alternative therapy is based on Evidence A for LTRA, Evidence B for Theophylline, and Evidence D for Zileuton. Step 4 preferred therapy is based on Evidence B, and alternative therapy is based on Evidence B for LTRA and Theophylline and Evidence D Zileuton. Step 5 preferred therapy is based on Evidence B. Step 6 preferred therapy is based on (EPR–2 1997) and Evidence B for Omalizumab.
- Immunotherapy for Steps 2–4 is based on Evidence B for house-dust mites, animal danders, and pollens; evidence is weak or lacking for molds and cockroaches. Evidence is strongest for immunotherapy with single allergens. The role of allergy in asthma is greater in children than in adults.
- Clinicians who administer immunotherapy or Omalizumab should be prepared and equipped to identify and treat anaphylaxis that may occur.

FIGURE 41–3 Stepwise approach for managing asthma in patients 12 years and older. (From the National Asthma Education and Prevention Program Expert Panel Report 3: *Guidelines for the diagnosis and management of asthma.* Washington, DC, National Heart, Lung, and Blood Institute, U.S. Department of Health and Human Services. Accessed November 14, 2012, at *www.nhlbi.nih.gov/guidelines/asthma/asthgdln.htm*.)

CROMOLYN AND NEDOCROMIL

Cromolyn sodium (NasalCrom) is used for prophylactic treatment of bronchial asthma and must be taken daily. It is not used for acute asthmatic attacks. Cromolyn does not have bronchodilator properties, but instead acts by inhibiting histamine release to prevent an asthma reaction. Its most common side effects are cough and a bad taste. These effects can be decreased by drinking water before and after using the drug.

Cromolyn is administered by inhalation. It can be used with beta adrenergics and xanthine derivatives. Rebound bronchospasm is a serious side effect of cromolyn. The drug should not be discontinued abruptly, because a rebound asthmatic attack can result.

Action and uses of nedocromil sodium are similar to those of cromolyn sodium. It has an antiinflammatory effect and suppresses the release of histamine, leukotrienes, and other mediators from the mast cells. Like cromolyn it should not be used during an acute asthmatic attack, but instead to prevent bronchospasm and acute asthmatic attack. Inhalation may cause an unpleasant taste. Nedocromil is believed to be more effective than cromolyn.

Table 41-4 lists antiinflammatory drugs for COPD, including LT receptor antagonists, LT synthesis inhibitors, glucocorticoids (intranasal spray, aerosol inhalation, combination drug, and oral, intramuscular, and intravenous form), cromolyn sodium, and nedocromil sodium.

DRUG THERAPY FOR ASTHMA ACCORDING TO SEVERITY

Chronic asthma may be controlled through a long-term drug treatment program and by a quick-relief program during an acute phase. Figure 41-3 presents a list of steps for controlling and treating chronic asthma according to severity. This treatment regimen was developed in 1997 and updated in 2007 by the National Asthma Education and Prevention Program of the National Heart, Lung, and Blood Institute in Bethesda, Maryland. The long-term drug treatment program may vary according to the symptoms of the asthma and its severity. The quick-relief drug therapy is the same for all classes of asthma.

DRUG THERAPY FOR ASTHMA ACCORDING TO AGE

Young Children

Cromolyn and nedocromil are drugs used to treat the inflammatory effects of asthma in children. Oral glucocorticoids may be prescribed for the young child to control a moderate to severe asthmatic state. An inhalation dose of a glucocorticoid should be about 1 to 2 inhalations 3 to 4 times a day or 40 to 80 mcg twice a day. If the condition is severe, selected young children may be ordered an oral beta$_2$-adrenergic agonist.

Older Adults

Drug selection and dosage need to be considered for the older adult with an asthmatic condition. Beta$_2$-adrenergic agonists and methylxanthines (e.g., theophylline) can cause tachycardia, nervousness, and tremors in older adults, especially those with cardiac conditions. Frequent use of glucocorticoids can increase the risk of the patient developing cataracts, osteoporosis, and diabetes mellitus. If a theophylline drug is ordered, dosages of glucocorticoids are normally decreased.

MUCOLYTICS

Mucolytics act like detergents to liquefy and loosen thick mucous secretions so they can be expectorated. Acetylcysteine (Mucomyst) is administered by nebulization. *The drug should not be mixed with other drugs.* When patients with asthma or hyperactive airway disease produce increased secretions that obstruct bronchial airways, acetylcysteine may be administered as an adjunct to a bronchodilator (not mixed together). The bronchodilator should be given 5 minutes before the mucolytic. Side effects include nausea and vomiting, stomatitis (oral ulcers), and "runny nose."

Acetylcysteine (Mucomyst) can be used as an antidote for acetaminophen (Tylenol) overdose if given within 12 to 24 hours after the overdose ingestion. It can be given orally, diluted in juice or soft drinks.

Dornase alfa (Pulmozyme) is an enzyme that digests deoxyribonucleic acid (DNA) in thick sputum secretions of patients with cystic fibrosis (CF). This agent helps reduce respiratory infections and improves pulmonary function. Improvement usually occurs in 3 to 7 days with its use. Side effects include chest pain, sore throat, laryngitis, and hoarseness.

ANTIMICROBIALS

Antibiotics are used only if a bacterial infection results from retained mucus secretions. Trimethoprim-sulfamethoxazole is effective for the treatment of mild to moderate acute exacerbations of chronic bronchitis (AECB) from infectious causes.

CRITICAL THINKING CASE STUDY

MA, a 55-year-old patient, was recently diagnosed with bronchial asthma. Her mother and three brothers also have asthma. In the past year, MA has had three asthmatic attacks that were treated with prednisone and albuterol (Proventil) inhaler. At an office visit today, prednisone is prescribed for 4 weeks, and the order is written as follows: day 1—1 tablet 4 times a day; day 2—1 tablet 3 times a day; day 3—1 tablet 2 times a day; day 4—1 tablet in the morning; day 5—one-half tablet in the morning.

1. Explain the purpose for the use of prednisone during an asthmatic attack. Explain why the dosage is decreased (tapered) over a period of 5 days.
2. Can cromolyn sodium (NasalCrom) be substituted for prednisone during an asthmatic attack? Explain your answer.
3. MA is prescribed albuterol (Proventil, Ventolin). What effect does albuterol have on controlling asthma?
4. For each drug dose, MA is to take two puffs of albuterol administered by the inhaler. What instructions should she be given concerning use of the inhaler?

To minimize the frequency of MA's asthmatic attacks, the health care provider prescribes theophylline (Elixophyllin) 200 mg twice a day. The albuterol inhalation is to be taken as needed. Nursing interventions include patient history of asthmatic attacks and physical assessment.

5. When taking the patient's history, what should the nurse include concerning asthmatic attacks? What physical assessment would suggest an asthmatic attack?
6. What type of drug is Elixophyllin? Why should the nurse ask MA if she smokes?
7. What are the side effects, adverse reactions, and drug interactions related to Elixophyllin?
8. What nonpharmacologic measures can the nurse suggest that may decrease the frequency of asthmatic attacks?
9. Which are appropriate rescue medications used for acute asthmatic attacks? Which drugs are used as preventive medications?

NCLEX STUDY QUESTIONS

1. An Advair Diskus, fluticasone propionate (Flonase) and salmeterol (Serevent) 100 mcg/50 mcg, is ordered for a patient with COPD. What does the nurse know about this medication? (Select all that apply.)
   - a. It can be used to treat an acute attack.
   - b. It is delivered as a dry powdered inhaler.
   - c. It contains a beta$_1$ agonist and Cromolyn.
   - d. It is taken as one puff two times a day.
   - e. It promotes bronchodilation.
2. A patient with COPD has an acute bronchospasm. The nurse anticipates that the health care provider will prescribe which medication?
   - a. zafirlukast (Accolate)
   - b. epinephrine (Adrenalin)
   - c. dexamethasone (Decadron)
   - d. oxtriphylline-theophyllinate
3. A patient is prescribed aminophylline–theophylline. For what adverse effect should the nurse monitor the patient?
   - a. Drowsiness
   - b. Hypoglycemia
   - c. Increased heart rate
   - d. Decreased white blood cell count
4. A patient is receiving IV aminophylline. The nurse checks the patient's lab values. The serum theophylline level is 32 mcg/mL. What action should the nurse take?
   - a. Assess the patient's breath sounds for improvement.
   - b. Increase the dosage per sliding scale directions.
   - c. Notify the health care provider of the level.
   - d. Have the laboratory collect another sample to verify the results.
5. A patient with COPD is taking a leukotriene antagonist, montelukast (Singulair). The nurse is aware that this medication is given for which purpose?
   - a. Maintenance treatment of asthma
   - b. Treatment of acute asthmatic attack
   - c. Reversing bronchospasm associated with COPD
   - d. Treatment of inflammation in chronic bronchitis

Answers: 1, b, d, e; 2, b; 3, c; 4, c; 5, a.

UNIT XIV

Cardiovascular Agents

The cardiovascular system includes the heart, blood vessels (arteries and veins), and blood flow. Blood that is abundant in oxygen (O_2), nutrients, and hormones moves through vessels called *arteries,* which narrow to arterioles and then capillaries. Capillaries transport nourished blood to body cells and absorb waste products, such as carbon dioxide (CO_2), urea, creatinine, and ammonia. The deoxygenated blood returns to the circulation by small venules and larger veins to be eliminated by the lungs and kidneys with other waste products (Figure XIV-1).

The heart's pumping action serves as the energy source that circulates blood to body cells. Blockage of vessels can inhibit blood flow.

HEART

The heart is composed of four chambers including the right and left atria and the right and left ventricles (Figure XIV-2). The right atrium receives deoxygenated blood from the circulation, and the right ventricle pumps blood through the pulmonary artery to the lungs for gas exchange (carbon dioxide for oxygen). The left atrium receives oxygenated blood, and the left ventricle pumps the blood into the aorta for systemic circulation.

The heart muscle, called the *myocardium,* surrounds the ventricles and atria. The ventricles have thick walls (especially the left ventricle) to produce the muscular force needed to pump blood to the pulmonary and systemic circulations. The atria have thin walls, have less pumping action, and receive blood from the circulation and lungs.

The heart has a fibrous covering called the *pericardium*, which protects it from injury and infection. The *endocardium* is a three-layered membrane that lines the inner part of the heart chambers. Four valves—two atrioventricular (tricuspid and mitral) and two semilunar (pulmonic and aortic)—control blood flow between the atria and ventricles and between the ventricles and the pulmonary artery and the aorta. There are two main coronary arteries. The right coronary artery divides into branches that supply blood to the right atrium and both ventricles of the heart. The left coronary artery divides near its origin to form the left circumflex artery and the anterior descending artery, which supply blood to the left atrium and both ventricles of the heart. Blockage to one of these arteries can result in a myocardial infarction (MI), or heart attack.

CONDUCTION OF ELECTRICAL IMPULSES

The myocardium is capable of generating and conducting its own electrical impulses. The cardiac impulse normally originates in the *sinoatrial (SA)* node located in the posterior wall of the right atrium. The SA node is frequently called the *pacemaker*, because it regulates the heartbeat (firing of cardiac impulses), which is approximately 60 to 80 beats/min in the normal adult. The *atrioventricular (AV) node*, located in the posterior right side of the interatrial septum, has a continuous tract of fibers called the *bundle of His*, or the AV bundle. The AV node is called the

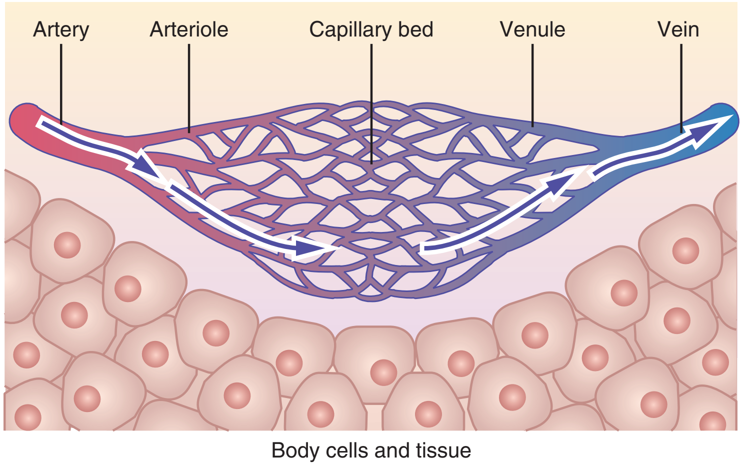

FIGURE XIV–1 Basic structures of the vascular system.

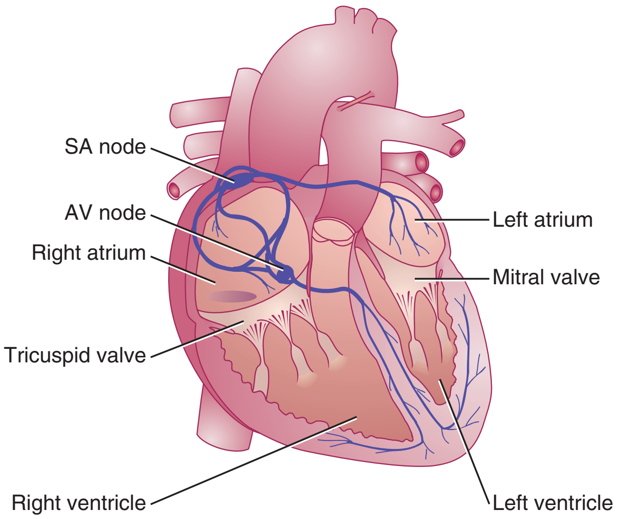

FIGURE XIV–2 Anatomy of the heart. *AV node,* Atrioventricular node; *SA node,* sinoatrial node.

pacemaker, having an adult rate of 40 to 60 beats/min. If the SA node fails, the AV node takes over, thus causing a slower heart rate. The AV node sends impulses to the ventricles. These two conducting systems (SA node and AV node) can act independently of each other. The ventricle can contract independently 30 to 40 times per minute.

Drugs that affect cardiac contraction include calcium, digitalis preparations, quinidine, and its related preparations. The autonomic nervous system (ANS) and drugs that stimulate or inhibit it influence heart contractions. The sympathetic nervous system and drugs that stimulate it *increase* heart rate; the parasympathetic nervous system and drugs that stimulate it *decrease* heart rate.

REGULATION OF HEART RATE AND BLOOD FLOW

The heart beats approximately 60 to 80 times per minute in an adult, pumping blood into the systemic circulation. As blood travels, resistance to blood flow develops and arterial pressure increases. The average systemic arterial pressure, known as *blood pressure*, is 120/80 mm Hg. Arterial blood pressure is determined by peripheral resistance and *cardiac output*. Cardiac output is the volume of blood expelled from the heart in 1 minute, which is calculated by multiplying the heart rate by the stroke volume. The average cardiac output is 4 to 8 L/min. *Stroke volume*, the amount of blood ejected from the left ventricle with each heartbeat, is approximately 70 mL/beat.

Three factors—preload, contractility, and afterload—determine the stroke volume (Figure XIV-3). *Preload* refers to the blood flow force that stretches the ventricle at the end of diastole. However, an increase in preload can increase stroke volume, and a decrease in preload can decrease stroke volume. *Contractility* is the force of ventricular contraction, and afterload is the resistance to ventricular ejection of blood, which is caused by opposing pressures in the aorta and systemic circulation. If afterload increases, stroke volume will decrease, and if afterload decreases, stroke volume will increase.

Specific drugs can increase or decrease preload and afterload, affecting both stroke volume and cardiac output. Most vasodilators decrease preload and afterload, thus decreasing arterial pressure and cardiac output.

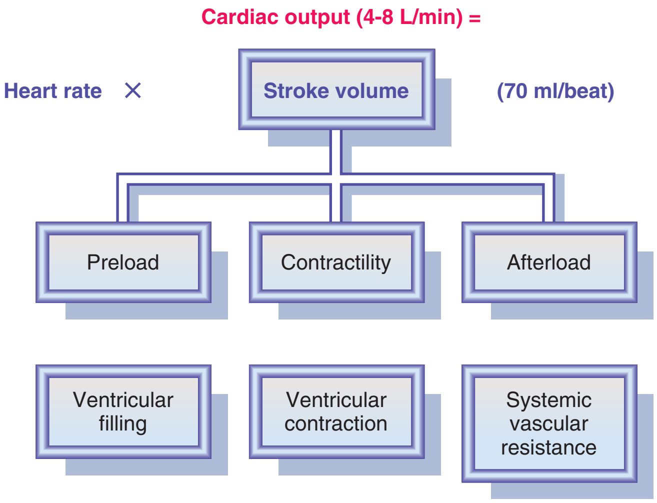

FIGURE XIV–3 Cardiac output and stroke volume.

CIRCULATION

There are two types of circulation—pulmonary and systemic. With pulmonary circulation, the heart pumps deoxygenated blood from the right ventricle through the pulmonary artery to the lungs. The pulmonary artery carries blood that has a high concentration of carbon dioxide. Oxygenated blood returns to the left atrium by the pulmonary vein.

With systemic circulation, also called *peripheral circulation*, the heart pumps blood from the left ventricle to the aorta and into the general circulation. Arteries and arterioles carry the blood to capillary beds. Nutrients in the capillary blood are transferred to cells in exchange for waste products. Blood returns to the heart through venules and veins.

BLOOD

Blood is composed of plasma, red blood cells (erythrocytes), white blood cells (leukocytes), and platelets. Plasma, made up of 90% water and 10% solutes, constitutes 55% of the total blood volume. The solutes in plasma include glucose, protein, lipids, amino acids, electrolytes, minerals, lactic and pyruvic acids, hormones, enzymes, oxygen, and carbon dioxide.

The major function of blood is to provide nutrients, including oxygen, to body cells. Most of the oxygen is carried on the hemoglobin of red blood cells (RBCs). White blood cells (WBCs) are the major defense mechanism of the body and act by engulfing microorganisms. They also produce antibodies. The platelets are large cells that cause blood to coagulate. RBCs have a life span of approximately 120 days, whereas the life span of a WBC is only 2 to 24 hours.

This unit is composed of five chapters dealing with drugs for cardiac disorders, diuretics and antihypertensive drugs, and drugs for circulatory disorders. Cardiac glycosides, antianginals, and antidysrhythmics are described in Chapter 42. Chapter 43 discusses the five categories of diuretics. Five major categories of antihypertensive agents are presented in Chapter 44. The five groups of drugs covered in Chapters 45 and 46 are the anticoagulants, antiplatelets, thrombolytics, antihyperlipidemics, and peripheral vasodilators.

CHAPTER

42

Cardiac Glycosides, Antianginals, and Antidysrhythmics

- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Differentiate the actions of cardiac glycosides, antianginal drugs, and antidysrhythmic drugs.
- Describe the signs and symptoms of digitalis toxicity.
- Compare the side effects and adverse reactions of nitrates, beta blockers, calcium channel blockers, quinidine, and procainamide.
- Apply the nursing process, including patient teaching, related to cardiac glycosides, antianginal drugs, and antidysrhythmic drugs.

OUTLINE

Cardiac Glycosides
- Nonpharmacologic Measures to Treat Heart Failure
- Digoxin
- Nursing Process: Patient-Centered Collaborative Care: Cardiac Glycosides: Digoxin
- Phosphodiesterase Inhibitors

Other Agents Used to Treat Heart Failure

Antianginal Drugs
- Types of Angina Pectoris
- Nonpharmacologic Measures to Control Angina
- Types of Antianginal Drugs
- Nursing Process: Patient-Centered Collaborative Care: Antianginals

Antidysrhythmic Drugs
- Cardiac Dysrhythmias
- Cardiac Action Potentials
- Types of Antidysrhythmic Drugs
- Nursing Process: Patient-Centered Collaborative Care: Antidysrhythmics

Three groups of drugs—cardiac glycosides, antianginals, and antidysrhythmics—are discussed in this chapter. Drugs in these groups regulate heart contraction, heart rate and rhythm, and blood flow to the myocardium (heart muscle).

CARDIAC GLYCOSIDES

Digitalis began being used as early as 1200 AD, making it one of the oldest drugs. It is still used in a purified form. Digitalis is obtained from the purple and white foxglove plant, and it can be poisonous. In 1785, William Withering of England used digitalis to alleviate "dropsy," edema of the extremities caused by kidney and cardiac insufficiency. Withering and his medical colleagues did not realize that dropsy was the result of heart failure, however. Digitalis preparations have come to be known for their effectiveness in treating heart failure (HF), also known as *cardiac failure* (CF), and previously referred to as **congestive heart failure (CHF).** When the heart muscle *(myocardium)* weakens and enlarges, it loses its ability to pump blood through the heart and into the systemic circulation. This is called **heart failure,** or pump failure. When compensatory mechanisms fail and the peripheral and lung tissues are congested, the condition is CHF. The causes of HF include chronic hypertension, myocardial infarction (MI), coronary artery disease (CAD), valvular heart disease, congenital heart disease, and arteriosclerosis.

Heart failure can be left-sided or right-sided. The patient has left-sided HF when the left ventricle does not contract sufficiently to pump the blood returned from the lungs and left atrium out through the aorta into the peripheral circulation; this causes excessive amounts of blood to back up into the lung tissue. Usually the patient has shortness of breath (SOB) and dyspnea. Right-sided HF occurs when the heart does not sufficiently pump the blood returned into the right atrium from the systemic circulation. As a result, the blood and its constituents are backed up into peripheral tissues, causing peripheral edema. Left-sided heart failure may lead to right-sided failure and vice versa. Myocardial hypertrophy resulting in *cardiomegaly* (increased heart size) can be a major problem associated with progressive HF.

In the cardiac physiology of HF, there is an increase in *preload* and *afterload*. An increased preload results from an excess of blood volume in the ventricle at the end of diastole. This occurs because of a pathologic increase in the stretching and thickening of the ventricular walls, which allows a greater filling pressure associated with a weakened heart. Increased afterload is an additional pressure or force in the ventricular wall caused by excess resistance in the aorta. This resistance must be overcome to open the aortic valve so blood can be ejected into the circulation. In 2001, the American College of Cardiology (ACC) and the American Heart Association (AHA) (ACC/AHA), classified HF in stages according to its severity. Table 42-1 lists the stages of HF according to the ACC/AHA. In the early stage of HF, there are no symptoms and no structural heart damage. Detailed information related to the staging process of HF can be found on the Internet at www.hearthope.com/about-heart-failure/nyha-scale.asp.

TABLE 42-1 ACC/AHA STAGES OF HEART FAILURE

STAGE	CHARACTERISTICS ACCORDING TO STAGES
1 (A)	High risk for HF without symptoms or structural heart disease
2 (B)	Some level of cardiac changes, e.g., decreased ejection fraction without symptoms of HF.
3 (C)	Structural heart disease with symptoms of HF, i.e., fatigue, shortness of breath, edema, and decrease in physical activity.
4 (D)	Severe structural heart disease and marked symptoms of HF at rest.

ACC, American College of Cardiology; *AHA,* American Heart Association; *HF,* heart failure.

Naturally occurring **cardiac glycosides** are found in a number of plants, including *Digitalis*. Also called *digitalis glycosides,* this group of drugs inhibits the sodium-potassium pump, resulting in an increase in intracellular sodium. This increase leads to an influx of calcium, causing the cardiac muscle fibers to contract more efficiently. Digitalis preparations have three effects on heart muscle: (1) positive **inotropic** action (*increases* myocardial contraction stroke volume), (2) negative **chronotropic** action (*decreases* heart rate), and (3) negative **dromotropic** action (*decreases* conduction of heart cells). The increase in myocardial contractility strengthens cardiac, peripheral, and kidney function by enhancing cardiac output, decreasing preload, improving blood flow to the periphery and kidneys, decreasing edema, and promoting fluid excretion. As a result, fluid retention in the lung and extremities is decreased. Digoxin does not prolong life. It acts by increasing the force and velocity of myocardial systolic contraction.

Digoxin is a secondary drug for HF. First-line drugs used to treat acute HF include intravenous inotropic agents (dopamine and dobutamine) and phosphodiesterase inhibitors, such as milrinone. Other drugs prescribed for HF include oral diuretics, beta blockers, ACE inhibitors, angiotensin-receptor blockers (ARBs), calcium channel blockers, and vasodilators, all of which are more convenient to self-administer. Oral administration allows the patient to go home on these medications.

Cardiac glycosides are also used to correct **atrial fibrillation** (cardiac dysrhythmia with rapid uncoordinated contractions of atrial myocardium) and **atrial flutter** (cardiac dysrhythmia with rapid contractions of 200 to 300 beats/min). This is accomplished by the negative chronotropic effects (decreased heart rate) and negative dromotropic effects (decreased conduction through the atrioventricular [AV] node).

When digoxin cannot convert atrial fibrillation to normal heart rhythm, the goal is to slow the heart rate by decreasing electrical impulses through the AV node. For management of atrial fibrillation, a calcium channel blocker such as verapamil (Calan) may be prescribed. To prevent thromboemboli resulting from atrial fibrillation, warfarin (Coumadin) is prescribed concurrently with other drug therapy. Warfarin is discussed in Chapter 45.

Nonpharmacologic Measures to Treat Heart Failure

Nondrug therapy is an integral part of the regimen for controlling HF. The nondrug component of the regimen should be tailored to meet the needs of each patient, but the following are some general recommendations. The patient should limit salt intake to 2 g/day, which is approximately 1 teaspoon. Alcohol intake should be either decreased to 1 drink per day or completely avoided, because excessive alcohol use can lead to cardiomyopathy. Fluid intake may be restricted. Smoking should be avoided, because it deprives the heart of oxygen (O_2). Mild exercise, such as walking or bicycling, is recommended as well as restricting fluids in severe conditions. Obesity may increase cardiovascular problems if it is associated with unhealthy behaviors; thus, obese patients should modify their behaviors as needed. Mild exercise, such as walking or bicycling, is recommended.

Laboratory Tests

Atrial Natriuretic Hormone or Peptide. Reference value: 20 to 77 pg/mL; 20 to 77 ng/L (SI units). An elevated atrial natriuretic hormone (ANH) or peptide (ANP) may confirm HF. ANH is secreted from the atria of the heart and acts as an antagonist to renin and aldosterone. It is released during expansion of the atrium, produces vasodilation, and increases glomerular filtration rate. Results of ANH secretion include a large volume of urine that decreases blood volume and blood pressure.

Brain Natriuretic Peptide. Reference values: Desired value: less than 100 pg/mL; positive value: greater than 100 pg/mL. The brain natriuretic peptide (BNP) is primarily secreted from atrial cardiac cells and, when tested, aids in the diagnoses of HF. Diagnosing HF is difficult in persons with lung disease who are experiencing dyspnea and in those who are obese or older. An elevated BNP helps differentiate that dyspnea is due to HF rather than lung dysfunction. Frequently the BNP is higher than 100 pg/mL in women who are 65 years of age or older. An 80-year-old woman may have a BNP of 160 pg/mL. However, the BNP is markedly higher (i.e., 400 pg/mL) in HF. BNP is considered a more sensitive test than ANP for diagnosing HF. Today there is a bedside/emergency department machine to measure BNP.

SAFETY: Preventing Medication Errors

Do not confuse…

- **digoxin** with **digitoxin.** Both drugs are cardiac glycosides. **Digoxin** (Lanoxin) is usually the first-choice drug, because its half-life is 36 hours, whereas the half-life of **digitoxin** is 4 to 9 days. **Digitoxin** is rarely prescribed and is not available in the United States.

Digoxin

Prototype Drug Chart 42-1 gives the pharmacologic data for digoxin, a cardiac glycoside.

Pharmacokinetics The absorption rate of digoxin in oral tablet form is 70%. The rate is 90% in liquid and capsule form. The protein-binding power for digoxin is 30%. The half-life is 30 to 40 hours. Because of its long half-life, drug accumulation can occur. Side effects should be closely monitored to detect digitalis toxicity. Patients should be made aware of side effects that need to be reported to the health care provider. Serum digoxin levels are most commonly drawn when actual digitoxicity is suspected. This allows the health care provider to ascertain the extent of such toxicity and to confirm elimination of the drug after it is stopped or decreased in dosage (see the Digitalis [Digoxin] Toxicity section later in this chapter).

Thirty percent of digoxin is metabolized by the liver, and 50% to 70% is excreted by the kidneys mostly unchanged. Kidney dysfunction can affect the excretion of digoxin. Thyroid dysfunction can alter the metabolism of cardiac glycosides. For patients with hypothyroidism, the dose of digoxin should be decreased; in hyperthyroidism, the dose may need to be increased.

Pharmacodynamics In patients with a failing heart, cardiac glycosides increase myocardial contraction, which increases cardiac output and improves circulation and tissue perfusion. Because these drugs decrease conduction through the AV node, the heart rate decreases. The onset and peak actions of oral and intravenous (IV) digoxin vary. The **therapeutic serum level** is 0.8 to 2.0 ng/mL for digoxin. To treat HF, the lower serum therapeutic levels should be obtained, and for atrial fibrillation, the higher therapeutic serum levels are required.

Digoxin can be administered orally or IV. Table 42-2 lists the digitalis preparations and their dosages, uses, and considerations.

Digitalis (Digoxin) Toxicity

Overdose or accumulation of digoxin causes digitalis toxicity. Signs and symptoms include anorexia, diarrhea, nausea and vomiting, **bradycardia** (pulse rate below 60 beats/min), premature ventricular contractions, cardiac dysrhythmias, headaches, malaise, blurred vision, visual illusions (white, green, yellow halos around objects), confusion, and delirium. Older adults are more prone to toxicity.

Cardiotoxicity is a serious adverse reaction to digoxin; ventricular dysrhythmias result. Three cardiac-altered functions can contribute to digoxin-induced ventricular dysrhythmias: (1) suppression of AV conduction, (2) increased automaticity, and (3) a decreased refractory period in ventricular muscle. The antidysrhythmics phenytoin and lidocaine are effective in treating digoxin-induced ventricular dysrhythmias. Lidocaine should be limited to short-term treatment.

Antidote for Cardiac/Digitalis Glycosides

Digoxin immune Fab (ovine, Digibind) may be given to treat severe digitalis toxicity. This agent binds with digoxin to form complex molecules that can be excreted in the urine; thus, digoxin is unable to bind at the cellular site of action. Signs and symptoms of digoxin toxicity should be reported promptly to the health care provider. Serum digoxin levels

PROTOTYPE DRUG CHART 42-1

Digoxin

Drug Class

Cardiac glycoside
Trade Name: Lanoxin
Pregnancy Category: C

Dosage

A: PO: 0.5-1 mg initially in 2 divided doses (digitalization); maint: 0.125-0.5 mg/d
IV: Same as PO dose but given over 5 min
Older adults: 0.125 mg/d
C: 1 mo-2y: PO: 0.01-0.02 mg/kg in 3 divided doses; maint: 0.012 mg/kg/d in 2 divided doses
C: IV: Dosage varies
C: 2-10y: PO: 0.012-0.04 mg/kg in divided doses
Pediatric doses are usually ordered in mcg in elixir form.

Contraindications

Ventricular dysrhythmias, second- or third-degree heart block
Caution: AMI, renal disease, hypothyroidism, hyperthyroidism, hepatic dysfunction, bradycardia, hypokalemia

Drug-Lab-Food Interactions

Drug: Increase digoxin serum level with quinidine, flecainide, verapamil; decrease digoxin absorption with antacids, colestipol; increase risk for digoxin toxicity with thiazide diuretics, loop diuretics
Lab: Hypokalemia, hypomagnesemia, hypercalcemia can increase digitalis (digoxin) toxicity

Pharmacokinetics

Absorption: PO: tablet: 60%-70%;
PO: liquid: 90%
PO: capsule: 90%-100%
Distribution: PB: 20%-30%
Metabolism: t½: 30-40 h
Excretion: 70% in urine; 30% by liver metabolism

Pharmacodynamics

PO: Onset: 30 min–2 h
Peak: 2-6 h
Duration: UK
IV: Onset: 5-30 min
Peak: UK
Duration: UK

Therapeutic Effects/Uses

To treat HF, atrial fibrillation
Mode of Action: Inhibits sodium-potassium ATPase, promoting increased force of cardiac contraction, cardiac output, and tissue perfusion; decreases ventricular rate

Side Effects

Anorexia, nausea, vomiting, diarrhea, abdominal pain, headache, blurred vision (yellow-green halos), diplopia, photophobia, drowsiness, dizziness, fatigue, confusion

Adverse Reactions

Bradycardia, visual disturbances
Life-threatening: Atrioventricular block, cardiac dysrhythmias

A, Adult; *AMI,* acute myocardial infarction; *ATPase,* adenosine triphosphatase; *C,* child; *d,* day; *HF,* heart failure; *h,* hour; *IV,* intravenous; *maint,* maintenance; *min,* minute; *mo,* month; *PB,* protein-binding; *PO,* by mouth; *t ½,* half-life; *y,* year.

should be closely monitored. Digitalis toxicity may result in first-degree, second-degree, or complete heart block.

Drug Interactions

Drug interaction with digitalis preparations can cause digitalis toxicity. Many of the potent diuretics, such as furosemide (Lasix) and hydrochlorothiazide (Esidrix, Microzide), promote the loss of potassium from the body. The resultant **hypokalemia** (low serum potassium level) increases the effect of digoxin at its myocardial cell site of action, resulting in digitalis toxicity. Cortisone preparations taken systemically promote sodium retention and potassium excretion or loss and can also cause hypokalemia. Patients who take digoxin along with a potassium-wasting diuretic or a cortisone drug should consume foods rich in potassium or take potassium supplements to avoid hypokalemia and digitalis toxicity. Antacids can decrease digitalis absorption if taken at the same time. To prevent this problem, doses should be staggered.

Phosphodiesterase Inhibitors

Phosphodiesterase inhibitors are another positive inotropic group of drugs given to treat acute HF. This drug group inhibits the enzyme phosphodiesterase, promoting a positive inotropic response and vasodilation. A drug in this group is milrinone lactate. This drug increases stroke volume and cardiac output and promotes vasodilation. It is administered IV for no longer than 48 to 72 hours. Severe cardiac dysrhythmias might result from the use of phosphodiesterase inhibitors, so the patient's electrocardiogram (ECG) and cardiac status should be closely monitored.

TABLE 42-2 CARDIAC GLYCOSIDES AND INOTROPIC AGENTS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Rapid-Acting Digitalis		
digoxin (Lanoxin)	See Prototype Drug Chart 42-1.	
Phosphodiesterase Inhibitors (Positive Inotropic Bipyridines)		
milrinone lactate	A: IV: Initially: 50 mcg/kg/over 10 min Continuous infusion: 0.375-0.75 mcg/kg/min with 0.45%-0.9% saline	For short-term treatment of HF. May be given before heart transplantation. Heart rate and blood pressure should be closely monitored. Pregnancy category: C; PB: 70%; t½: 1.5-2.5 h
Atrial Natriuretic Peptide Hormones		
nesiritide (Natrecor)	A: IV bolus: 2 mcg/kg, followed by 0.01 mcg/kg/min, by IV infusions; *max:* 0.03 mcg/kg/min continuous IV infusion	To treat acute HF by increasing sodium loss. Useful in managing dyspnea at rest. Causes vasodilation. Contraindicated for patients with systolic BP <90 mm Hg. Pregnancy category: C; PB: UK; t½: 18 min
Antidote for Digitalis Toxicity		
digoxin immune Fab (Digibind)	A: IV: 760-800 mg IV diluted in 50 mL NSS. Infuse over 30 min	For serious digitalis toxicity. Agent binds with digoxin to form complex molecules. (Serum digoxin level >2 ng indicative of digitalis toxicity.) Onset of action: 30 min; duration of action: 3-4 d. Pregnancy category: C; PB: UK; t½: 23 h

A, Adult; *BP,* blood pressure; *d,* day; *HF,* heart failure; *inf,* infusion; *IV,* intravenous; *LD,* loading dose; *maint,* maintenance; *min,* minute; *NSS,* normal saline solution; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *>,* greater than.

OTHER AGENTS USED TO TREAT HEART FAILURE

Vasodilators, angiotensin-converting enzyme (ACE) inhibitors, angiotensin II receptor antagonists (blockers), diuretics (thiazides, furosemide), spironolactone (Aldactone), and some beta blockers are other drug groups prescribed to treat HF.

Vasodilators can be used to treat HF. The vasodilators decrease venous blood return to the heart resulting in a decrease in cardiac filling, ventricular stretching (preload), and oxygen demand on the heart. Arteriolar dilators act in three ways: (1) to reduce cardiac afterload, which increases cardiac output; (2) to dilate the arterioles of the kidneys, which improves renal perfusion and increases fluid loss; and (3) to improve circulation to the skeletal muscles.

Nursing Process
Patient-Centered Collaborative Care

Cardiac Glycosides: Digoxin

Assessment

- Obtain a drug and herbal history. Report if drug-drug or drug-herb interaction is probable. If patient is taking digoxin and a potassium-wasting diuretic or cortisone drug, hypokalemia might result, causing digitalis toxicity. Low serum potassium level enhances action of digoxin. Patients taking a thiazide and/or cortisone with digoxin should take a potassium supplement.
- Obtain a baseline pulse rate for future comparisons. Apical pulse should be taken for a full minute and should be greater than 60 beats/min.
- Assess for signs and symptoms of digitalis toxicity. Common symptoms include anorexia, nausea, vomiting, bradycardia, cardiac dysrhythmias, and visual disturbances. Report symptoms immediately to the health care provider.

Nursing Diagnoses

- Decreased cardiac output related to decreased cardiac pumping ability
- Ineffective peripheral tissue perfusion related to decreased cardiac pumping ability
- Anxiety related to threat to cardiac health status

Planning

- Patient will check pulse rate daily before taking digoxin.
- Patient will report pulse rate when less than 60 beats/min or a marked decline in pulse rate.
- Patient will eat foods high in potassium to maintain a desired serum potassium level (see Patient Teaching and Diet sections).

Nursing Interventions

- Ascertain apical pulse rate before administering digoxin. Do *not* administer if pulse rate <60 beats/min.
- Determine signs of peripheral and pulmonary edema, which indicate HF is present.
- Monitor serum digoxin level (normal therapeutic drug range is 0.8 to 2 ng/mL). A serum digoxin level greater than 2 ng/mL is indicative of digitalis toxicity.

- Monitor serum potassium level (normal range is 3.5 to 5.3 mEq/L), and report if hypokalemia (<3.5 mEq/L) is present.

Patient Teaching

General

- Explain to patient the importance of adherence to drug therapy. A visiting nurse may ensure that medications are properly taken.
- Advise patient to avoid adverse drug interactions by not taking over-the-counter (OTC) drugs without first consulting health care provider.
- Keep drugs out of reach of small children. Request childproof bottles.
- Teach patient or child's parent to check pulse rate before administering drug.
- Inform patient of possible herb-drug interactions (Herbal Alert 42-1).

Self-Administration

- Teach patient how to check pulse rate before taking digoxin and to notify health care provider if pulse rate is <60 beats/min or irregular.

Side Effects

- Instruct patient to report side effects: pulse rate <60 beats/min, nausea, vomiting, headache, diarrhea, and visual disturbances, including diplopia.

Diet

- Advise patient to eat foods high in potassium, such as fresh and dried fruits, fruit juices, and vegetables, including potatoes.

Cultural Considerations

- Analyze conflicts in values and beliefs, and use culturally consistent communication practices. It is essential that patients taking digoxin, diuretics, and potassium supplements for HF do not miss any doses of their medication. Patient should be fully aware of adverse effects and readily report them to the health care provider.
- Validate patient's understanding of purposes for taking these drugs. Be aware of potential cultural differences related to response to authority and involvement of family members. For example, Amish people often respect authority and may follow instructions without question, but family members must be involved in decision making.

Evaluation

- Evaluate the effectiveness of digoxin by noting patient's response to drug (decreased heart rate, decreased rales) and absence of side effects. Continue monitoring pulse rate.

HERBAL ALERT 42-1

Cardiac Glycosides: Digoxin

- Ginseng may falsely elevate digoxin levels.
- St. John's wort decreases absorption of digoxin and thus decreases serum digoxin level.
- Psyllium (Metamucil) may decrease digoxin absorption.
- Hawthorn may increase the effect of digoxin.
- Licorice can potentiate the effect of digoxin. It promotes potassium loss (hypokalemia), which increases the effect of digoxin. It may cause digitalis toxicity.
- Aloe may increase the risk of digitalis toxicity. It increases potassium loss, which increases the effect of digoxin.
- Ma-huang or ephedra increases the risk of digitalis toxicity.
- Goldenseal may decrease the effects of cardiac glycosides and increase the effects of antidysrhythmics.

ACE inhibitors are usually prescribed for HF. ACE inhibitors dilate venules and arterioles, improving renal blood flow and decreasing blood fluid volume. They also moderately decrease the release of aldosterone, which in turn reduces sodium and fluid retention.

ACE inhibitors can increase potassium levels, so serum potassium levels should be monitored, especially if potassium-sparing diuretics (e.g., spironolactone [Aldactone]) are being taken concurrently. Angiotensin II receptor blockers (ARBs), such as valsartan (Diovan) and candesartan (Atacand) have been approved for HF in patients who cannot tolerate ACE inhibitors. Refer to Chapter 44 for a complete discussion of ACE inhibitors and ARBs.

Diuretics are the first-line drug treatment for reducing fluid volume. They are frequently prescribed with digoxin or other agents.

Spironolactone (Aldactone), a potassium-sparing diuretic, is used in treating moderate to severe HF. Aldosterone secretions are increased in HF. This promotes body loss of potassium and magnesium needed by the heart and increases sodium and water retention. Spironolactone blocks the production of aldosterone. This drug improves heart rate variability and decreases myocardial fibrosis by its cardioprotective effect of blocking aldosterone in the heart and blood vessels to promote cardiac remodeling. The recommended dose is 12.5 to 25 mg/day. Occurrence of hyperkalemia (excess serum potassium) is rare unless the patient is receiving 50 mg/day and has renal insufficiency. However, the serum potassium level should be closely monitored.

In the past, all beta blockers were contraindicated for patients with HF, because this drug class reduces cardiac contractility. With dosage control, beta blockers (carvedilol [Coreg], metoprolol [Lopressor, Toprol-XL], and bisoprolol [Zebeta]) have been shown to improve cardiac performance. Doses should be low initially and gradually increased. It may take 1 to 3 months for a beneficial effect to develop. Refer to Chapters 18 and 44 for more information on beta blockers.

Nesiritide (Natrecor) is an atrial natriuretic peptide hormone that inhibits antidiuretic hormone (ADH) by increasing urine sodium loss. Its effect in correcting HF is achieved by promoting vasodilation, natriuresis, and diuresis. It is useful for treating patients who have acute decompensated HF with dyspnea at rest or who have dyspnea with little physical exertion.

BiDil, a combination of hydralazine (for blood pressure) and isosorbide dinitrate (a dilator to relieve heart pain) has received FDA approval for treating HF, especially in African Americans. African Americans have more than twice the rate of HF as whites, and a research study has shown this drug to be effective in treating HF in the African-American population.

ANTIANGINAL DRUGS

Antianginal drugs are used to treat **angina pectoris.** This is a condition of acute cardiac pain caused by inadequate blood flow to the myocardium due to either plaque occlusions within or spasms of the coronary arteries. With decreased blood flow, there is a decrease in oxygen to the myocardium, which results in pain. Anginal pain is frequently described by the patient as tightness, pressure in the center of the chest, and pain radiating down the left arm. Referred pain felt in the neck and left arm commonly occurs with severe angina pectoris. Anginal attacks may lead to MI (*heart attack*). Anginal pain usually lasts for only a few minutes. Stress tests, echocardiogram, cardiac profile laboratory tests, and cardiac catheterization may be needed to determine the degree of blockage in the coronary arteries and then also to treat the condition.

Types of Angina Pectoris

The frequency of anginal pain depends on many factors, including the type of angina. There are three types of angina:

- *Classic (stable):* Occurs with predictable stress or exertion
- *Unstable (preinfarction):* Occurs frequently with progressive severity unrelated to activity; unpredictable regarding stress/exertion and intensity
- *Variant (Prinzmetal, vasospastic):* Occurs during rest

The first two types are caused by a narrowing or partial occlusion of the coronary arteries; variant angina is caused by vessel spasm (vasospasm). It is common for a patient to have both classic and variant angina. Unstable angina often indicates an impending MI. This is an emergency that needs immediate medical intervention.

Nonpharmacologic Measures to Control Angina

A combination of pharmacologic and nonpharmacologic measures is usually necessary to control and prevent anginal attacks. Nonpharmacologic methods of decreasing anginal attacks are to avoid heavy meals, smoking, extreme weather changes, strenuous exercise, and emotional upset. Proper nutrition, moderate exercise (only after consulting with a health care provider), adequate rest, and relaxation techniques are used as preventive measures.

Types of Antianginal Drugs

Antianginal drugs increase blood flow either by increasing oxygen supply or by decreasing oxygen demand by the myocardium. Three types of antianginals are nitrates, beta blockers, and calcium channel blockers. The major systemic effect of nitrates is a reduction of venous tone, which decreases the workload of the heart and promotes vasodilation. Beta blockers and calcium channel blockers decrease the workload of the heart and decrease oxygen demands.

Nitrates and calcium channel blockers are effective in treating variant (vasospastic) angina pectoris. Beta blockers are not effective for this type of angina and may aggravate it. With stable angina, beta blockers can effectively be used to prevent angina attacks. Table 42-3 lists the effects of antianginal drug groups on angina.

With unstable angina, immediate medical care is necessary. Nitrates are usually given sublingually and intravenously as needed. If the cardiac pain continues, a beta blocker is given intravenously, and if the patient is unable to tolerate beta blockers, a calcium channel blocker may be substituted.

Nitrates

Nitrates, developed in the 1840s, were the first agents used to relieve angina. They affect coronary arteries and blood vessels in the venous circulation. Nitrates cause generalized vascular and coronary vasodilation, which increases blood flow through the coronary arteries to the myocardial cells. This group of drugs reduces myocardial ischemia but can cause hypotension.

TABLE 42-3 **EFFECTS OF ANTIANGINAL DRUG GROUPS ON ANGINA**

DRUG GROUPS	VARIANT (VASOSPASTIC) ANGINAS	CLASSIC (STABLE) ANGINAS
Nitrates	Relaxation of coronary arteries, which decreases vasospasms and increases O_2 supply	Dilation of veins, which decreases preload and decreases O_2 demand
Beta blockers	Not effective	Decreases heart rate and contractility, which decreases O_2 demand
Calcium channel blockers	Relaxation of coronary arteries, which decreases vasospasms and increases O_2 supply	Dilation of arterioles, which decreases afterload and decreases O_2 demand. Verapamil and diltiazem decrease heart rate and contractility

O_2, Oxygen.

SAFETY: Preventing Medication Errors

Do not confuse…

- **Nitrostat** and **Nystatin.** Nitrostat is a nitroglycerin drug that promotes coronary vasodilation and thus increases blood flow to the coronary arteries. Nystatin is an antifungal antibiotic that has fungistatic and fungicidal activity against yeasts and fungi.

The sublingual (SL) nitroglycerin tablet, which is absorbed under the tongue, comes in various dosages, but the average prescribed dose is 0.4 mg following cardiac pain. If pain has not subsided or worsened, then 911 should be called. The effects of SL nitroglycerin last for 10 minutes. The SL tablets decompose when exposed to heat and light, so they must be kept in their original airtight glass containers. The tablets themselves are normally dispensed in these original glass containers, which have screw-cap tops that are not childproof. This facilitates emergency use by older adults who may have reduced manual dexterity and are experiencing an anginal attack. After a dose of nitroglycerin, the patient may experience dizziness, faintness, or headache as a result of the peripheral vasodilation. If pain persists, the patient should immediately call for medical assistance.

Sublingual (SL) nitroglycerin is the most commonly used nitrate. It is not swallowed, because it undergoes first-pass metabolism by the liver, which decreases its effectiveness. Instead, it is readily absorbed into the circulation through the SL vessels. Nitroglycerin is also available in other forms: topical (ointment, transdermal patch), translingual, oral extended-release capsule and tablet, aerosol spray (inhalation), and IV. Prototype Drug Chart 42-2 summarizes the action of nitroglycerin (nitrates).

There are various types of organic nitrates. Isosorbide dinitrate (Isordil) can be administered in SL tablet form and is also available as chewable tablets, immediate-release tablets, and sustained-release tablets and capsules. Isosorbide mononitrate (Imdur) can be given orally in immediate-release and sustained-release tablets.

Pharmacokinetics Nitroglycerin, taken SL, is absorbed rapidly and directly into the internal jugular vein and the right atrium. Approximately 40% to 50% of nitrates absorbed through the gastrointestinal (GI) tract are inactivated by first-pass metabolism in the liver. The nitroglycerin in Nitro-Bid ointment and in the Transderm-Nitro patch is absorbed slowly through the skin. It is excreted primarily in the urine.

Pharmacodynamics Nitroglycerin acts directly on the smooth muscle of blood vessels, causing relaxation and dilation. It decreases cardiac **preload** (amount of blood in the ventricle at the end of diastole) and **afterload** (peripheral vascular resistance) and reduces myocardial O_2 demand. With dilation of the veins, there is less blood return to the heart, and with dilation of the arteries, there is less vasoconstriction and resistance.

The onset of action of nitroglycerin depends on the method of administration. With SL and IV use, the onset of action is rapid (1 to 3 minutes); it is slower with the transdermal method (30 to 60 minutes). The duration of action of the transdermal nitroglycerin patch is approximately 24 hours. Because Nitro-Bid ointment is effective for only 6 to 8 hours, it must be reapplied three to four times a day. The use of Nitro-Bid ointment has declined since the advent of the transdermal nitroglycerin patch, which is applied only once a day. It is important to note that the patch should be removed nightly to allow for an 8- to 12-hour nitrate-free interval. This is also true for most other forms of nitroglycerin. This is necessary to avoid tolerance associated with uninterrupted use or continued dosage increases of nitrate preparations. Table 42-4 lists the nitrates and their dosages, uses, and considerations.

Side Effects and Adverse Reactions

Headaches are one of the most common side effects of nitroglycerin, but they may become less frequent with continued use. Otherwise acetaminophen may provide some relief. Other side effects include hypotension, dizziness, weakness, and faintness. When nitroglycerin ointment or transdermal patches are discontinued, the dose should be tapered over several weeks to prevent the rebound effect of severe pain caused by **myocardial ischemia** (lack of blood supply to the heart muscle). In addition, *reflex tachycardia* may occur if the nitrate is given too rapidly. The heart rate increases greatly because of overcompensation of the cardiovascular system.

Drug Interactions

Beta blockers, calcium channel blockers, vasodilators, and alcohol can enhance the hypotensive effect of nitrates. IV nitroglycerin may antagonize the effects of heparin.

Beta Blockers

Beta-adrenergic blockers block the beta$_1$- and beta$_2$-receptor sites. **Beta blockers** decrease the effects of the sympathetic nervous system by blocking the action of the catecholamines (epinephrine and norepinephrine), thereby decreasing the heart rate and blood pressure. They are used as antianginal, antidysrhythmic, and antihypertensive drugs. Beta blockers are effective as antianginals because by decreasing the heart rate and myocardial contractility, they reduce the need for oxygen consumption and consequently reduce anginal pain. These drugs are most useful for classic (stable) angina.

Beta blockers should not be abruptly discontinued. The dose should be tapered over a specified number of days to avoid reflex tachycardia and recurrence of anginal pain. Patients who have decreased heart rate and blood pressure usually cannot take beta blockers. Patients who have second- or third-degree AV block should not take beta blockers.

Beta blockers, discussed in detail in Chapter 18, are subdivided into *nonselective* beta blockers (block beta$_1$ and beta$_2$) and *selective* (cardiac) beta blockers (block beta$_1$).

Examples of nonselective beta blockers are propranolol (Inderal), nadolol (Corgard), and pindolol (Visken). These drugs decrease the heart rate and can cause bronchoconstriction. The cardioselective beta blockers act more strongly on the beta$_1$ receptor, which decreases heart rate but avoids bronchoconstriction, because of their lack of activity at the beta$_2$ receptor. Examples of selective beta blockers are atenolol (Tenormin) and metoprolol (Lopressor, Toprol-XL). Selective beta blockers are the group of choice for controlling angina pectoris. Table 42-4 lists the beta blockers most frequently used for angina and their dosages, uses, and considerations.

PROTOTYPE DRUG CHART 42-2

Nitroglycerin

Drug Class

Antianginal

Trade Names: Nitrostat, Nitro-Bid, Transderm-Nitro patch, NTG, 🍁 Nitrogard SR

Pregnancy Category: C

Dosage

A: PO/SL: 0.3, 0.4, 0.6 mg; repeat q5min × 3 as needed;

SR: 2.5- 6.5 mg, 2-4 times/d

IV: Initially: 5 mcg/min; dose may be increased

Ointment: 2% 1-2 inches to chest or thigh area

Patch: 2.5-15 mg/d to chest or thigh area

Contraindications

Increased intracranial pressure, severe anemia, cardiomyopathy

Caution: Severe renal or hepatic disease, acute MI, severe hypotension, hypovolemia, pregnancy, breastfeeding

Drug-Lab-Food Interactions

Drug: Increase effect with alcohol, beta blockers, calcium channel blockers, antihypertensives, aspirin, benzodiazepines, vasodilators; decrease effects of heparin

Herbs: hawthorn increases nitroglycerin levels

Pharmacokinetics

Absorption: SL: Greater than 75% absorbed; ointment and patch: slow absorption

Pharmacodynamics

SL: Onset: 1-3 min
Peak: 4 min
Duration: 30 min
SR Cap: Onset: 20-45 min
Duration: 8-12 h
Ointment: Onset: 20-60 min
Peak: 1-2 h
Duration: 6-8 h
Patch: Onset: 30-60 min
Peak: 1-2 h
Duration: 20-24 h
Distribution: PB: 60%
Metabolism: $t_{1/2}$: 1-4 min
Excretion: Liver and urine
IV: Onset: 1-3 min
Duration: 3-5 min

Therapeutic Effects/Uses

To control angina pectoris (anginal pain)

Mode of Action: Decreases myocardial demand for oxygen; decreases preload by dilating veins, indirectly decreasing afterload

Side Effects

Nausea, vomiting, headache, blurred vision, dizziness, syncope, weakness, diaphoresis, flushing, confusion, pallor, rash, dry mouth, palpitations, tolerance

Adverse Reactions

Hypotension, reflex tachycardia, paradoxical bradycardia

Life-threatening: Circulatory collapse

A, Adult; *AMI,* acute myocardial infarction; *cap,* capsule; *d,* day; *h,* hour; *IV,* intravenous; *MI,* myocardial infarction; *min,* minute; *NTG,* nitroglycerin; *PB,* protein-binding; *PO,* by mouth; *SL,* sublingual; *SR,* sustained-release; $t_{1/2}$, half-life; 🍁, Canadian drug name.

TABLE 42-4 ANTIANGINALS

GENERIC (BRAND)	ROUTE AND DOSAGES	USES AND CONSIDERATIONS
Nitrates		
Short Acting		
nitroglycerin (Nitrostat, Nitro-Bid, Transderm-Nitro)	See Prototype Drug Chart 42-2.	
Long Acting		
isosorbide dinitrate (Isordil, Sorbitrate)	A: PO: IR: Initially 5-20 mg b.i.d/t.i.d.; maint: 10-40 mg b.i.d./t.i.d. A: SL: 2.5-10 mg q2-3h PRN A: SR: 40-160 mg/d	To prevent anginal attacks. Can lower blood pressure. Tolerance builds up over time. Headaches, dizziness, lightheadedness, and flush may occur. Pregnancy category: C; PB: UK; $t_{1/2}$: 1-4 h

Continued

TABLE 42-4 ANTIANGINALS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGES	USES AND CONSIDERATIONS
isosorbide mononitrate (Imdur)	A: PO: IR: 5-20 mg b.i.d.; *max:* 40 mg/d A: PO: SR: 30-60 mg in morning; *max:* 240 mg/d	To prevent anginal attacks. SR form provides controlled delivery and a 6-hour drug-free period, which helps reduce drug tolerance and increase effectiveness. Pregnancy category: C; PB: 5%; t½: 5 h
Beta-Adrenergic Blockers		
atenolol (Tenormin) (beta$_1$)	A: PO: 25-100 mg/d; *max:* 200 mg/d	To control angina pectoris. Also effective in managing hypertension. Closely monitor blood pressure and heart rate. Cardioselective drug; blocks beta$_1$. Can be used by patients with asthma. Pregnancy category: D; PB: 5%-15%; t½: 6-7 h
metoprolol tartrate (Lopressor, Toprol XL) (beta$_1$)	A: PO: 50-100 mg in 2 divided doses; may increase to 100-400 mg/d A: PO: ER: 100 mg/d; may increase to 400 mg/d A: IV: 5 mg q2min; followed in 1-2 h by PO: 25-50 mg q6h	Similar to atenolol in blocking beta$_1$. High doses of metoprolol can affect beta$_2$ and could cause bronchoconstriction. Can reduce cardiac oxygen demand, which decreases heart rate and contractility. Pregnancy category: C; PB: 12%; t½: 3-7 h
nadolol (Corgard) (beta$_1$ and beta$_2$)	A: PO: 40 mg/d; may increase dose; *max:* 240-320 mg/d in divided doses	For angina pectoris and hypertension. Pregnancy category: C; PB: 30%; t½: 10-24 h
propranolol HCl (Inderal) (beta$_1$ and beta$_2$)	A: PO: Initially: 40 mg b.i.d.; maint: 160-480 mg/d in 2-3 divided doses; *max:* 640 mg/d SR: 80-160 mg/d; may increase to 120-160 mg/d; *max:* 640 mg/d	First beta blocker; blocks beta$_1$ and beta$_2$. No longer drug of choice to prevent angina because drug poses risk for bronchospasm. Monitor heart rate, blood pressure, and respiratory status. Pregnancy category: C; PB: 90%; t½: 2-6 h
Calcium Channel Blockers		
amlodipine (Norvasc)	A: PO: Initially: 5 mg/d; maint: 5-10 mg/d; *max:* 10 mg/d Older adults: Initially: 2.5 mg/d; maint: 2.5-10 mg/d	For angina pectoris and hypertension. May be given with another antianginal or antihypertensive drug. Pregnancy category: C; PB: 93%; t½: 30-50 h
diltiazem HCl (Cardizem)	A: PO: 30-60 mg q.i.d.; may increase to 360 mg/d in 4 divided doses; *max:* 480 mg/d SR: 60 mg q12h; *max:* 360 mg/d CR: 120-180 mg/d; *max:* 360 mg/d	For angina pectoris. Hypotensive effect not as severe as with nifedipine. Monitor kidney function. Pregnancy category: C; PB: 70%-80%; t½: 3.5-9 h
felodipine (Felendil XL)	A: PO: Initially: 5 mg/d single dose; maint: 2.5-10 mg/d; *max:* 10 mg/d Older adults: Initially: 2.5 mg/d; *max:* 10 mg/d	To treat chronic angina pectoris and manage hypertension. Reduces O$_2$ demand by the heart. Potent peripheral vasodilator; increases heart rate and myocardial contractility. Pregnancy category: C; PB: >99%; t½: 10-16 h
isradipine (DynaCirc)	A: PO: 2.5-7.5 mg b.i.d.; *max:* 10 mg/d	Primary use is to treat hypertension. Also given for angina pectoris. Pregnancy category: C; PB: 95%; t½: 8 h
nicardipine HCl (Cardene SR, Cardene IV)	A: PO: 20 mg t.i.d.; maint: 20-40 mg t.i.d. A: PO: SR: 30 mg b.i.d.; maint: 30-60 mg b.i.d. A: IV: Initially 5 mg/h infusion; *max:* 15 mg/h	For angina pectoris. May be used alone or in combination with other antianginals. Also used for hypertension. Peripheral edema, headache, dizziness, and lightheadedness may occur. Pregnancy category: C; PB: 95%; t½: 2-4 h
nifedipine (Procardia, Adalat)	A: PO: Initially 10 mg t.i.d.; 30 mg q6-8h; *max:* 180 mg/d A: PO: ER: 30-60 mg/d; *max:* 90 mg/d	For angina pectoris. Closely monitor blood pressure, especially if patient taking nitrates or beta blockers. A potent calcium channel blocker. Pregnancy category: C; PB: 92%-98%; t½: 2-5 h
nisoldipine (Sular)	A: PO: ER: Initially 17 mg/d; maint: 17-34 mg/d Older adults: PO: Initially 8.5 mg/d; maint: 8.5-34 mg/d	For angina pectoris and hypertension. Suppresses contraction of cardiac and vascular smooth muscle. Increases heart rate and cardiac output. Decreases blood pressure. Caution: Patients with heart disease are prone to MI and HF. Pregnancy category: C; PB: 99%; t½: 7-12 h
verapamil HCl (Calan, Isoptin)	A: PO: 40-120 mg t.i.d.; *max:* 480 mg/d IV: 5-10 mg over 2 min; may repeat in 30 min if needed	For angina pectoris, cardiac dysrhythmias, and hypertension. Peripheral edema, constipation, dizziness, headache, and hypotension may occur. Pregnancy category: C; PB: 90%; t½: 3-8 h

A, Adult; *a.c.,* before meals; *b.i.d.,* twice a day; *CR,* controlled-release; *d,* day; *ER,* extended-release; *h,* hour; *h.s.,* at bedtime; *HF,* heart failure; *IR,* immediate-release; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *MI,* myocardial infarction; *min,* minute; *O$_2$,* oxygen; *PB,* protein-binding; *PO,* by mouth; *PRN,* as necessary; *q.i.d.,* four times a day; *SL,* sublingual; *SR,* sustained-release; *t.i.d.,* three times a day; *t½,* half-life; *UK,* unknown; *>,* greater than.

Pharmacokinetics Beta blockers are well absorbed orally. Absorption of sustained-release capsules is slow. The half-life of propranolol (Inderal) is 3 to 6 hours. Of the selective beta blockers, atenolol (Tenormin) has a half-life of 6 to 7 hours, and metoprolol (Lopressor) has a half-life of 3 to 7 hours. Propranolol and metoprolol are metabolized and excreted by the liver. Half an *oral* dose of atenolol is absorbed from the GI tract, with the remainder excreted unchanged in feces. When given IV, 85% of a dose is excreted in urine within 24 hours.

Pharmacodynamics Because beta blockers decrease the force of myocardial contraction, oxygen demand by the myocardium is reduced. Therefore, the patient can tolerate increased exercise with less oxygen requirement. Beta blockers are effective for classic (stable) angina.

The onset of action of the nonselective beta blocker propranolol is 30 minutes, its peak action is reached in 1 to 1.5 hours, and its duration is 4 to 12 hours. For the cardioselective beta blockers, the onset of action of atenolol is 60 minutes, its peak action occurs in 2 to 4 hours, and its duration of action is 24 hours. The onset of action of selective metoprolol is reached in 15 minutes, and the duration of action is 6 to 12 hours.

Side Effects and Adverse Reactions. Both nonselective and selective beta blockers cause a decrease in heart rate and blood pressure. For the nonselective beta blockers, bronchospasm, behavioral or psychotic response, and impotence (with use of Inderal) are potential adverse reactions.

Vital signs need to be closely monitored in the early stages of beta blocker therapy. When discontinuing use, the dosage should be tapered for 1 or 2 weeks to prevent a rebound effect such as reflex tachycardia or life-threatening cardiac dysrhythmias.

Calcium Channel Blockers

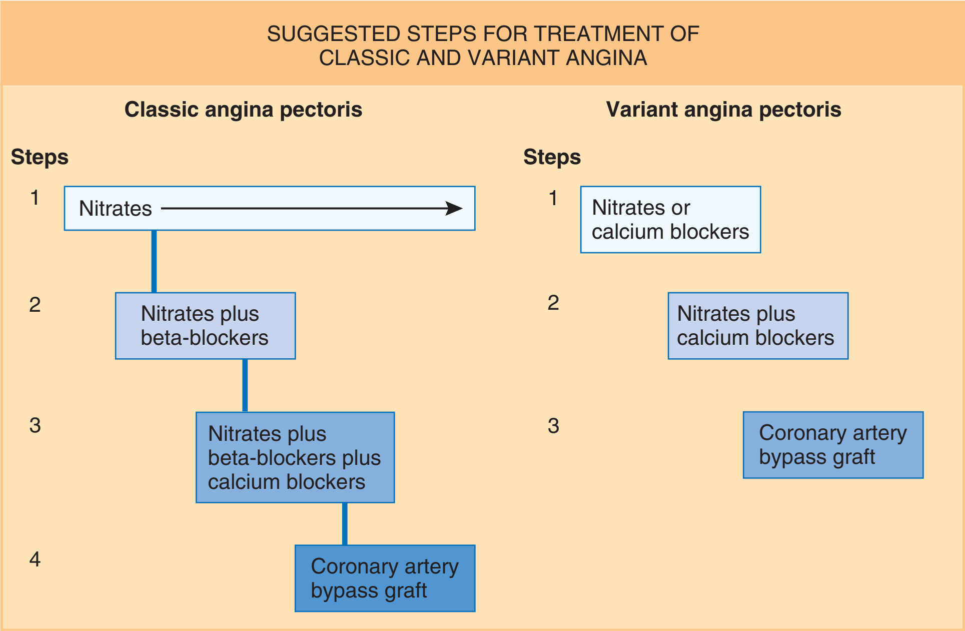
Calcium channel blockers (CCBs), or *calcium blockers,* were introduced in 1982 for the treatment of stable and variant angina pectoris, certain dysrhythmias, and hypertension. Calcium activates myocardial contraction, increasing the workload of the heart and the need for more oxygen. CCBs relax coronary artery spasm (variant angina) and relax peripheral arterioles (stable angina), decreasing cardiac oxygen demand. They also decrease cardiac contractility (negative inotropic effect that relaxes smooth muscle), decrease afterload, decrease peripheral resistance, and reduce the workload of the heart, which decreases the need for oxygen. CCBs achieve their effect in controlling variant (vasospastic) angina by relaxing coronary arteries and in controlling classic (stable) angina by decreasing oxygen demand. Figure 42-1 shows the suggested steps for treating classic and variant angina pectoris. Table 42-4 presents the drug data for the CCBs used to treat angina and their dosages, uses, and considerations.

Pharmacokinetics Three calcium channel blockers—verapamil (Calan), nifedipine (Procardia), and diltiazem (Cardizem)—have been effectively used for the long-term treatment of angina. Eighty to ninety percent of CCBs are absorbed through the GI mucosa. However, first-pass metabolism by the liver decreases the availability of free circulating drug, and only 20% of verapamil, 45% to 65% of diltiazem, and 35% to 40% of nifedipine are bioavailable. All three drugs are highly protein-bound (80% to 90%), and their half-lives are 2 to 9 hours.

Several other CCBs are available, such as nicardipine HCl (Cardene SR), amlodipine (Norvasc), felodipine (Felendil XL), and nisoldipine (Sular). All are highly protein-bound (greater than 95%). Nicardipine has the shortest half-life at 5 hours.

Pharmacodynamics Bradycardia is a common problem with the use of verapamil, the first calcium blocker. Nifedipine, the most potent of the calcium blockers, promotes vasodilation of the coronary and peripheral vessels, and hypotension can result. The onset of action is 10 minutes for verapamil and 30 minutes for nifedipine and diltiazem. Verapamil's duration of action is 3 to 7 hours when given orally and 2 hours when given IV. The duration of action for nifedipine and diltiazem is 6 to 8 hours.

Side Effects and Adverse Reactions. The side effects of calcium blockers include headache, hypotension (more common with nifedipine and less common with diltiazem), dizziness, and flushing of the skin. Reflex tachycardia can occur as a result of hypotension. Peripheral edema may occur with several CCBs including nicardipine, nifedipine, and



SUGGESTED STEPS FOR TREATMENT OF CLASSIC AND VARIANT ANGINA
Classic angina pectoris
Variant angina pectoris
Steps
1
Nitrates
2
Nitrates plus beta-blockers
3
Nitrates plus beta-blockers plus calcium blockers
4
Coronary artery bypass graft
Steps
1
Nitrates or calcium blockers
2

3
Coronary artery bypass graft

FIGURE 42–1 Suggested steps for treating classic and variant angina pectoris.

verapamil. CCBs can cause changes in liver and kidney function. Serum liver enzymes should be checked periodically. CCBs are frequently given with other antianginal drugs such as nitrates to prevent angina.

Nifedipine, in its immediate-release form (10- and 20-mg capsules), has been associated with an increased incidence of sudden cardiac death, especially when prescribed in high doses for outpatients. This is not true of the sustained-release preparations (Procardia XL, Adalat CC). For this reason, immediate-release nifedipine is usually prescribed only as needed in the hospital setting for acute increase in blood pressure.

Nursing Process
Patient-Centered Collaborative Care

Antianginals

Assessment
- Obtain baseline vital signs for future comparisons.
- Obtain health and drug histories. Nitroglycerin is contraindicated for marked hypotension or acute myocardial infarction (AMI).

Nursing Diagnoses
- Decreased cardiac output related to poor myocardial perfusion
- Anxiety related to perceived threat of death
- Acute pain related to anginal pain due to inadequate coronary perfusion and lack of oxygen
- Activity intolerance related to lack of oxygen due to poor blood perfusion to heart and lungs

Planning
- Patient's angina pain will be controlled by nitroglycerin or other antianginals.

Nursing Interventions
- Monitor vital signs. Hypotension is associated with most antianginal drugs.
- Position patient sitting or lying down when taking a nitrate for the first time. After administration, check vital signs while patient is lying down and then sitting up. Have patient rise slowly to standing position.
- Offer sips of water before giving sublingual (SL) nitrates; dryness may inhibit drug absorption.
- Monitor effects of IV nitroglycerin. Report angina that persists.
- Apply Nitro-Bid ointment to designated mark on paper. Do *not* use fingers because drug can be absorbed; use tongue blade or gloves. For Transderm-Nitro patch, do not touch medication portion.
- Do *not* apply Nitro-Bid ointment or Transderm-Nitro patch in any area on the chest in the vicinity of defibrillator-cardioverter paddle placement. Explosion and skin burns may result.

Patient Teaching
General
- Administer SL nitroglycerin tablet if chest pain occurs. If pain has not subsided or has worsened in 5 minutes, call 911.
- Advise patient not to ingest alcohol while taking nitroglycerin to avoid hypotension, weakness, and faintness.
- Advise patient to notify health care provider if chest pain is not completely alleviated. Tolerance to nitroglycerin can occur.
- Inform patient not to discontinue beta blockers and calcium blockers without health care provider's approval. Withdrawal symptoms (reflex tachycardia and pain) may be severe.

Self-Administration
- Demonstrate how (SL) nitroglycerin tablets are taken. Tablet is placed under tongue for quick absorption. Stinging or biting sensation indicates that tablet is fresh; however, with newer SL nitroglycerin tablets, biting sensation may not be present.
- Teach patient to store medication bottle away from light and to keep it dry. Keep drug in original screw-cap, amber glass bottle. Amber color of glass provides light protection, and screw-cap closure protects from moisture in the air, which can easily reduce potency of tablets.
- Teach patient about Transderm-Nitro patch. Apply once a day, usually in morning. Rotate skin sites. Patch is usually applied to chest wall, but thighs and arms may also be used. Avoid hairy areas.
- Advise patient to seek medical attention if nitroglycerin does not relieve pain.

Side Effects
- Suggest acetaminophen (Tylenol) to patient for relief of headache, which commonly occurs when first taking nitroglycerin products and lasts about 30 minutes.
- Place patient in supine position with legs elevated if hypotension results from SL nitroglycerin.
- Instruct patient how to take pulse rate.
- Advise patient taking beta blockers and calcium blockers to notify health care provider if dizziness or faintness occurs, as this may indicate hypotension.

Cultural Considerations
- Address cultural issues directly, especially in matters concerning dietary contributors to cardiac conditions. Family and community are important resources for promoting adherence to medication regimens and lifestyle changes.
- Provide printed materials in language that patient speaks and reads most easily. An interpreter may be necessary to establish sound, trusting relationship and ensure compliance with drug and diet regimens.

Evaluation

- Evaluate patient's response to nitrate product for relieving anginal pain. Note headache, dizziness, or faintness.

ANTIDYSRHYTHMIC DRUGS

Cardiac Dysrhythmias

A **cardiac dysrhythmia (arrhythmia)** is defined as any deviation from the normal rate or pattern of the heartbeat. This includes heart rates that are too slow (bradycardia), too fast **(tachycardia),** or irregular. The terms *dysrhythmia* (disturbed heart rhythm) and *arrhythmia* (absence of heart rhythm) are used interchangeably, despite the slight difference in meaning.

The ECG identifies the type of dysrhythmia. The P wave of the ECG reflects atrial activation, the QRS complex indicates ventricular depolarization, and the T wave reflects ventricular **repolarization** (return of cell membrane potential to resting after depolarization). The P-R interval indicates AV conduction time, and the Q-T interval reflects ventricular action potential duration. Atrial dysrhythmias prevent proper filling of the ventricles and decrease cardiac output by 33%. Ventricular dysrhythmias are life-threatening because ineffective filling of the ventricle and ineffective pumping results in decreased or absent cardiac output. With ventricular tachycardia, ventricular fibrillation is likely to occur, followed by death. Cardiopulmonary resuscitation (CPR) is necessary to treat these patients.

Cardiac dysrhythmias frequently follow an MI (heart attack) or can result from **hypoxia** (lack of oxygen to body tissues), **hypercapnia** (increased carbon dioxide in the blood), thyroid disease, coronary artery disease, cardiac surgery, excess catecholamines, or electrolyte imbalance.

Cardiac Action Potentials

Electrolyte transfer occurs through the cardiac muscle cell membrane. When sodium and calcium enter the cardiac cell, **depolarization** (myocardial contraction) occurs. Sodium enters rapidly to start the depolarization, and calcium enters later to maintain it. Calcium influx leads to an increased release of intracellular calcium from the sarcoplasmic reticulum, resulting in cardiac contraction. In the presence of myocardial ischemia, the contraction can be irregular.

Cardiac action potentials are transient depolarizations followed by repolarizations of myocardial cells. Figure 42-2 illustrates the action potential of a ventricular cardiac cell (myocyte) during the course of a heartbeat. There are five phases. Phase 0 is the rapid depolarization caused by an influx of sodium ions. Phase 1 is initial repolarization, which coincides with termination of sodium ion influx. Phase 2 is the plateau and is characterized by the influx of calcium ions, which prolong the action potential and promote atrial and ventricular muscle contraction. Phase 3 is rapid repolarization caused by influx of potassium ions. Phase 4 is the resting membrane potential between heartbeats. It is normally flat in ventricular muscle, but it begins to rise in the cells of the sinoatrial (SA) node as they slowly depolarize toward the threshold potential just before depolarization occurs, initiating the next heartbeat.

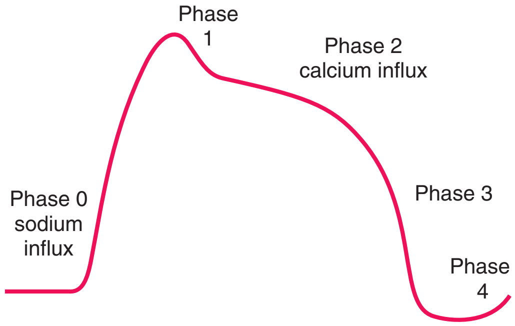

FIGURE 42–2 Action potential of a ventricular myocyte during the course of a heartbeat.

BOX 42-1 PHARMACODYNAMICS OF ANTIDYSRHYTHMICS

Mechanisms of Action

- Block adrenergic stimulation of the heart
- Depress myocardial excitability and contractility
- Decrease conduction velocity in cardiac tissue
- Increase recovery time (repolarization) of the myocardium
- Suppress automaticity (spontaneous depolarization to initiate beats)

Types of Antidysrhythmic Drugs

The desired action of **antidysrhythmic (antiarrhythmic) drugs** is to restore the cardiac rhythm to normal. Box 42-1 describes the various mechanisms by which this is accomplished.

The antidysrhythmics are grouped into four classes: (1) sodium (fast) channel blockers IA, IB, and IC; (2) beta blockers; (3) drugs that prolong repolarization; and (4) calcium (slow) channel blockers. Table 42-5 lists the classes, actions, and indications for cardiac antidysrhythmic drugs. Table 42-6 lists the commonly administered antidysrhythmics and their dosages, uses, and considerations.

Class I: Sodium Channel Blockers

A sodium channel blocker decreases sodium influx into cardiac cells. Responses to the drug are decreased conduction velocity in cardiac tissues; suppression of automaticity, which decreases the likelihood of ectopic foci; and increased recovery time (repolarization or refractory period). There are three subgroups of sodium channel blockers. Class IA slows conduction and prolongs repolarization (quinidine, procainamide, disopyramide). Class IB slows conduction and shortens repolarization (lidocaine, mexiletine HCl). Class IC prolongs conduction with little to no effect on repolarization (flecainide).

Lidocaine, a Class IB sodium channel blocker, was used in the 1940s as a local anesthetic and is still used for this purpose. It was later discovered to have antidysrhythmic properties as

TABLE 42-5 CLASSES, ACTIONS, AND INDICATIONS OF ANTIDYSRHYTHMIC DRUGS

CLASSES	ACTIONS	INDICATIONS
Class I ***Sodium Channel Blockers***		
IA	Slow conduction and prolong repolarization	Atrial and ventricular dysrhythmias, paroxysmal atrial tachycardia (PAT), supraventricular dysrhythmias
IB	Slow conduction and shorten repolarization	Acute ventricular dysrhythmias
IC	Prolong conduction with little to no effect on repolarization	Life-threatening ventricular dysrhythmias
Class II		
Beta blockers	Reduce calcium entry Decrease conduction velocity, automaticity, and recovery time (refractory period)	Atrial flutter and fibrillation, tachydysrhythmias, ventricular and supraventricular dysrhythmias
Class III		
Drugs that prolong repolarization	Prolong repolarization during ventricular dysrhythmias Prolong action potential duration	Life-threatening atrial and ventricular dysrhythmias resistant to other drugs
Class IV		
Calcium channel blockers	Block calcium influx Slow conduction velocity Decrease myocardial contractility (negative inotropic) Increase refraction in AV node	Supraventricular tachydysrhythmias; prevention of PSVT

AV, Atrioventricular, *PVST,* paroxysmal supraventricular tachycardia.

TABLE 42-6 ANTIDYSRHYTHMICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Class I ***Sodium Channel Blockers IA***		
disopyramide phosphate (Norpace)	A: PO: 100-200 mg q6h; *max:* 800 mg/d C: 4-12 y: PO: 10-15 mg/kg/d in divided doses A: PO: ER: 200-300 mg q12h; *max:* 800 mg/d	Prevention and suppression of unifocal and multifocal premature ventricular contractions (PVCs). For ventricular dysrhythmias. May cause anticholinergic symptoms. Serum therapeutic level is 3-8 mcg/mL. Pregnancy category: C; PB: 90%; t½: 4-10 h
procainamide HCl	A: PO: LD: 1000-1250 mg q3-4h A: IM: 50 mg/kg/d in 4 divided doses A: IV: LD: 20-50 mg/min; maint: 1-4 mg/min continuous inf C: IV: LD: 15 mg/kg over 30-60 min TDM: 4-10 mcg/mL	Controls dysrhythmias (PVCs) and ventricular tachycardia. Depresses myocardial excitability by slowing down conductivity of cardiac tissue. Pregnancy category: C; PB: 15%, t½: 3-4 h
quinidine sulfate,	A: PO: 200-300 mg t.i.d./q.i.d. A: PO: ER: 300-600 mg q8-12h TDM: 2-6 mcg/mL	For atrial, ventricular, and supraventricular dysrhythmias. Nausea, vomiting, diarrhea, and abdominal pain or cramps are common side effects. If given with digoxin, can increase digoxin concentration. Pregnancy category: C; PB: 80%-90%; t½: 6-7 h
Sodium Channel Blockers IB		
lidocaine (Xylocaine)	A: IV: 50-100 mg bolus in 2-3 min; *max LD:* 300 mg over 1 h, then IV inf: 20-50 mcg/kg/min TDM: 1.5-6 mcg/mL	For acute ventricular dysrhythmias following MI and cardiac surgery. Pregnancy category: B; PB: 60%-80%; t½: 1.5-2 h
mexiletine HCl	A: PO: 200-300 mg q8h; *max:* 1200 mg/d TDM: 0.5-2 mcg/mL	Analogue of lidocaine. Treatment for acute and chronic ventricular dysrhythmias. Take with food to decrease GI distress. Common side effects are nausea, vomiting, heartburn, tremor, dizziness, nervousness, lightheadedness. Pregnancy category: C; PB: 50%-60%; t½: 10-12 h

TABLE 42-6 **ANTIDYSRHYTHMICS—cont'd**

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Sodium Channel Blockers IC		
flecainide (Tambocor)	A: PO: Initial: 50-100 mg q12h; Increase by 50 mg q12h q4d; maint: 150 mg q12h; *max:* 400 mg/d	For life-threatening ventricular dysrhythmias and prevention of PSVT and PAF. Contraindicated in cardiogenic shock, second- or third-degree heart block, or right bundle branch block. Pregnancy category: C; PB: 40%-50%; $t_{1/2}$: 12-30 h
propafenone HCl (Rythmol)	A: PO: 150-300 mg q8h; *max:* 900 mg/d A: PO: ER: 225-325 mg q12h; *max:* 850 mg/d	For life-threatening ventricular dysrhythmias. Contraindicated if cardiogenic shock, uncontrolled HF, heart block, severe hypotension, bradycardia, or bronchospasm present. Pregnancy category: C; PB: 85%-97%; $t_{1/2}$: 5-8 h
Class II		
Beta-Adrenergic Blockers		
acebutolol HCl (Sectral) (beta$_1$ blocker)	See Prototype Drug Chart 42-3.	
esmolol (Brevibloc) (beta$_1$ blocker)	A: IV: LD: 500 mcg/kg over 1 min; maint: 50-100 mcg/kg/min; *max:* 200 mcg/kg/min	To control atrial flutter and fibrillation. For short-term use only. Mainly for patients having dysrhythmias during surgery. May cause bradycardia, heart block, and HF. Pregnancy category: C; PB: 55%; $t_{1/2}$: 9 min
propranolol HCl (Inderal, Inderal LA) (beta$_1$ and beta$_2$ blocker)	A: PO: 10-30 mg t.i.d./q.i.d. ER: 80 mg/d A: IV bolus: 0.5-3 mg at 1 mg/min	For ventricular dysrhythmias, PAT, and atrial and ventricular ectopic beats. Contraindicated for patients with asthma. Pregnancy category: C; PB: 90%; $t_{1/2}$: 2-6 h
sotalol HCl (Betapace) (beta$_1$ and beta$_2$ blocker; also Class III)	A: PO: 80 mg b.i.d.; *max:* 240-320 mg/d in divided doses Increase dose interval with renal dysfunction	For sustained ventricular dysrhythmias. Contraindicated if bronchial asthma or heart block present. Correct hypokalemia and hypomagnesemia prior to initiating sotalol. Pregnancy category: B; PB: 0%; $t_{1/2}$: 12 h
Class III		
Drugs That Prolong Repolarization		
adenosine (Adenocard)	A: IV: Initially, 6 mg rapid IV bolus (1-2 sec) Repeat if necessary: 12 mg rapid IV bolus × 2 doses	Treatment of PSVT, Wolff-Parkinson-White syndrome. Contraindicated if second- or third-degree AV block or atrial flutter or fibrillation present. Pregnancy category: C; PB: UK; $t_{1/2}$: <10 sec
amiodarone HCl (Cordarone)	A: PO: LD: 400-1600 mg/d in divided doses; maint: 200-600 mg/d; dose may be individualized TDM: 1-2.5 mcg/mL	For life-threatening ventricular dysrhythmias. Initially dosage is greater, and then it decreases over time. Pregnancy category: D; PB: >99%; $t_{1/2}$: 7-50 d
dofetilide (Tikosyn)	PO: 250-1000 mcg/d in 2 divided doses Dose usually individualized based on calculated creatinine clearance	Selective potassium channel blocker that prolongs repolarization. Prescribed for atrial flutter and fibrillation. Monitor renal function. Pregnancy category: C; PB: 60%-70%; $t_{1/2}$: 10 h
ibutilide (Corvert)	A: >60 kg: IV: 0.1 mg/kg or 1 mg (1 vial) over 10 min; may repeat in 10 min. A: <60 kg: IV: 0.01 mg/kg given over 10 min	Prolongs action potential and increases atrial and ventricular refractories; prolongs Q-T interval. May be given to convert atrial flutter and fibrillation to normal sinus rhythm. Pregnancy category: C; PB: 40%; $t_{1/2}$: 2-12 h
sotalol (Betapace)	A: PO: Same as Class II (see sotalol in Class II)	Beta blocker. Can be classified as Class II or III. To treat life-threatening ventricular dysrhythmias (ventricular tachycardia). Slows heart rate, decreases AV conduction, increases AV refractory period, and decreases systolic and diastolic BP. Caution: Contraindicated if second- and third-degree heart block present. (See sotalol in Class II.)
Class IV		
Calcium Channel Blockers		
verapamil HCl (Calan, Isoptin)	A: PO: 240-480 mg/d in 3-4 divided doses A: IV: 2.5-10 mg IV push over 2 min; may repeat in 30 min	For supraventricular tachydysrhythmias, prevention of PSVT, angina pectoris, and hypertension. Contraindicated if cardiogenic shock, second- or third-degree AV block, severe hypotension, or severe HF present. Serum therapeutic level: 80-300 ng/mL or 0.08-0.3 mcg/mL. Pregnancy category: C; PB: 90%; $t_{1/2}$: 3-8 h
diltiazem (Cardizem)	A: IV: 0.25 mg/kg IV bolus over 2 min, or 5-10 mg/h in IV inf	For PSVT and atrial flutter or fibrillation. Contraindicated if second- or third-degree AV block or hypotension present. Pregnancy category: C; PB: 70%-80%; $t_{1/2}$: 3-8 h

Continued

TABLE 42-6 ANTIDYSRHYTHMICS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Others		
digoxin (Lanoxin)	A: PO: LD: 10-15 mcg/kg q6-8h given in 3 divided doses A/C: >10 y: IV: LD: 8-12 mcg/kg Maintenance: 0.125-0.5 mg/d	For atrial flutter or fibrillation; to prevent recurrence of paroxysmal atrial tachycardia. Pregnancy category: C; PB: 30%; $t\frac{1}{2}$: >36 h
dronedarone (Multaq)	A: PO: 400 mg b.i.d. with morning and evening meal	For atrial fibrillation and atrial flutter. Has antidysrhythmic properties of all four classes. May lead to photosensitivity and severe diarrhea. Contraindicated if severe heart failure present. Avoid grapefruit and grapefruit juice. Pregnancy category: X; PB: 98%; $t\frac{1}{2}$: 13-19 h

A, Adult; *AV,* atrioventricular; *b.i.d.,* two times a day; *BP,* blood pressure; *C,* child; *CR,* controlled-release; *d,* day; *ER,* extended-release; *FDA,* U.S. Food and Drug Administration; *h,* hour; *HF,* heart failure; *GI,* gastrointestinal; *IM,* intramuscular; *inf,* infusion; *IV,* intravenous; *LD,* loading dose; *maint,* maintenance; *max,* maximum; *MI,* myocardial infarction; *min,* minute; *PAT,* paroxysmal atrial tachycardia; *PAF,* paroxysmal atrial fibrillation (or flutter); *PVST,* paroxysmal supraventricular tachycardia; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *SR,* sustained-release; *TDM,* therapeutic drug monitoring; *$t\frac{1}{2}$,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *y,* year; *>,* greater than; *<,* less than.

well. Lidocaine is still used by some cardiologists to treat acute ventricular dysrhythmias. It slows conduction velocity and decreases action potential amplitude. Onset of action (IV) is rapid. About one third of lidocaine reaches the general circulation. A bolus of lidocaine is short-lived. Another Class IB sodium channel blocker is mexiletine.

Class II: Beta Blockers

The drugs in the second class, beta blockers, decrease conduction velocity, automaticity, and recovery time (refractory period). Examples are propranolol (Inderal), acebutolol (Sectral), esmolol (Brevibloc), and sotalol (Betapace). Beta blockers are more frequently prescribed for dysrhythmias than sodium channel blockers. Prototype Drug Chart 42-3 lists the drug data related to the beta blocker acebutolol HCL (Sectral), which can be prescribed to treat recurrent stable ventricular dysrhythmias.

Pharmacokinetics The cardioselective beta drug acebutolol (Sectral) is well absorbed in the GI tract. It is metabolized in the liver to active metabolites; 50% to 60% of the drug is eliminated in the bile via feces, and 30% to 40% is excreted in the urine. The half-life for the drug is 3 to 4 hours, but the half-life for its metabolites is 8 to 13 hours.

Pharmacodynamics Acebutolol is prescribed for ventricular dysrhythmias as well as for angina pectoris and hypertension. As an antidysrhythmic drug, the onset of action is 1 hour; peak time is 4 to 6 hours, and duration of action is 10 hours. To treat hypertension, the duration of action is 20 to 24 hours.

Class III: Drugs That Prolong Repolarization

Drugs in the third class prolong repolarization and are used in emergency treatment of ventricular dysrhythmias when other antidysrhythmics are ineffective. Amiodarone (Cordarone) increases the refractory period (recovery time) and prolongs the action potential duration (cardiac cell activity).

Class IV: Calcium Channel Blockers

The fourth class consists of the calcium channel blockers verapamil (Calan, Isoptin) and diltiazem (Cardizem). Verapamil is a slow (calcium) channel blocker that blocks calcium influx, thereby decreasing the excitability and contractility (negative inotropic) of the myocardium. It increases the refractory period of the AV node, which decreases ventricular response. Verapamil is contraindicated for patients with AV block or HF.

Side Effects and Adverse Reactions for Antidysrhythmic Drugs. Quinidine, the first drug used to treat cardiac dysrhythmias, has many side effects (e.g., nausea, vomiting, diarrhea, confusion, hypotension). It can also cause heart block and neurologic and psychiatric symptoms. Procainamide causes less cardiac depression than quinidine.

High doses of lidocaine can cause cardiovascular depression, bradycardia, hypotension, seizures, blurred vision, and double vision. Less serious side effects may include dizziness, lightheadedness, and confusion. The use of lidocaine is contraindicated in patients with advanced AV block. It should also be used with caution in patients with liver disorder and HF. Mexiletine and tocainide have side effects similar to lidocaine. They are contraindicated for use in patients with cardiogenic shock or in those with second- or third-degree heart block.

Side effects of beta blockers are bradycardia and hypotension. Bretylium and amiodarone can cause nausea, vomiting, hypotension, and neurologic problems. Side effects of calcium blockers include nausea, vomiting, hypotension, and bradycardia.

It should be noted that *all* antidysrhythmic drugs are potentially prodysrhythmic. This is because of both the pharmacologic activity of the drug on the heart and the inherently unpredictable activity of a diseased heart, with or without the use of drugs. In some cases, life-threatening ventricular dysrhythmias can result from appropriate and skillful attempts at drug therapy to treat patients with heart disease. For these reasons, antidysrhythmic drug therapy is often initiated during continuous cardiac monitoring of the patient's heart rhythm in a hospital setting.

PROTOTYPE DRUG CHART 42-3

Acebutolol HCl

Drug Class

Beta$_1$ blocker: cardioselective beta-adrenergic antagonist
Trade Names: Sectral
Pregnancy Category: B

Dosage

Ventricular dysrhythmia:
A: PO: 200 mg q12h
May increase to 600-1200 mg in 2 divided doses; *max:* 1200 mg/d
Older adults: PO: 200-400 mg/d; *max:* 800 mg/d
Not for children <12 y

Contraindications

Second- and third-degree heart block, severe bradycardia, severe HF, cardiogenic shock
Caution: Undergoing major surgery, renal and hepatic impairment, diabetes mellitus, hyperthyroidism, asthma, bronchitis, COPD

Drug-Lab-Food Interactions

Drug: Increase effects with diuretics; prolong hypoglycemic effects of insulin and oral antidiabetics; antagonist effect with albuterol, metaproterenol, terbutaline.
Lab: May increase ALT, AST, ALP, ANA titer, BUN, lipoproteins, potassium.

Pharmacokinetics

Absorption: Well absorbed
Distribution:
PB: 26%
Metabolism: t½: 3-4 h; metabolites: 8-13 h
Excretion: 90%-100% in bile, feces, and urine

Pharmacodynamics

Ventricular dysrhythmias:
PO: Onset: 1 h
Peak: 2.5-3.5 h
Duration: 10 h

Therapeutic Effects/Uses

To aid in treatment of recurrent stable ventricular dysrhythmias, angina pectoris, and hypertension.
Mode of Action: Blocks beta$_1$-adrenergic receptors in cardiac tissues.

Side Effects

Dizziness, nausea, vomiting, anorexia, edema, headache, visual impairment, hypotension, diaphoresis, fatigue, insomnia, constipation, diarrhea, impotence

Adverse Reactions

Palpitations with abrupt withdrawal, bradycardia, chest pain, hyperglycemia, hypoglycemia, diabetes mellitus
Life-threatening: agranulocytosis, bronchospasm (high doses)

A, Adult; *ALP,* alkaline phosphatase; *ALT,* alanine aminotransferase; *ANA,* antinuclear antibodies; *AST,* aspartate aminotransferase; *b.i.d.,* twice a day; *BUN,* blood urea nitrogen; *h,* hour; *HF,* heart failure; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *<,* less than.

Nursing Process

Patient-Centered Collaborative Care

Antidysrhythmics

Assessment

- Obtain health and drug histories. History may include shortness of breath, heart palpitations, coughing, chest pain (type, duration, and severity), previous angina or cardiac dysrhythmias, and drugs patient currently takes.
- Obtain baseline vital signs and electrocardiogram (ECG) for future comparison.
- Monitor early cardiac enzyme results (aspartate aminotransferase, lactate dehydrogenase, creatine phosphokinase) and troponins (cardiac-specific) for future comparison.

Nursing Diagnoses

- Decreased cardiac output related to cardiac dysrhythmia
- Anxiety related to irregular heartbeat
- Risk for activity intolerance related to lack of oxygen due to irregular heart rate

Planning

- Patient will no longer experience abnormal sinus rhythm.
- Patient will comply with antidysrhythmic drug regimen.

Nursing Interventions

- Monitor vital signs because hypotension can occur.
- Administer drug by IV push or bolus over a period of 2 to 3 minutes or as prescribed.
- Monitor ECG for abnormal patterns, and report findings such as premature ventricular contractions (PVCs), increased P-R and Q-T intervals, and/or widening of QRS complex. Increased Q-T interval is a risk factor for *torsades de pointes*.

Patient Teaching

General

- Teach patient to take prescribed drug as ordered because drug compliance is essential.

- Provide specific instructions for each drug (e.g., photosensitivity for amiodarone).

Side Effects

- Tell patient to report side effects and adverse reactions to health care provider, including dizziness, faintness, nausea, and vomiting.
- Advise patient to avoid alcohol, caffeine, and tobacco. Alcohol can intensify hypotensive reaction; caffeine increases catecholamine level; and tobacco promotes vasoconstriction.

Cultural Considerations

- Advise patient to focus on relationship between certain dietary habits and cardiac disease. Discuss importance of drug regimen in terms that directly address cultural issues and accommodate family's values. An interpreter may be necessary to ensure patient's understanding and compliance with drug and dietary regimens.

Evaluation

- Evaluate effectiveness of prescribed antidysrhythmic by comparing heart rates with baseline heart rate and assessing patient's response to drug.
- Report side effects and adverse reactions. Drug regimen may need to be adjusted. Proarrhythmic effect may occur, which may require discontinuation of drug.

American College of Cardiology: *www.acc.org*

CRITICAL THINKING CASE STUDY

ST, a 64-year-old patient, has heart failure (HF), which is being controlled with digoxin (Lanoxin), furosemide (Lasix), and a low-sodium diet. She is taking potassium chloride (KCl) 20 mEq per day orally. Three days ago, ST had flulike symptoms such as anorexia, lethargy, and diarrhea. Her fluid and food intake was diminished. She refused to take the KCl and stated that the drug makes her sick. She has been taking the digoxin and furosemide daily.

The nurse's assessment during the home visit includes poor skin turgor, poor muscle tone, irregular pulse rate, and decreased bowel sounds. The nurse obtained a blood sample for serum electrolytes; results indicated potassium (K) 2.9 mEq/L, sodium (Na) 137 mEq/L, and chloride (Cl) 96 mEq/L.

1. List reference values for serum potassium (K), serum sodium (Na), and serum chloride (Cl). Are ST's electrolyte levels within normal range? Explain your answer.
2. Match ST's physical findings with the corresponding electrolyte imbalance.
3. What are the reasons for the electrolyte imbalance?
4. ST said she was not taking KCl because the drug makes her sick. What information can you give her concerning the administration of potassium?
5. What is the effect of furosemide on digoxin when there is a potassium deficit? Explain your answer.
6. Why should the nurse assess ST for digitalis toxicity? List the signs and symptoms of digitalis toxicity.

ST was referred to the health care provider because of her serum potassium deficit and its effect on digoxin. A repeat serum potassium determination was taken, and the result was 2.8 mEq/L. A liter of 5% dextrose in water with KCl 40 mEq/L was administered over 4 hours.

7. How many milliequivalents of KCl per hour would ST receive? Does this amount constitute an acceptable dosage?
8. Why is it important that the nurse monitor the rate of intravenous fluids containing potassium, the hourly urine output, and vital signs?
9. Because of the low serum potassium level, what other electrolyte value should be checked? Explain your answer.

After ST's serum electrolytes returned to normal, the health care provider instructed her to continue taking the prescribed KCl dosage daily with her other medications.

10. ST asks why she has to continue taking these drugs. What is the nurse's best response?
11. The nurse instructs ST to eat foods rich in potassium. Which foods are the richest sources of potassium?

NCLEX STUDY QUESTIONS

1. The patient is receiving digoxin for treatment of heart failure. Which finding would suggest to the nurse that heart failure is improving?
   a. Pale and cool extremities
   b. Absence of peripheral edema
   c. Urine output of 60 mL/4 h
   d. Complaints of increasing dyspnea
2. The patient's serum digoxin level is 3.0 ng/mL. What does the nurse know about this serum digoxin level?
   a. It is in the high (elevated) range.
   b. It is in the low (decreased) range.
   c. It is within the normal range.
   d. It is in the low average range.
3. The nurse is assessing a patient for possible evidence of digitalis toxicity. The nurse acknowledges that which is included in the signs and symptoms for digitalis toxicity?
   a. Apical pulse rate of 100 beats/min
   b. Apical pulse of 72 beats/min with an irregular rate
   c. Apical pulse of 90 beats/min and an irregular rate
   d. Apical pulse of 48 beats/min and irregular rate
4. A patient is taking a potassium-depleting diuretic and digoxin. The nurse expects that a low potassium level (hypokalemia) could have what effect on digoxin (Lanoxin)?
   a. Increase serum digoxin sensitivity level
   b. Decrease serum digoxin sensitivity level
   c. Have no effect on serum digoxin sensitivity level
   d. Cause a low average serum digoxin sensitivity level
5. A patient takes an initial dose of a nitrate. Which symptom(s) will the nurse expect to occur?
   a. Nausea and vomiting
   b. Headaches
   c. Stomach cramps
   d. Irregular pulse rate
6. A patient is prescribed a beta blocker. The nurse acknowledges that beta blockers are as effective as antianginals because they do what?
   a. Increase oxygen to the systemic circulation
   b. Maintain heart rate and blood pressure
   c. Decrease heart rate and decrease myocardial contractility
   d. Decrease heart rate and increase myocardial contractility
7. The health care provider is planning to discontinue a patient's beta blocker. Which instruction will the nurse give the patient regarding the beta blocker?
   a. The beta blocker should be abruptly stopped when another cardiac drug is prescribed.
   b. The beta blocker should not be abruptly stopped; the dose should be tapered down.
   c. The beta blocker dose should be maintained while taking another antianginal drug.
   d. Half the beta blocker dose should be taken for the next several weeks.
8. The beta blocker acebutolol (Sectral) is prescribed for dysrhythmias. The nurse knows that what is the primary purpose of the drug?
   a. Increase beta$_1$ and beta$_2$ receptors in cardiac tissues
   b. Increase the flow of oxygen to cardiac tissues
   c. Block beta$_1$-adrenergic receptors in cardiac tissues
   d. Block beta$_2$-adrenergic receptors in cardiac tissues
9. A patient who has angina is prescribed nitroglycerin. Which are appropriate nursing interventions for nitroglycerin? (Select all that apply.)
   a. Have patient sit or lie down when taking a nitroglycerin sublingual tablet.
   b. Teach patient who has taken a tablet to call 911 in 5 minutes if chest pain persists.
   c. Apply Transderm-Nitro patch to a hairy area to protect skin from burning.
   d. Call the health care provider after taking five tablets if chest pain persists.
   e. Warn patient against ingesting alcohol while taking nitroglycerin.

OBJECTIVES

- Compare the action and uses of thiazide, loop, and potassium-sparing diuretics.
- Differentiate side effects and adverse reactions related to thiazide, loop, and potassium-sparing diuretics.
- Explain the nursing interventions, including patient teaching, related to thiazide, loop, and potassium-sparing diuretics.
- Apply the nursing process for the patient taking thiazide, loop, and potassium-sparing diuretics.

Diuretics are used for two main purposes: to decrease hypertension (lower blood pressure) and to decrease edema (peripheral and pulmonary) in heart failure (HF) and renal or liver disorders. **Hypertension** is an elevated blood pressure. Diuretics discussed in this chapter are used either alone or in combination to decrease blood pressure and edema.

Diuretics produce increased urine flow, or **diuresis,** by inhibiting sodium and water reabsorption from the kidney tubules. Most sodium and water reabsorption occurs throughout the renal tubular segments (proximal, loop of Henle [descending loop and ascending loop], and collecting tubule). Diuretics can affect one or more segments of the renal tubules. Figure 43-1 illustrates the renal tubule along with the normal process of water and electrolyte reabsorption and diuretic effects on the tubules.

Every 1.5 hours, the total volume of the body's extracellular fluid (ECF) goes through the kidneys (glomeruli) for cleansing; this is the first process for urine formation. Small

FIGURE 43–1 Diuretics act on different segments of the renal tubule. Osmotic, mercurial, and carbonic anhydrase inhibitor diuretics affect the proximal tubule; loop diuretics affect the loop of Henle; thiazides affect the distal tubule; and potassium-sparing diuretics act primarily on the collecting tubules.

particles such as electrolytes, drugs, glucose, and waste products from protein metabolism are filtered in the glomeruli. Larger products such as protein and blood cells are not filtered with normal renal function, and they remain in the circulation. Sodium and water are the largest filtrate substances.

Normally 99% of the filtered sodium that passes through the glomeruli is reabsorbed; 50% to 55% of sodium reabsorption occurs in the proximal tubules, 35% to 40% in the loop of Henle, 5% to 10% in the distal tubules, and <3% in the collecting tubules. Diuretics that act on the tubules closest to the glomeruli have the greatest effect in causing **natriuresis** (sodium loss in the urine). A classic example is the osmotic diuretic mannitol. The diuretic effect depends on the drug reaching the kidneys and its concentration in the renal tubules.

Diuretics have an **antihypertensive** effect because they promote sodium and water loss by blocking sodium and chloride reabsorption. This causes a decrease in fluid volume, lowering blood pressure. With fluid loss, edema (fluid retention in body tissues) should decrease, but if sodium is retained, water is also retained, and blood pressure increases.

Many diuretics cause the loss of other electrolytes, including potassium, magnesium, chloride, and bicarbonate. The diuretics that promote potassium excretion are classified as **potassium-wasting diuretics,** and those that promote potassium retention are called **potassium-sparing diuretics.**

The following five categories of diuretics are effective in removing water and sodium:

- Thiazide and thiazide-like
- Loop or high-ceiling
- Osmotic
- Carbonic anhydrase inhibitor
- Potassium-sparing

Thiazide, loop, and potassium-sparing diuretics are most frequently prescribed for hypertension and for edema

TABLE 43-1 DIURETICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Thiazides		
Short-Acting		
chlorothiazide (Diuril)	A: PO: 250-1000 mg/d in 1-2 divided doses A: IV: 500-1000 mg/d in 1-2 divided doses C: PO: 10-20 mg/kg/d in 1-2 divided doses	For hypertension and peripheral edema. Adults may be given IV chlorothiazide, but not recommended for infants and children. Pregnancy category: C; PB: 20%-80%; t½: 1-2 h
hydrochlorothiazide (Esidrix, HCTZ)	See Prototype Drug Chart 43-1.	
Intermediate-Acting		
bendroflumethiazide with Nadolol (Corzide)	A: PO: 40 mg nadolol/5 mg bendroflumethiazide; *max:* 80/5	Treatment of hypertension and edema associated with HF and cirrhosis. Has similar effects as prototype drug HCTZ. Hypokalemia, hyperglycemia, and hyperuricemia may occur. Pregnancy category: C; PB: nadolol: 95%; bendroflumethiazide: 95%; t½: nadolol: 10-24 h; bendroflumethiazide: 3 h
Long-Acting		
methyclothiazide	Hypertension/edema: A: PO: 2.5-10 mg/d; *max:* 5 mg/d for hypertension; 10 mg/d for edema	For hypertension and edema associated with HF and renal or liver dysfunction. Side effects and drug interactions similar to those of HCTZ. Long duration of action. Pregnancy category: B; PB: UK; t½: UK
Thiazide-Like Diuretics		
chlorthalidone (Hygroton, Thalitone)	Hypertension: A: PO: 12.5-50 mg/d; 50 mg/d C: PO: 2 mg/kg/d Edema: A: PO: 25-100 mg/d; *max:* 200 mg/d	For hypertension and edema associated with HF and renal or liver dysfunction. Very long duration of action (24-72 h). Pregnancy category: B; PB: 75%; t½: 40-60 h
indapamide	Hypertension/edema: A: PO: 1.25-2.5 mg/d; may increase to 5 mg/d; *max:* 5 mg/d	For hypertension and edema. Long-acting diuretic. May be classified as loop diuretic. Pregnancy category: B; PB: 71%-79%; t½: 14-18 h
metolazone (Zaroxolyn)	Hypertension: A: PO: 2.5-5.0 mg/d C: PO: 0.2-0.4 mg/kg/d in divided doses Edema: A: PO: 5-20 mg/d	For hypertension and edema. Intermediate-acting diuretic. More effective than thiazides in patients with decreased renal function. Pregnancy category: B; PB: 33%; t½: 14 h

A, Adult; *b.i.d.,* twice a day; *C,* child; *d,* day; *h,* hour; *HF,* heart failure; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *mo,* month; *PO,* by mouth; *PB,* protein-binding; *t½,* half-life; *UK,* unknown; *wk,* week; *y,* year; >, greater than; <, less than.

associated with HF. Except for those in the potassium-sparing group, all diuretics are potassium-wasting.

Combination diuretics that contain both potassium-wasting and potassium-sparing drugs have been marketed primarily for the treatment of hypertension. Combinations have an additive effect in reducing blood pressure and are discussed in more detail in the Potassium-Sparing Diuretics section later in this chapter. Chapter 44 takes a closer look at the combinations of antihypertensive agents with hydrochlorothiazide (HCTZ).

THIAZIDES AND THIAZIDE-LIKE DIURETICS

The first thiazide, chlorothiazide (Diuril), was marketed in 1957 and followed a year later by hydrochlorothiazide. There are numerous thiazide and thiazide-like preparations. Thiazides act on the distal convoluted renal tubule, beyond the loop of Henle, to promote sodium, chloride, and water excretion. Thiazides are used to treat hypertension and peripheral edema. They are not effective for immediate diuresis and should not be used to promote fluid loss in patients with severe renal dysfunction. Table 43-1 lists thiazide and thiazide-like diuretics and their dosages, uses, and considerations. Drug dosages for hypertension and edema are similar.

Thiazide diuretics are used primarily for patients with normal renal function. If the patient has a renal disorder and creatinine clearance is less than 30 mL/min, the effectiveness of the thiazide diuretic is greatly decreased. Thiazides cause a loss of sodium, potassium, and magnesium, but they promote calcium reabsorption. **Hypercalcemia** (calcium excess) may result, and the condition can be hazardous to the patient who is digitalized or has cancer that causes hypercalcemia. Thiazides affect glucose tolerance, so hyperglycemia can also occur. Thiazides should be used cautiously in patients with diabetes mellitus. Laboratory test results (e.g., electrolytes, glucose) need to be monitored.

The thiazide drug hydrochlorothiazide has been combined with selected angiotensin-converting enzyme (ACE) inhibitors, beta-blockers, alpha-blockers, angiotensin II blockers, and centrally acting sympatholytics to control hypertension. Prototype Drug Chart 43-1 outlines the pharmacologic data for hydrochlorothiazide.

Pharmacokinetics Thiazides are well absorbed from the gastrointestinal (GI) tract. Hydrochlorothiazide has moderate protein-binding power. The half-life of the thiazide drugs is longer than that of the loop diuretics. For this reason, thiazides should be administered in the morning to avoid nocturia (nighttime urination) and sleep interruption.

Pharmacodynamics Thiazides act directly on arterioles to cause vasodilation, which can lower blood pressure. Other action includes the promotion of sodium chloride and water excretion, resulting in a decrease in vascular fluid volume and a concomitant decrease in cardiac output and blood pressure. The onset of action of hydrochlorothiazide occurs within 2 hours. Peak concentration times are long (3 to 6 hours). Thiazides are divided into three groups, according to their duration of action: short-acting (duration less than 12 hours), intermediate-acting (duration 12 to 24 hours), and long-acting (duration more than 24 hours).

Side Effects and Adverse Reactions. Side effects and adverse reactions of thiazides include electrolyte imbalances (hypokalemia, hypercalcemia, hypomagnesemia, and bicarbonate loss), **hyperglycemia** (elevated blood sugar), **hyperuricemia** (elevated serum uric acid level), and hyperlipidemia (elevated blood lipid level). Signs and symptoms of hypokalemia should be assessed, and serum potassium levels must be closely monitored. Potassium supplements are frequently needed. Serum calcium and uric acid levels should be checked, because thiazides block calcium and uric acid excretion. Thiazides affect the metabolism of carbohydrates, and hyperglycemia can result, especially in patients with high to high-normal blood sugar levels. Thiazides can increase serum cholesterol, low-density lipoprotein, and triglyceride levels. A drug may be ordered to lower blood lipids. Other side effects include dizziness, headache, nausea, vomiting, constipation, urticaria, or hives (rare), and blood dyscrasias (rare). Table 43-2 summarizes the serum chemistry abnormalities that can occur with thiazide use.

Contraindications. Thiazides are contraindicated for use in renal failure. Symptoms of severe kidney impairment or shutdown include **oliguria** (marked decrease in urine output), elevated blood urea nitrogen (BUN), and elevated serum creatinine.

Drug Interactions. Of the numerous thiazide drug interactions, the most serious occurs with digoxin. Thiazides can

PROTOTYPE DRUG CHART 43-1

Hydrochlorothiazide

Drug Class
Thiazide diuretic
Trade Names: HCT, Esidrix
Pregnancy Category: B

Dosage
Hypertension:
A: PO: 12.5-50 mg/d; *max:* 50 mg/d
Edema:
A: PO: 25-100 mg/d in single or divided doses; *max:* 200 mg/d
C: PO: 1-2 mg/kg/d in divided doses
C: <6 mo: PO: 1-3 mg/kg/d in divided doses

Contraindications
Renal failure with anuria, electrolyte depletion
Caution: Hepatic dysfunction, renal dysfunction, diabetes mellitus, gout, systemic lupus erythematosus

Drug-Lab-Food Interactions
Drug: Increase digitalis toxicity with digitalis if hypokalemia is present; increase renal toxicity with aspirin; increase potassium loss with steroids; decrease antidiabetic effect; decrease thiazide absorption and effects with NSAIDs, cholestyramine, and colestipol
Lab: Increase serum calcium, glucose, uric acid; decrease serum potassium, sodium, magnesium

Pharmacokinetics
Absorption: Readily absorbed from GI tract
Distribution: PB: 65%
Metabolism: t½: 6-15 h
Excretion: In urine

Pharmacodynamics
PO: Onset: 2 h
Peak: 4 h
Duration: 6-12 h

Therapeutic Effects/Uses
To increase urine output; to treat hypertension, edema from HF, hepatic cirrhosis, renal dysfunction
Mode of Action: Action is on the renal distal tubules, promoting sodium, potassium, and water excretion and decreasing preload and cardiac output; also decreases edema; acts on arterioles, causing vasodilation, thus decreasing blood pressure

Side Effects
Dizziness, vertigo, weakness, nausea, vomiting, diarrhea, abdominal pain, hyperglycemia, constipation, rash, photosensitivity, blurred vision

Adverse Reactions
Severe dehydration, hypotension, gout
Life-threatening: Severe potassium depletion, marked hypotension, aplastic anemia, hemolytic anemia, thrombocytopenia, agranulocytosis, renal failure

A, Adult; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *HF,* heart failure; *maint,* maintenance; *mo,* month; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life.

TABLE 43-2 SERUM CHEMISTRY ABNORMALITIES ASSOCIATED WITH THIAZIDES

SERUM CHEMISTRY PARAMETER	ABNORMAL RESULTS
Electrolytes, Normal Levels	
Potassium, 3.5-5.3 mEq/L	Hypokalemia (low serum potassium). Potassium is excreted from the distal renal tubule.
Magnesium, 1.8-3.0 mg/dL	Hypomagnesemia (low serum magnesium). Potassium and sodium loss prompt magnesium loss.
Calcium, 4.5-5.5 mEq/L	Hypercalcemia (elevated serum calcium). Thiazides may block calcium excretion.
Chloride, 95-105 mEq/L	Hypochloremia (low serum chloride). Sodium and potassium losses produce chloride loss.
Bicarbonate, 24-28 mEq/L	Minimal bicarbonate loss from proximal tubule.
Uric acid, 2.8-8.0 mg/dL	Hyperuricemia (elevated uric acid). Thiazides can block uric acid excretion.
Blood sugar, 70-110 mg/dL	Hyperglycemia (increased blood sugar). Thiazides increase fasting blood sugar levels and those of prediabetic state.
Blood Lipids	
Cholesterol: <200 mg/dL	Can elevate cholesterol, LDLs, and triglycerides.
LDL: <100 mg/dL	
Triglyceride: 10-190 mg/dL	

LDL, Low-density lipoprotein.

cause **hypokalemia,** which enhances the action of digoxin, and digitalis toxicity can occur. Potassium supplements are frequently prescribed, and serum potassium levels are monitored. Thiazides also induce hypercalcemia, which enhances the action of digoxin, resulting in possible digitalis toxicity. Signs and symptoms of digitalis toxicity (bradycardia, nausea, vomiting, visual changes) should be reported. Thiazides enhance the action of lithium, and lithium toxicity can occur. Thiazides potentiate the action of other antihypertensive drugs, which may be used to advantage in combination drug therapy for hypertension.

LOOP (HIGH CEILING) DIURETICS

The loop, or high-ceiling, diuretics act on the thick ascending loop of Henle to inhibit chloride transport of sodium into the circulation (inhibit passive reabsorption of sodium). Sodium and water are lost, together with potassium, calcium, and magnesium. Loop diuretics can affect blood sugar and increase uric acid levels. Drugs in this group are extremely potent and cause marked depletion of water and electrolytes. This high diuretic potential is the reason they are often called *high-ceiling diuretics* or *potassium-wasting diuretics*. The effects of loop diuretics are dose-related (i.e., increasing the dose increases the effect and response of the drug). More potent than thiazides for promoting diuresis (inhibiting reabsorption of sodium two to three times more effectively), loop diuretics are less effective as antihypertensive agents.

Loop diuretics should not be prescribed if a thiazide could alleviate body fluid excess. If furosemide (Lasix) alone is not effective in removing body fluid, a thiazide may be added, but furosemide should never be combined with another loop diuretic. Furosemide is usually administered as an oral dose in the morning or intravenously when the patient's condition warrants immediate removal of body fluid, for example, in cases of acute heart failure or pulmonary edema.

Nursing Process
Patient-Centered Collaborative Care

Diuretics: Thiazides

Assessment
- Assess vital signs, weight, urine output, and serum chemistry values (electrolytes, glucose, uric acid) for baseline levels.
- Check peripheral extremities for presence of edema. Note pitting edema.
- Obtain a history of drugs and herbal supplements taken daily. Review for drugs and herbals that may cause drug interaction (digoxin, corticosteroids, antidiabetics, ginkgo, licorice).

Nursing Diagnoses
- Risk for deficient fluid volume related to use or overuse of thiazides
- Impaired urinary elimination related to kidney dysfunction
- Excess fluid volume related to body fluid retention

Planning
- Patient's blood pressure will be decreased and/or return to normal value.
- Patient's edema will be decreased.
- Patient's serum chemistry levels will remain within normal ranges.

Nursing Interventions
- Monitor vital signs and serum electrolytes, especially potassium, glucose, uric acid, and cholesterol levels. Report changes. If patient is taking digoxin and hypokalemia occurs, digitalis toxicity frequently results.
- Observe for signs and symptoms of hypokalemia (e.g., muscle weakness, leg cramps, cardiac dysrhythmias).
- Monitor patient's weight daily. Weight gain of 2.2 lb is equivalent to 1 L of body fluids.
- Note urine output to determine fluid loss or retention.

Patient Teaching

General

- Emphasize the need for adherence. Patient may not "feel better" for some time or may not "feel worse" if treatment is missed or discontinued.
- Suggest that patient take hydrochlorothiazide in early morning to avoid sleep disturbance resulting from nocturia.
- Instruct patient to keep drugs out of reach of small children. Request childproof bottle.
- Inform patient that certain herbal products may interact with thiazide diuretics (Herbal Alert 43-1).

Self-Administration

- Instruct patient or family member on how to take blood pressure and record daily results.

Side Effects

- Instruct patient to slowly change positions from lying to standing, because dizziness may occur as a result of orthostatic (postural) hypotension.
- Advise patient who may be prediabetic to have blood sugar checked periodically, because large doses of hydrochlorothiazide increase blood glucose levels.
- Suggest that patient use sunblock when in direct sunlight for photosensitivity

Diet

- Teach patient to eat foods rich in potassium (fruits, fruit juices, and vegetables). Potassium supplements may be ordered.
- Instruct patient to take drugs with food to avoid gastrointestinal upset.

Cultural Considerations

- Respect cultural practices and values. If patient from a different background tells the health care provider that she or he does not eat fruits and vegetables, the nurse may have two options: to encourage patient to eat fruits and vegetables, or to contact health care provider so that an adequate potassium supplement can be prescribed to overcome potassium loss. An interpreter may be necessary.
- Emphasize importance of patient taking potassium supplement with potassium-wasting diuretic. In addition, advise patient of consequences and dangers of not taking potassium supplements or lacking appropriate nutrition while taking potassium-wasting diuretics. Monitor serum potassium levels.

Evaluation

- Evaluate the effectiveness of drug therapy. Patient's blood pressure and edema will be reduced, and blood chemistry will remain within normal range.
- Determine absence of side effects and adverse reactions to therapy.

HERBAL ALERT 43-1

Diuretics

- Aloe can decrease the serum potassium level, thereby causing hypokalemia, when taken with a potassium-wasting diuretic such as a thiazide.
- Gingko may increase blood pressure when taken with thiazide diuretics.
- Licorice can increase potassium loss, leading to hypokalemia.
- Hawthorne may potentiate hypotension.

Loop diuretics can increase renal blood flow up to 40%. Furosemide is a frequently prescribed diuretic for patients whose creatinine clearance is less than 30/min and for those with end-stage renal disease. This group of diuretics causes excretion of calcium, unlike thiazides, which inhibit calcium loss.

The first loop diuretic marketed was ethacrynic acid (Edecrin), followed by furosemide (Lasix) and then bumetanide (Bumex), which is more potent than furosemide on a milligram-for-milligram basis. Furosemide and bumetanide are derivatives of sulfonamides. Ethacrynic acid, a phenoxyacetic acid derivative, is a seldom-chosen loop diuretic. It is usually reserved for patients who are allergic to sulfa drugs. Prototype Drug Chart 43-2 lists the drug data for the loop diuretic furosemide.

Pharmacokinetics Loop diuretics are rapidly absorbed by the GI tract. These drugs are highly protein bound with half-lives that vary from 30 minutes to 1.5 hours. Loop diuretics compete for protein-binding sites with other highly protein-bound drugs.

Pharmacodynamics Loop diuretics have a great **saluretic** (sodium-chloride–losing) or **natriuretic** (sodium-losing) effect and can cause rapid diuresis, decreasing vascular fluid volume and causing a decrease in cardiac output and blood pressure. Because furosemide is a more potent diuretic than thiazide diuretics, it causes a vasodilatory effect; thus renal blood flow increases before diuresis. Furosemide is used when other conservative measures, such as sodium restriction and use of less potent diuretics, fail. The oral dose of furosemide is usually twice that of an intravenous (IV) dose.

The onset of action of loop diuretics occurs within 30 to 60 minutes. The onset of action for IV furosemide is 5 minutes. Duration of action is shorter than that of the thiazides.

Side Effects and Adverse Reactions. The most common side effects of loop diuretics are fluid and electrolyte imbalances such as hypokalemia, hyponatremia, hypocalcemia, hypomagnesemia, and hypochloremia. Hypochloremic metabolic alkalosis may result, which can worsen hypokalemia. Orthostatic hypotension can occur. Thrombocytopenia, skin disturbances, and transient deafness are rarely seen. Table 43-3 lists the physiologic and laboratory changes associated with loop diuretics.

Drug Interactions. The major drug interaction is with digitalis preparations. If the patient takes digoxin with a loop diuretic, digitalis toxicity can result. Hypokalemia enhances the action of digoxin and increases the risk for digitalis toxicity. The patient needs potassium replacement with food or supplements. Serum potassium levels should be closely monitored, especially when the patient is taking high dosages of

PROTOTYPE DRUG CHART 43-2

Furosemide

Drug Class

Loop diuretic
Trade Names: Lasix
Pregnancy Category: C

Dosage

A: PO: 20-80 mg single dose/d; may increase in 6-8 h, 20-40 mg; maint: 40-120 mg/d; *max:* 600 mg/d
A: IM/IV: 20-40 mg over 1-2 min IV; repeat 20 mg in 2 h; *max:* 4 mg/min inf
C: PO: 1-2 mg/kg single dose; repeat in 6-8 h *max:* 6 mg/kg/d
C: IM/IV: 1-2 mg/kg single dose; repeat 1 mg/kg in 6-12 h; *max:* 6 mg/kg/d

Contraindications

Presence of severe electrolyte imbalances, hypovolemia, anuria, hepatic coma, hypersensitivity to sulfonamides
Caution: Heart failure, diabetes mellitus, hypotension, systemic lupus erythematosus, gout, patients with hearing impairment

Drug-Lab-Food Interactions

Drug: Increase orthostatic hypotension with alcohol; increase ototoxicity with aminoglycosides; increase bleeding with anticoagulants; increase potassium loss with steroids, Amphotericin B, amiodarone; increase digitalis toxicity and cardiac dysrhythmias with digoxin and hypokalemia; increase lithium toxicity; increase amphotericin B ototoxicity and nephrotoxicity
Food: licorice may increase potassium loss
Lab: Increase BUN, blood/urine glucose, serum uric acid, ammonia; decrease potassium, sodium, calcium, magnesium, chloride serum levels
Herbs: Hawthorn may potentiate hypotension, Ginseng may decrease action of loop diuretics

Pharmacokinetics

Absorption: PO: Readily absorbed from GI tract
Distribution: PB: 95%
Metabolism: t½: 30-60 min
Excretion: In urine, some in feces; crosses placenta

Pharmacodynamics

PO: Onset: less than 60 min
Peak: 1-4 h
Duration: UK
IV: Onset: 5 min
Peak: 20-30 min
Duration: 2 h

Therapeutic Effects/Uses

To treat fluid retention/fluid overload caused by HF, renal dysfunction, cirrhosis; hypertension; acute pulmonary edema
Mode of Action: Inhibition of sodium and water reabsorption from loop of Henle and distal renal tubules; potassium, magnesium, and calcium also may be excreted

Side Effects

Nausea, diarrhea, electrolyte imbalances, vertigo, abdominal cramping, constipation, rash, headache, weakness, ECG changes, blurred vision, photosensitivity, muscle cramping

Adverse Reactions

Severe dehydration; marked hypotension, hyperglycemia, gout, hearing loss
Life-threatening: Renal failure, thrombocytopenia, agranulocytosis

A, Adult; *BUN,* blood urea nitrogen; *C,* child; *d,* day; *ECG,* electrocardiogram; *GI,* gastrointestinal; *h,* hour; *HF,* heart failure; *IM,* intramuscular; *inf,* infusion; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *t ½,* half-life.

loop diuretics. Table 43-4 lists the data for the four loop diuretics.

OSMOTIC DIURETICS

Osmotic diuretics increase the **osmolality** (concentration) and sodium reabsorption in the proximal tubule and loop of Henle. Sodium, chloride, potassium (to a lesser degree), and water are excreted. This group of drugs is used to prevent kidney failure, to decrease intracranial pressure (ICP) (e.g., in cerebral edema), and to decrease intraocular pressure (IOP) (e.g., in glaucoma). Mannitol is a potent osmotic potassium-wasting diuretic frequently used in emergency situations such as ICP and IOP. In addition, mannitol can be used with cisplatin and carboplatin in cancer chemotherapy to induce a frank diuresis and decreased side effects of treatment.

Mannitol is the most frequently prescribed osmotic diuretic, followed by urea. Diuresis occurs within 1 to 3 hours after IV administration. Table 43-4 describes Mannitol.

Side Effects and Adverse Reactions. The side effects and adverse reactions of mannitol include fluid and electrolyte imbalance, pulmonary edema from rapid shift of fluids, nausea, vomiting, tachycardia from rapid fluid loss, and acidosis. Crystallization of mannitol in the vial may occur when the drug is exposed to a low temperature. The vial should be warmed to dissolve the crystals. The mannitol solution should not be used for IV infusion if crystals are present and have not been dissolved.

TABLE 43-3 PHYSIOLOGIC AND LABORATORY CHANGES ASSOCIATED WITH LOOP DIURETICS

PHYSIOLOGIC/LABORATORY CHANGES	POSSIBLE EFFECTS OF LOOP (HIGH-CEILING) DIURETICS
Physiologic Changes	
Hypotension	Postural (orthostatic) hypotension can result because of ECFV deficit.
Ototoxicity	Hearing impairment, although rare, may occur. It is more common with use of ethacrynic acid. Diuretics in other categories are not considered ototoxic. Caution: Avoid taking a loop diuretic with a drug that can be ototoxic, such as an aminoglycoside.
Skin disturbances	Pruritus, urticaria, exfoliative dermatitis, and purpura may occur in some persons allergic to the drug or when taking the loop diuretic in high doses over a long period.
Photosensitivity	When exposed to sun or sunlamp for a prolonged time, severe sunburn could result. Patient should use sunblock and avoid long sun exposure.
Hypovolemia	Excess extracellular fluid is lost through increased urine excretion.
Laboratory Changes	
Hypokalemia, hypomagnesemia, hyponatremia, hypocalcemia, hypochloremia	Potassium, magnesium, sodium, calcium, and chloride are lost from the body from increased urine excretion. Chloride, an anion, is attached to the cations potassium and sodium; thus, chloride is lost along with potassium and sodium.
Hyperglycemia	Increased glycogenolysis may contribute to elevated blood sugar level. Patients with diabetes should closely monitor blood glucose levels when taking a loop diuretic.
Hyperuricemia	Elevated uric acid levels are common in patients susceptible to gout.
Elevated BUN and creatinine	These elevations may result from ECFV loss. Hemoconcentration can cause elevated BUN and creatinine levels, which are reversible when fluid volume returns to normal levels.
Thrombocytopenia, leukopenia	Decreases in platelet and white blood cell counts are rare, but they should be closely monitored.
Elevated lipids	Loop diuretics can decrease high-density lipoproteins (HDL) and increase low-density lipoproteins (LDL). Patients with elevated cholesterol levels should have their HDL and LDL levels checked. Regardless of the lipid effects, loop diuretics are useful for patients with serious fluid retention caused by a cardiac condition such as HF.

BUN, Blood urea nitrogen; *ECFV,* extracellular fluid volume; *HF,* heart failure.

Contraindications. Mannitol must be given with extreme caution to patients who have heart disease and HF. It should be immediately discontinued if the patient develops HF or renal failure.

Nursing Process

Patient-Centered Collaborative Care

Diuretics: Loop

Assessment

- Obtain a history of drugs that are taken daily. Note if patient is taking a drug that may interact with loop diuretic (e.g., alcohol, aminoglycosides, anticoagulants, corticosteroids, lithium, amphotericin B, digitalis). Recognize that furosemide is highly protein-bound and can displace other protein-bound drugs such as warfarin (Coumadin).
- Assess vital signs, serum electrolytes, weight, and urine output for baseline levels.
- Compare patient's drug dose with recommended dose, and report discrepancy.
- Note whether patient is hypersensitive to sulfonamides.

Nursing Diagnoses

- Risk for deficient fluid volume related to fluid loss with excessive use of loop diuretics
- Risk for electrolyte imbalance (potassium deficit related to excessive use of loop diuretics)

Planning

- Patient's edema and/or hypertension will be decreased.
- Patient's serum chemistry levels will remain within normal ranges.

Nursing Interventions

- Monitor urinary output to determine body fluid gain or loss. Urinary output should be at least 30 mL/h or 600 mL/24 h.
- Notify health care provider if urine output does not increase. Severe renal disorder may be present.
- Weigh patient to determine fluid loss or gain. A loss of 2.2 lb is equivalent to a fluid loss of 1 L.
- Monitor vital signs. Be alert for marked decrease in blood pressure.

TABLE 43-4 DIURETICS: LOOP, OSMOTICS, AND CARBONIC ANHYDRASE INHIBITORS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Loop		
bumetanide	A: PO: 0.5-2.0 mg/d; *max:* 10 mg/d IV: 0.5-1 mg/dose slowly over 1 min; repeat in 2-4 h	Treatment of renal disease and hypertension and edema associated with HF. Similar effects as furosemide. Pregnancy category: C; PB: 96%; t½: 1-1.5 h
ethacrynic acid (Edecrin)	A: PO: 50-100 mg/d or b.i.d.; *max:* 400 mg/d C: PO: 1 mg/kg/d; *max:* 3 mg/kg/d A: IV: 0.5-1 mg/kg/dose or 50-100 mg/d C: IV: 1 mg/kg once daily	For severe edema (pulmonary and peripheral). Potent diuretic with rapid action. Also used for hypercalcemia. Moderate to high doses may cause ototoxicity. Pregnancy category: B; PB: 95%; t½: 1-1.5 h
furosemide (Lasix)	See Prototype Drug Chart 43-2.	
torsemide (Demadex)	Hypertension: A: PO: Initially: 5 mg/d; maint: PO: 5-10 mg/d; HF: A: PO/IV: 10-20 mg/d; *max:* 200 mg/d	Similar to furosemide. Pregnancy category: B; PB: 97%-99%; t½: 2-4 h
Osmotics		
mannitol	ICP/IOP: A: IV: Initially 1-2 g/kg followed by 0.25-1 g/kg; 15%-25% sol infused over 30-90 min Edema, ascites, or oliguria: A: IV: 50-100 g; 10%-20% sol infused over 90 min–6 h	For oliguria and decreasing ICP. To prevent acute renal failure. Used in narrow-angle glaucoma for reducing IOP. Patient should have effective renal function. Potent diuretic. Pregnancy category: C; PB: UK; t½: 15 min–1.5 h
Carbonic Anhydrase Inhibitors		
acetazolamide (Diamox)	Glaucoma: A: PO/IV: 250 mg once daily/q.i.d.; *max:* 1 g/d A: IV: 500 mg, may repeat in 2-4 h; *max:* 1 g/d A: SR: 500 mg q12h; *max:* 1000 mg/d Edema: A: PO: IV: 250-375 mg in morning	For edema, treating absence (petit mal) seizures, and open-angle glaucoma. May cause hyperglycemia, hyperuricemia, and hypercalcemia. Metabolic acidosis can result. Pregnancy category: C; PB: 90%; t½: 10-15 h
methazolamide (Neptazane)	A: PO: 50-100 mg b.i.d./t.i.d.; *max:* 300 mg/d	Similar to dichlorphenamide. Pregnancy category: C; PB: 50%-60%; t½: 14 h

A, Adult; *b.i.d.,* twice a day; *C,* child; *d,* day; *h,* hour; *HF,* heart failure; *ICP,* intracranial pressure; *inf,* infusion; *IOP,* intraocular pressure; *IV,* intravenous; *maint,* maintenance dose; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *sol,* solution; *SR,* sustained-release; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *y,* year; *>,* greater than.

- Administer IV furosemide slowly; hearing loss may occur if rapidly injected.
- Observe for signs and symptoms of hypokalemia (less than 3.5 mEq/L), such as muscle weakness, abdominal distention, leg cramps, and/or cardiac dysrhythmias.
- Monitor serum potassium levels, especially when patient is taking digoxin. Hypokalemia enhances action of digitalis, causing digitalis toxicity.

Patient Teaching

General

- Advise patient to take furosemide in morning and *not* in evening to prevent sleep disturbance and nocturia.

Side Effects

- Teach patient to rise slowly from lying or sitting to standing to prevent dizziness resulting from fluid loss.

Diet

- Suggest taking furosemide with food to avoid nausea.

Cultural Considerations

- Respect cultural practices and values. If patient from a different background tells health care provider that she or he does not eat fruits and vegetables, the nurse may have two options: to encourage patient to eat fruits and vegetables or to contact health care provider so that an adequate potassium supplement can be prescribed to overcome potassium loss. An interpreter may be necessary.
- Emphasize the importance of patient taking potassium supplement with potassium-wasting diuretic. In addition, advise patient of consequences and dangers of not taking potassium supplements or lacking appropriate nutrition while taking potassium-wasting diuretics.

Evaluation

- Evaluate effectiveness of drug action, such as decreased fluid retention or fluid overload, decreased respiratory distress, and increased cardiac output.
- Check for side effects and increased urine output.

CARBONIC ANHYDRASE INHIBITORS

The carbonic anhydrase inhibitors acetazolamide, dichlorphenamide, ethoxzolamide, and methazolamide block the action of the enzyme *carbonic anhydrase,* which is needed to maintain the body's acid-base balance (hydrogen and bicarbonate ion balance). Inhibition of this enzyme causes increased sodium, potassium, and bicarbonate excretion. With prolonged use, metabolic acidosis can occur.

This group of drugs is used primarily to decrease IOP in patients with open-angle (chronic) glaucoma. These drugs are not used in narrow-angle or acute glaucoma. Other uses include diuresis, management of epilepsy, and treatment of high-altitude or acute mountain sickness. Table 43-4 presents the drug data for carbonic anhydrase inhibitor diuretics. The drug may also be used for a patient in metabolic alkalosis who needs a diuretic. Carbonic anhydrase inhibitors may be alternated with a loop diuretic.

Side Effects and Adverse Reactions. Acetazolamide can cause fluid and electrolyte imbalance, metabolic acidosis, nausea, vomiting, anorexia, confusion, orthostatic hypotension, and crystalluria. Hemolytic anemia and renal calculi can also occur. These drugs are contraindicated during the first trimester of pregnancy.

POTASSIUM-SPARING DIURETICS

Potassium-sparing diuretics, which are weaker than thiazides and loop diuretics, are used as mild diuretics or in combination with another diuretic (e.g., hydrochlorothiazide, antihypertensive drugs). Continuous use of potassium-wasting diuretics requires a daily oral potassium supplement, because the kidneys excrete potassium, sodium, and body water. However, potassium supplements are *not* used when the patient takes a potassium-sparing diuretic; in fact, serum potassium excess, called **hyperkalemia,** results when a potassium supplement is taken with a potassium-sparing diuretic. The serum potassium should be periodically monitored when the patient continuously takes a potassium-sparing diuretic. If the serum potassium level is greater than 5.3 mEq/L, the patient should discontinue the potassium-sparing diuretic and restrict foods high in potassium.

Potassium-sparing diuretics act primarily in the collecting duct renal tubules and late distal tubule to promote sodium and water excretion and potassium retention. The drugs interfere with the sodium-potassium pump controlled by the mineralocorticoid hormone aldosterone (sodium retained and potassium excreted).

Spironolactone (Aldactone), an aldosterone antagonist discovered in 1958, was the first potassium-sparing diuretic. Aldosterone is a mineralocorticoid hormone that promotes sodium retention and potassium excretion. Spironolactone blocks the action of aldosterone and inhibits the sodium-potassium pump (i.e., potassium is retained and sodium is excreted). Spironolactone (Aldactone) has been prescribed by cardiologists for patients with cardiac disorders because of its potassium-retaining effect. As a result of the action of spironolactone, the heart rate is more regular, and the possibility of myocardial fibrosis is decreased. The effects of spironolactone may take 48 hours.

Amiloride (Midamor), triamterene (Dyrenium), and eplerenone (Inspra) are additional commonly prescribed potassium-sparing diuretics. Amiloride and eplerenone are effective as antihypertensive agents. Triamterene is useful in the treatment of edema caused by HF or cirrhosis of the liver. Low doses of spironolactone (Aldactone) and eplerenone are effective for chronic HF. Spironolactone, amiloride, triamterene, and eplerenone should not be taken with ACE inhibitors and angiotensin II receptor blockers (ARBs) because they can also increase serum potassium levels. Prototype Drug Chart 43-3 provides the pharmacologic data for spironolactone.

When potassium-sparing diuretics are used alone, they are less effective than when used in combination to reduce body fluid and sodium. These drugs are usually combined with a potassium-wasting diuretic, primarily hydrochlorothiazide or a loop diuretic. The combination of potassium-sparing and potassium-wasting diuretics intensifies the diuretic effect and prevents potassium loss. The common combination diuretics contain spironolactone and hydrochlorothiazide (Aldactazide), amiloride and hydrochlorothiazide (HCTZ), and triamterene and hydrochlorothiazide (Dyazide, Maxzide). Table 43-5 lists the potassium-sparing diuretics and the combination potassium-wasting and potassium-sparing diuretics.

Side Effects and Adverse Reactions. The main side effect of these drugs is hyperkalemia. Caution must be used when giving potassium-sparing diuretics to a patient with poor renal function, because the kidneys excrete 80% to 90% of potassium. Urine output should be at least 600 mL/day. Patients should *not* use potassium supplements while taking potassium-sparing diuretics, unless the serum potassium level is low. If a potassium-sparing diuretic is given with antihypertensive ACE inhibitors, hyperkalemia could become severe or life threatening, because both drugs retain potassium. Monitoring serum potassium levels is essential to safe drug therapy. GI disturbances (anorexia, nausea, vomiting, diarrhea, and numbness and tingling of the hands and feet) can occur.

Nursing Process

Patient-Centered Collaborative Care

Diuretics: Potassium-Sparing

Assessment

- Obtain a history of drugs taken daily. Note whether patient is taking a potassium supplement or using a salt substitute.
- Assess vital signs, serum electrolytes, weight, and urinary output for baseline levels.

PROTOTYPE DRUG CHART 43-3

Spironolactone

Drug Class

Potassium-sparing diuretic
Trade Name: Aldactone
Pregnancy Category: C

Dosage

Edema:
A: PO: 25-200 mg/d in divided doses; *max:* 400 mg/d
C: PO: 1.5-3.3 mg/kg/d in divided doses; *max:* 3.3 mg/kg/d
Hypertension:
A: PO: 50-100 mg/d; *max:* 400 mg/d

Contraindications

Severe kidney or hepatic disease, anuria, severe hyperkalemia
Caution: Renal or hepatic dysfunction, diabetes mellitus

Drug-Lab-Food Interactions

Drug: Increase serum potassium level with potassium supplements; increase effects of antihypertensives and lithium; life threatening: hyperkalemia if given with ACE inhibitor
Lab: Increase serum potassium level; may increase BUN, AST, alkaline phosphatase levels; decrease serum sodium, chloride

Pharmacokinetics

Absorption: PO: Rapidly absorbed from GI tract
Distribution: PB: 90%
Metabolism: $t_{1/2}$: 1.5-2 h
Excretion: In urine, mostly as metabolites and bile

Pharmacodynamics

PO: Onset: UK
Peak: 2-3 d
Duration: 2-3 days or longer

Therapeutic Effects/Uses

To increase urine output; to treat fluid retention/overload associated with HF, hepatic cirrhosis, or nephrotic syndrome
Mode of Action: Acts on distal renal tubules to promote sodium and water excretion and potassium retention

Side Effects

Nausea, vomiting, diarrhea, rash, dizziness, headache, weakness, dry mouth, photosensitivity

Adverse Reactions

Life-threatening: Severe hyperkalemia, thrombocytopenia, megaloblastic anemia

A, Adult; *ACE,* angiotensin-converting enzyme; *AST,* aspartate aminotransferase; *BUN,* blood urea nitrogen; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *HF,* heart failure; *PB,* protein-binding; *p.c.,* after meals; *PO,* by mouth; $t_{1/2}$, half-life.

TABLE 43-5 DIURETICS: POTASSIUM-SPARING

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Single Agents		
amiloride HCl (Midamor)	A: PO: 5-10 mg/d; *max:* 20 mg/d	For diuretic-induced hypokalemia; used for hypertension, HF, and cirrhosis of the liver. Monitor serum potassium level to detect hyperkalemia. Pregnancy category: B; PB: 40%; $t_{1/2}$: 6-9 h
eplerenone (Inspra)	A: PO: 25-50 mg/d; *max:* 100 mg/d for hypertension; 50 mg/d for HF	For hypertension or chronic HF post MI. Approved in 2002. Also classified as a selective aldosterone receptor blocker. Serum potassium should be monitored to detect hyperkalemia. Pregnancy category: B ; PB: 50%; $t_{1/2}$: 4-6 h
spironolactone (Aldactone)	See Prototype Drug Chart 43-3.	
triamterene (Dyrenium)	A: PO: Initially 50-100 mg b.i.d.; *max:* 300 mg/d	For edema and hypokalemia. May increase excretion of magnesium. May cause severe hyperkalemia with resultant life-threatening cardiac dysrhythmias. Pregnancy category: C; PB: 67%; $t_{1/2}$: 1-2 h
Combinations		
amiloride HCl and hydrochlorothiazide (Moduretic)	A: PO: 1-2 tab (amiloride 5 mg/hydrochlorothiazide 50 mg)	Combinations contain potassium-wasting and potassium-sparing diuretics. Drugs are to control hypertension and edema. They are used to prevent the occurrence of hypokalemia.
spironolactone and hydrochlorothiazide (Aldactazide)	A: PO: 1 tab (25 mg spironolactone/25 mg HCTZ); *max:* 200 mg/d of each	Same as Moduretic
triamterene and hydrochlorothiazide (Dyazide, Maxzide)	A: PO: 1-2 cap p.c. (triamterene 37.5 mg/hydrochlorothiazide 25 mg)	Same as Moduretic

A, Adult; *b.i.d.,* twice a day; *C,* child; *cap,* capsule; *d,* day; *h,* hour; *HF,* heart failure; *MI,* myocardial infarction; *PB,* protein-binding; *p.c.,* after meals; *PO,* by mouth; $t_{1/2}$, half-life; *tab,* tablet; *UK,* unknown.

- Compare patient's drug dose with recommended dose, and report any discrepancy.

Nursing Diagnoses

- Risk for deficient fluid volume related to fluid loss with excessive use of potassium-sparing diuretic
- Risk for electrolyte imbalance (potassium excess related to excessive use of potassium-sparing diuretic)

Planning

- Patient's fluid retention and blood pressure will be decreased.
- Patient's serum electrolytes will remain within normal ranges.

Nursing Interventions

- Note the half-life of spironolactone. With a long half-life, drug dose is usually administered once a day, sometimes twice a day.
- Monitor urinary output. Urine output should increase. Report if urine output is <30 mL/h or <600 mL/day.
- Record vital signs. Report abnormal changes.
- Observe for signs and symptoms of hyperkalemia (serum potassium >5.3 mEq/L). Nausea, diarrhea, abdominal cramps, numbness and tingling of the hands and feet, leg cramps, tachycardia and later bradycardia, peaked narrow T wave on electrocardiogram, or oliguria may signal hyperkalemia.
- Administer spironolactone in the morning and not in the evening to avoid nocturia.

Patient Teaching

General

- Teach patient to take spironolactone with or after meals to avoid nausea.
- Encourage patient not to discontinue drug without consulting health care provider.

Side Effects

- Caution patient to avoid exposure to direct sunlight, because drug can cause photosensitivity.
- Advise patient to report possible side effects of drug (e.g., rash, dizziness, weakness, GI upset).

Diet

- Advise patients with high serum potassium levels to avoid foods rich in potassium when taking potassium-sparing diuretics.

Evaluation

- Evaluate effectiveness of potassium-sparing diuretic (e.g., triamterene). Fluid retention (edema) should be decreased or absent.
- Determine whether urine output has increased and serum potassium level is within normal range.

CRITICAL THINKING CASE STUDY

JQ, a 58-year-old patient, has been recently diagnosed with hypertension. His resting blood pressure is 158/92. He is prescribed hydrochlorothiazide 50 mg/day and told to eat foods rich in potassium.

1. How does hydrochlorothiazide differ from furosemide (Lasix)? What are their similarities and differences?
2. Why is it necessary for JQ to eat foods rich in potassium when taking hydrochlorothiazide? Explain your answer.
3. What are the nursing interventions that should be considered while JQ takes hydrochlorothiazide?

   After 1 month on hydrochlorothiazide therapy, JQ becomes weak and complains of nausea and vomiting. His muscles are "soft." His serum potassium level is 3.3 mEq/L. JQ's diuretic is changed to triamterene/hydrochlorothiazide (Dyazide). Again, he is advised to eat foods rich in potassium.
4. Explain the rationale for changing JQ's diuretic.
5. Should JQ receive a potassium supplement? Explain your answer.
6. What nursing interventions should the nurse follow for JQ?
7. What care plan should the nurse develop for JQ in relation to patient teaching?
8. What medical follow-up care is needed for JQ?

NCLEX STUDY QUESTIONS

1. A patient is taking hydrochlorothiazide (HCTZ) 50 mg/day and digoxin (Lanoxin) 0.25 mg/day. The nurse plans to monitor the patient for which potential electrolyte imbalance?
   - a. Hypocalcemia
   - b. Hypokalemia
   - c. Hyperkalemia
   - d. Hypermagnesemia
2. The nurse knows that which statement is correct regarding nursing care of a patient receiving hydrochlorothiazide (HCTZ)? (Select all that apply.)
   - a. Monitor patient for signs of hypoglycemia.
   - b. Administer ordered potassium supplements.
   - c. Monitor serum potassium and uric acid levels.
   - d. Assess blood pressure before administration.
   - e. Notify health care provider if patient has had oliguria for 24 hours.
   - f. Assess for decreased cholesterol and triglyceride levels.
3. A patient has heart failure, and a high dose of furosemide (Lasix) is ordered. What suggests a favorable response to Lasix?
   - a. Decrease in level of consciousness and sleeping more
   - b. Respiratory rate decreases from 28/min to 20/min and the depth increases.
   - c. Increased congestion heard in breath sounds and complains of shortness of breath
   - d. Urine output of 50 mL/4 h and intake of 200 mL
4. What does the nurse know to be correct concerning the use of mannitol (Osmitrol) in patients?
   - a. Decreases intracranial pressure
   - b. Increases intraocular pressure
   - c. Causes sodium and potassium retention
   - d. Causes diuresis in several days
5. What should the nurse do when a patient is taking furosemide (Lasix)?
   - a. Instruct patient to change positions quickly when getting out of bed.
   - b. Assess blood pressure before administration.
   - c. Administer at bedtime for maximum effectiveness
   - d. Teach to avoid fruits to prevent hyperkalemia.
6. For the patient taking a diuretic, a combination such as triamterene and hydrochlorothiazide may be prescribed. The nurse realizes that this combination is ordered for which purpose?
   - a. To decrease serum potassium level
   - b. To increase serum potassium level
   - c. To decrease glucose level
   - d. To increase glucose level
7. The patient has been receiving spironolactone (Aldactone) 50 mg/day for heart failure. The nurse should closely monitor the patient for which condition?
   - a. Hypokalemia
   - b. Hyperkalemia
   - c. Hypoglycemia
   - d. Hypermagnesemia

Answers: 1, b; 2, b, c, d, e; 3, b; 4, a; 5, b; 6, b; 7, b.

HYPERTENSION

Hypertension is an increase in blood pressure such that the systolic pressure is greater than 140 mm Hg and the diastolic pressure is greater than 90 mm Hg. **Essential hypertension** is the most common type, affecting 90% of persons with high blood pressure. The exact origin of essential hypertension is unknown; however, contributing factors may include family history of hypertension, hyperlipidemia, African-American background, diabetes, aging, stress, excessive alcohol ingestion, smoking, and obesity. Ten percent of hypertension cases are related to renal and endocrine disorders and are classified as **secondary hypertension**.

Selected Regulators of Blood Pressure

The kidneys and blood vessels strive to regulate and maintain a "normal" blood pressure. The kidneys regulate blood pressure by control of fluid volume and the renin-angiotensin-aldosterone system. Kidneys control sodium and water elimination/retention, which affects cardiac output and systemic arterial blood pressure. Figure 44-1 illustrates the renin-angiotensin-aldosterone system (RAAS). Renin (from the renal cells) stimulates production of angiotensin II (a potent vasoconstrictor), which causes the release of aldosterone (adrenal hormone that promotes sodium retention and thereby water retention). Retention of sodium and water causes fluid volume to increase, elevating blood pressure.

The baroreceptors in the aorta and carotid sinus and the vasomotor center in the medulla also assist in the regulation of blood pressure. Catecholamines such as norepinephrine, released from the sympathetic nerve terminals, and epinephrine, released from the adrenal medulla, increase blood pressure through vasoconstriction activity.

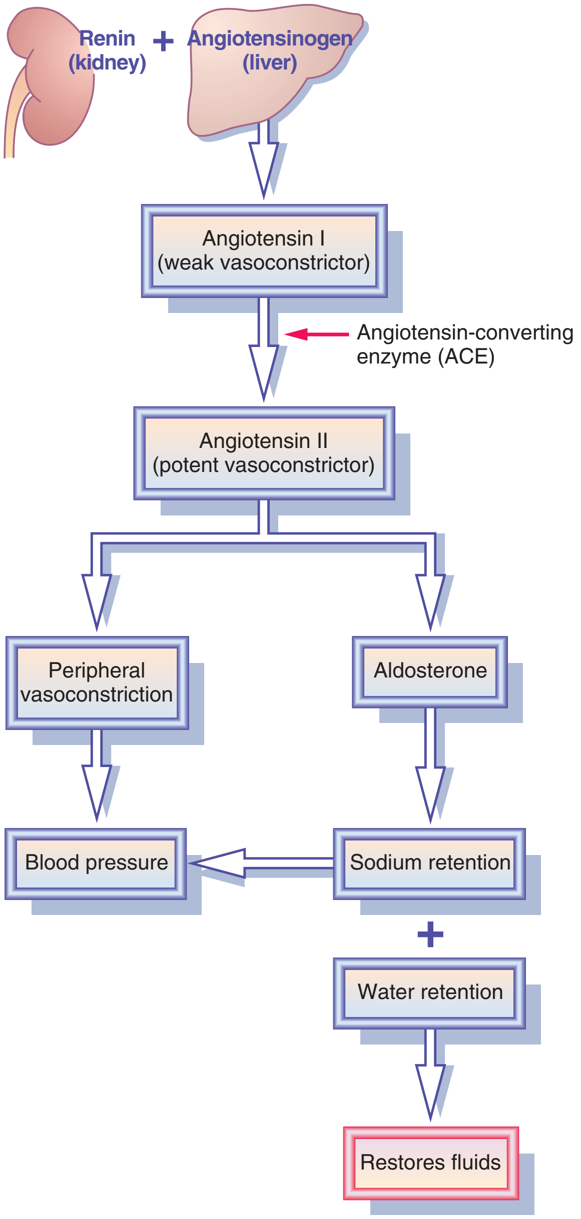

FIGURE 44–1 The renin-angiotensin-aldosterone system (RAAS). Renin, an enzyme located in the juxtaglomerular cells of the kidney, is released when blood pressure decreases. This diagram shows how the RAAS restores fluid balance and stabilizes blood pressure.

Other hormones that contribute to blood pressure regulation are antidiuretic hormone (ADH), atrial natriuretic peptide (ANP) hormone, and brain natriuretic peptide (BNP) hormone. ADH is produced by the hypothalamus and is stored and released by the posterior pituitary gland (neurohypophysis). This hormone stimulates the kidneys to conserve and retain water when there is a fluid volume deficit. When there is fluid overload, ADH secretion is inhibited, and the kidneys then excrete more water.

Physiologic Risk Factors

Certain physiologic risk factors contribute to hypertension. A diet high in saturated fat and simple carbohydrates can increase blood pressure. Carbohydrate intake can affect sympathetic nervous activity. Alcohol increases renin secretions, causing the production of angiotensin II. Obesity affects the sympathetic and cardiovascular systems by increasing cardiac output, stroke volume, and left ventricular filling. Two-thirds of hypertensive persons are obese. Normally weight loss can decrease hypertension, as can mild to moderate sodium restriction.

Cultural Responses to Antihypertensive Agents

African Americans are more likely to develop hypertension at an earlier age than white Americans. They also have a higher mortality rate from hypertension than the white population. The use of beta-adrenergic blockers (beta blockers) and angiotensin-converting enzyme (ACE) inhibitors is less effective for the control of hypertension in African Americans unless the drug is combined or given with a diuretic. This group is susceptible to low-renin hypertension; therefore, they do not respond well to beta blockers and ACE inhibitors. The antihypertensive drugs that are effective for African Americans are alpha$_1$ blockers and calcium channel blockers (calcium blockers). African-American patients do respond to diuretics as the initial monotherapy for controlling hypertension. White patients usually have high-renin hypertension and respond well to all antihypertensive agents.

Asian Americans are twice as sensitive as whites to beta blockers and other antihypertensives. A reduction in antihypertensive dosing is frequently needed. Native Americans have a reduced or lower response to beta blockers compared with whites. Monitoring blood pressure and drug dosing should be an ongoing assessment for patients in these cultural groups.

Hypertension in Older Adults

By 65 years of age, 26% of men and 30% of women are hypertensive. Between 65 and 75 years of age, 30% of men and 45% of women are hypertensive. Both systolic and diastolic hypertension are associated with increased cardiovascular morbidity and mortality. With antihypertensive therapy, the greatest decrease in cardiovascular disorders is 34% for stroke and 19% for coronary heart disease.

One of the troublesome side effects of the use of antihypertensive agents in older adults, especially frail or institutionalized persons, is orthostatic (postural) hypotension.

This episode of sudden low blood pressure presents dizziness due to blood pooling in lower extremities when an individual changes to an upright position. In older adults, the sympathetic nervous system does not respond as quickly to correct the situation, especially when potentiated by antihypertensive drug administration. If orthostatic hypotension occurs, the antihypertensive drug dose may need to be decreased or another antihypertensive drug used. Older adults with hypertension should be instructed to modify their lifestyle activities. This includes restricting dietary sodium to 2400 mg daily, avoiding tobacco, modifying diet, exercising, and decreasing stress.

NONPHARMACOLOGIC CONTROL OF HYPERTENSION

A sufficient decrease in blood pressure can be accomplished by nonpharmacologic methods. There are many nonpharmacologic ways to decrease blood pressure, but if the systolic pressure is greater than 140 mm Hg, **antihypertensive** drugs are generally ordered. Nondrug methods to decrease blood pressure include stress-reduction techniques, exercise, salt restriction, decreased alcohol ingestion, and smoking cessation.

When hypertension cannot be controlled by nonpharmacologic means, antihypertensive drugs are prescribed. However, nonpharmacologic methods should be combined with antihypertensive drugs to control hypertension.

GUIDELINES FOR HYPERTENSION

Blood pressure guidelines for determining hypertension have been revised and are contained in the Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure, or JNC 7. The purpose of these guidelines is to decrease the risk of cardiovascular disease (CVD) in the American population. The guideline for normal blood pressure is less than 120/80 mm Hg. *Prehypertension* is defined as systolic blood pressure (SBP) of 120 to 139 and diastolic blood pressure (DBP) of 80 to 89. Stage 1 hypertension falls between 140/90 and 159/99, and stage 2 hypertension is 160/100 or greater.

Two out of three patients with hypertension have uncontrolled blood pressure or are not optimally treated. SBP is more important than DBP as a CVD risk for patients 50 years of age or older. According to the JNC 7, if the blood pressure is greater than 20/10 mm Hg above goal, a drug regimen should be started. CVD risk doubles with each increase of 20/10 mm Hg, starting at 115/75 mm Hg.

PHARMACOLOGIC CONTROL OF HYPERTENSION

An individualized approach to the treatment of hypertension is used by many health care providers. All drugs are considered *initial agents* when first prescribed for hypertension. Reduction of other cardiovascular risk factors and the use of fewer drugs (i.e., substituting instead of adding drugs) at the lowest effective doses are emphasized. Often more than one antihypertensive is used to control blood pressure, which also may lead to less adverse effects.

Antihypertensive drugs, used either singly or in combination with other drugs, are classified into six categories: (1) diuretics, (2) sympatholytics (sympathetic depressants), (3) direct-acting arteriolar vasodilators, (4) ACE inhibitors, (5) angiotensin II receptor blockers (ARBs), and (6) calcium channel blockers.

Diuretics

Diuretics promote sodium depletion, which decreases extracellular fluid volume (ECFV). Diuretics are effective as first-line drugs for treating mild hypertension. Hydrochlorothiazide (HCTZ) is the most frequently prescribed diuretic for controlling mild hypertension by decreasing excess fluid volume. It can be used alone for recently diagnosed or mild hypertension or with other antihypertensive drugs. Many antihypertensive drugs can cause fluid retention; therefore diuretics are often administered together with antihypertensive agents. The various types of diuretics are discussed in Chapter 43.

Thiazide diuretics are not recommended for patients with renal insufficiency (creatinine clearance <30 mL/min). The loop (high-ceiling) diuretics such as furosemide (Lasix) are usually recommended, because they do not depress renal blood flow. Loop diuretics are not used if hypertension is the result of renin-angiotensin-aldosterone system involvement because they tend to elevate serum renin level immediately. Instead of a single thiazide drug, a combination of potassium-wasting and potassium-sparing diuretics may be useful; less potassium excretion would occur. In addition, thiazides can be combined with other antihypertensive drugs to increase their effectiveness. Box 44-1 lists the combinations of thiazides with other drugs. Many drug products on the market include combinations of thiazide diuretics and potassium-sparing diuretics, beta blockers, ACE inhibitors, or angiotensin II receptor blockers. ACE inhibitors tend to increase serum potassium (K) levels, so when they are combined with a thiazide diuretic, serum potassium loss is minimized.

Sympatholytics (Sympathetic Depressants)

The **sympatholytics** comprise five groups of drugs: (1) beta-adrenergic blockers, (2) centrally acting alpha$_2$ agonists, (3) alpha-adrenergic blockers, (4) adrenergic neuron blockers (peripherally acting sympatholytics), and (5) alpha$_1$- and beta$_1$-adrenergic blockers. Beta-adrenergic blockers block the beta receptors, and alpha-adrenergic blockers block the alpha receptors.

Beta-Adrenergic Blockers

Beta-adrenergic blockers, frequently called *beta blockers*, are used as antihypertensive drugs or in combination with a diuretic. Beta blockers are also used as antianginals and antidysrhythmics and are discussed in this context in Chapter 42.

BOX 44-1 COMBINATION OF THIAZIDES WITH ANTIHYPERTENSIVE DRUGS AND OTHER COMBINATIONS

Thiazide with Potassium-Sparing Diuretics

- hydrochlorothiazide with spironolactone (Aldactazide)
- hydrochlorothiazide with amiloride (Moduretic)
- hydrochlorothiazide with triamterene (Dyazide, Maxzide)

Thiazide with Beta Blockers

- hydrochlorothiazide with bisoprolol fumarate (Ziac)
- hydrochlorothiazide with metoprolol (Lopressor HCT)
- bendroflumethiazide with nadolol (Corzide)
- hydrochlorothiazide with propranolol (Inderide)
- hydrochlorothiazide with timolol (Timolide)
- chlorthalidone (thiazide-like diuretic) with atenolol (Tenoretic)

Thiazide with ACE Inhibitors

- hydrochlorothiazide with benazepril (Lotensin HCT)
- hydrochlorothiazide with captopril (Capozide)
- hydrochlorothiazide with enalapril maleate (Vaseretic)
- hydrochlorothiazide with fosinopril (Monopril HCT)
- hydrochlorothiazide with lisinopril (Prinzide, Zestoretic)
- hydrochlorothiazide with moexipril (Uniretic)
- hydrochlorothiazide with quinapril (Accuretic)

Thiazide with Angiotensin II Antagonists

- hydrochlorothiazide with candesartan (Atacand HCT)
- hydrochlorothiazide with eprosartan (Teveten HCT)
- hydrochlorothiazide with irbesartan (Avalide)
- hydrochlorothiazide with losartan (Hyzaar)
- hydrochlorothiazide with olmesartan medoxomil (Benicar HCT)
- hydrochlorothiazide with telmisartan (Micardis HCT)
- hydrochlorothiazide with valsartan (Diovan HCT)

Thiazide with Centrally Acting Alpha$_2$ Agonist

- chlorthalidone with clonidine (Combipres)
- hydrochlorothiazide with methyldopa (Aldoril)

Thiazide with Alpha Blocker

- polythiazide with prazosin (Minizide)

Combination of ACE Inhibitors with Calcium Channel Blocker

- See Table 44-3.

Combination of Calcium Channel Blocker with Statin Drug

- amlodipine with atorvastatin (Caduet)

ACE, Angiotensin-converting enzyme; *HCT,* hydrochlorothiazide.

Beta (β+ and β−)-adrenergic blockers reduce cardiac output by diminishing the sympathetic nervous system response to decrease basal sympathetic tone. With continued use of beta blockers, vascular resistance is diminished, and blood pressure is lowered. Beta blockers reduce heart rate, contractility, and renin release. There is a greater hypotensive response in patients with higher renin levels.

African-American hypertensive patients do not respond well to beta blockers alone for the control of hypertension. Instead, hypertension can be controlled by combining beta blockers with diuretics.

There are many types of beta blockers. Nonselective beta blockers, such as propranolol (Inderal) and carvedilol (Coreg) inhibit beta$_1$ (heart) and beta$_2$ (bronchial) receptors. Heart rate slows (blood pressure decreases secondary to the decrease in heart rate), and bronchoconstriction occurs because of unopposed parasympathetic tone. Cardioselective beta blockers are preferred, because they act mainly on the beta$_1$ rather than the beta$_2$ receptors and bronchoconstriction is less likely to occur. Acebutolol (Sectral), atenolol (Tenormin), betaxolol (Kerlone), bisoprolol (Zebeta), and metoprolol (Lopressor) are cardioselective beta blockers that block beta$_1$ receptors.

Cardioselectivity does not confer absolute protection from bronchoconstriction. In tests measuring forced expiratory volume in 1 second (FEV$_1$) as a measure of β− reactivity, only atenolol demonstrated true protection. Other cardioselective beta blockers were only partially effective. Studies also show that at the upper end of the dosage range, cardioselectivity is less effective. In patients with preexisting bronchospasm or other pulmonary disease, beta blockers, even those considered cardioselective, should be used with caution. Some experts regard this as a relative contraindication. The real value of beta selectivity is in maintaining renal blood flow and minimizing the hypoglycemic effects of beta blockade.

The combination of beta blockers with hydrochlorothiazides is packaged together in tablet form (see Box 44-1). Usually the hydrochlorothiazide dose is 12.5 to 25 mg, approximately half the average dose.

Beta blockers tend to be more effective in lowering blood pressure in patients who have an elevated serum renin level. The cardioselective prototype drug metoprolol (Lopressor) is presented in Prototype Drug Chart 44-1.

Beta blockers should not be used by patients with second- or third-degree atrioventricular (AV) block or sinus bradycardia. A noncardioselective beta blocker such as propranolol (Inderal) should not be given to a patient with chronic obstructive pulmonary disease (COPD).

Pharmacokinetics Metoprolol is well absorbed from the gastrointestinal tract. Its half-life is short and its protein-binding power is low.

Pharmacodynamics Cardioselective beta-adrenergic blockers block beta$_1$ receptors, thereby decreasing heart rate and blood pressure. The nonselective beta blockers block beta$_1$ and beta$_2$ receptors, which can result in bronchial constriction. Beta blockers cross the placental barrier and are excreted in breast milk.

The onset of action of oral beta blockers is usually 30 minutes or less, and the duration of action is 6 to 12 hours. When beta blockers are administered intravenously, the onset of action is immediate, peak time is 20 minutes (compared with 1.5 hours orally), and duration of action is 4 to 10 hours.

PROTOTYPE DRUG CHART 44-1

Metoprolol

Drug Class

Antihypertensive: beta$_1$ blocker
Trade Names: Lopressor, Toprol SR
Pregnancy Category: C; D (second and third trimester)

Dosage

Hypertension: A: PO: 50-100 mg/d in 1-2 divided doses; maint: 100-450 mg in divided doses; *max:* 450 mg/d in divided doses
C: >6 y: PO: 1 mg/kg/d; *max:* 2 mg/kg/d
SR: 50-100 mg/d; *max:* 400 mg/d
Myocardial infarction:
A: IV: 5 mg q2min × 3 doses; then 25-50 mg q6h for 48 h; maint: PO: 50-100 mg b.i.d.

Contraindications

Hypersensitivity, second- and third-degree heart block, cardiogenic shock, hypotension, acute HF, sinus bradycardia.
Caution: Hepatic, renal, or thyroid dysfunction; asthma; peripheral vascular disease; diabetes mellitus type 1

Drug-Lab-Food Interactions

Drug: Increase bradycardia with digitalis; increase hypotensive effect with other antihypertensives, alcohol, anesthetics; NSAIDs decrease effect of beta blockers
Lab: Increase in hepatic enzymes

Pharmacokinetics

Absorption: PO: 95%
Distribution: PB: 12%
Metabolism: $t\frac{1}{2}$: 3-7 h
Excretion: In urine

Pharmacodynamics

PO: Onset: 15 min
Peak: 1.5 h
Duration: 10-19 h
IV: Onset: Immediate
Peak: 20 min
Duration: 4-10 h

Therapeutic Effects/Uses

To control hypertension
Mode of Action: Promotes blood pressure reduction via beta$_1$-blocking effect

Side Effects

Fatigue, weakness, dizziness, nausea, vomiting, diarrhea, mental changes, drowsiness, headache, blurred vision, photosensitivity, nasal stuffiness, impotence, decreased libido, depression

Adverse Reactions

Bradycardia, thrombocytopenia, hypoglycemia, diabetes mellitus
Life-threatening: Complete heart block, bronchospasm, agranulocytosis

A, Adult; *b.i.d.,* twice a day; *d,* day; *h,* hour; *HF,* heart failure; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *SR,* sustained release; $t\frac{1}{2}$, half-life.

Side Effects and Adverse Reactions. Side effects and adverse reactions include decreased pulse rate, markedly decreased blood pressure, and (with noncardioselective beta$_1$ and beta$_2$ blockers) bronchospasm. Beta blockers should not be abruptly discontinued, because rebound hypertension, angina, dysrhythmias, and myocardial infarction can result. Beta blockers can cause dizziness, insomnia, depression, fatigue, nightmares, and sexual dysfunction. Other side effects are discussed in Chapter 42. Table 44-1 lists the beta blockers used to treat hypertension and their dosages, uses and considerations.

Noncardioselective beta blockers inhibit the liver's ability to convert glycogen to glucose in response to hypoglycemia. Because of this side effect, beta blockers should be used with caution in patients with diabetes mellitus. In addition, the depression of heart rate masks the symptom (tachycardia) of hypotension.

Nursing Process
Patient-Centered Collaborative Care

Antihypertensives: Beta Blockers

Assessment

- Obtain a medication and herbal history from patient. Report if a drug-drug or drug-herbal interaction is probable.
- Obtain vital signs. Report abnormal blood pressure and bradycardia. Compare vital signs with baseline finding.
- Check laboratory values related to renal and liver function periodically. Elevated blood urea nitrogen (BUN) and serum creatinine may be caused by beta blockers or cardiac disorder. Elevated cardiac enzymes, such as aspartate transaminase (AST) and lactate

TABLE 44-1 ANTIHYPERTENSIVES: BETA BLOCKERS AND CENTRAL ALPHA$_2$ AGONISTS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Beta-Adrenergic Blockers		
acebutolol HCl (Sectral) Cardioselective beta$_1$	A: PO: 400-800 mg/d in 1-2 divided doses; *max:* 1200 mg/d	For hypertension and cardiac dysrhythmia. Used alone or with a thiazide diuretic. Side effects include dizziness, fatigue, hypotension, bradycardia, and constipation/diarrhea. Closely monitor vital signs. Pregnancy category: B (D in second and third trimesters); PB: 10%-26%; t½: 3-13 h
atenolol (Tenormin) Cardioselective beta$_1$	A: PO: 25-100 mg/d; *max:* 100 mg/d Older adults: PO: 25-50 mg/d; *max:* 100 mg/d C: PO: 0.8-1.5 mg/kg/d; *max:* 2 mg/kg/d	For hypertension and angina. Similar side effects as acebutolol. Pregnancy category: D; PB: 5%-15%; t½: 6-7 h
betaxolol HCl (Kerlone, Betoptic-S) Cardioselective beta$_1$	Hypertension: A: PO: 5-20 mg/d; *max:* 20 mg/d Also used for glaucoma	For hypertension and glaucoma. Ophthalmic preparation used to decrease IOP. Pregnancy category: C; PB: 50%; t½: 15 h
bisoprolol fumarate (Zebeta) Beta$_1$ blocker	A: PO: Initially: 2.5-5 mg/d; *max:* 20 mg/d	For hypertension and angina pectoris. Long-acting beta$_1$ blocker. May decrease heart rate and blood pressure. Pregnancy category: C; PB: 30%-36%; t½: 9-12 h
carvedilol (Coreg) Alpha blocker Nonselective beta$_1$ and beta$_2$	A: PO: Initially: 6.25 mg, b.i.d. for 2 wk; *max:* 50 mg/d ER: A: PO: Initially: 20 mg/d; *max:* 80 mg/d	For treating hypertension and congestive heart failure. Food delays absorption. Pregnancy category: C (D in second and third trimesters); PB: 98%; t½: 7-10 h
metoprolol (Lopressor) Cardioselective beta$_1$	See Prototype Drug Chart 44-1.	
nadolol (Corgard) Nonselective beta$_1$ and beta$_2$	A: PO: 40-80 mg/d; *max:* 320 mg/d	For hypertension and angina pectoris. Similar to carteolol HCl. Pregnancy category: C; PB: 30%; t½: 10-24 h
penbutolol sulfate (Levatol) Nonselective beta$_1$ and beta$_2$	A: PO: 10-20 mg/d; *max:* 80 mg/d	Contraindicated in patients with asthma. Pregnancy category: C; PB: 80%-98%; t½: 5 h
pindolol (Visken) Nonselective beta$_1$ and beta$_2$	A: PO: 5 mg b.i.d.; *max:* 60 mg/d in divided doses	For hypertension and angina pectoris. Used alone or with a thiazide diuretic. Pregnancy category: B; PB: 40%-60%; t½: 3-4 h
propranolol (Inderal) Nonselective beta$_1$ and beta$_2$	A: PO: 40 mg b.i.d.; *max:* 640 mg/d SR: 80 mg/d; *max:* 640 mg/d	For hypertension, angina, and cardiac dysrhythmias. First beta blocker. May cause bronchospasm because of beta$_2$-blocker effect. Pregnancy category: C; PB: 90%; t½: 3-6 h
Central Alpha$_2$ Agonists		
clonidine HCl (Catapres)	A: PO: Initially: 0.1 mg b.i.d. or t.i.d.; *max:* 2.4 mg/d A: Transdermal patch: 0.1 mg/24 h q7d	For hypertension. Long duration of action. Well absorbed from GI tract. Used alone or with a thiazide diuretic. Decreases sympathetic effect. Drowsiness, dizziness, and dry mouth may occur. Pregnancy category: C; PB: 20%-40%; t½: 12-16 h
guanfacine HCl (Tenex)	A: PO: 1 mg/d h.s.; may increase to 2-3 mg/d; *max:* 4 mg/d	For hypertension. Long duration of action. Used alone or with a thiazide diuretic. Pregnancy category: B; PB: 70%; t½: 17 h
methyldopa	A: PO: 250 mg b.i.d.; *max:* 4 g/d IV: 250-1000 mg q6-8h; *max:* 4 g/d C: PO: 10 mg/kg/d in 2-4 divided doses	Used alone or with a thiazide diuretic. Can be given IV. Take with food if GI upset occurs. Pregnancy category: B; PB: 15%; t½: 1.7 h

A, Adult; *b.i.d.,* twice a day; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *h.s.,* at bedtime; *IOP,* intraocular pressure; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *SR,* sustained- release; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week; *>,* greater than; *<,* less than.

dehydrogenase (LDH), may be caused by beta blockers or cardiac disorder.

Nursing Diagnoses

- Decreased cardiac output related to variations in blood pressure readings
- Noncompliance with drug regimen related to cost of multiple drugs ordered
- Sexual dysfunction related to side effect of beta blockers
- Deficient knowledge related to inexperience with beta blockers

Planning

- Patient's blood pressure will be decreased or will return to normal value.
- Patient states he or she will take medication as prescribed.
- Patient will verbalize importance of following beta blocker regimen.

Nursing Interventions

- Monitor vital signs, especially blood pressure and pulse.
- Monitor laboratory results, especially BUN, serum creatinine, AST, and LDH.

Patient Teaching

General

- Encourage patient to comply with drug regimen. Abrupt discontinuation of antihypertensive drug may cause rebound hypertension.
- Inform patient that herbs can interfere with beta blockers (Herbal Alert 44-1).
- Advise that patient avoid OTC drugs without first checking with health care provider. Many OTC drugs carry warnings against use in presence of hypertension or concurrent use with antihypertensives.
- Suggest that patient wear a MedicAlert bracelet or carry card indicating health problem and prescribed drugs.
- Teach patient in trauma situation to inform health care provider of drugs taken daily (such as beta blocker). Beta blockers block compensatory effects of the body to the shock state. Glucagon may be needed to reverse effects so patient can be resuscitated.

Self-Administration

- Teach patient or family member how to take a radial pulse and blood pressure and to report abnormal findings to health care provider.

Side Effects

- Advise patient that antihypertensives may cause dizziness (orthostatic hypotension). Warn patient to rise slowly from lying or sitting to a standing position.
- Advise patient to report dizziness, slow pulse rate, changes in blood pressure, heart palpitation, confusion, or gastrointestinal upset to health care provider.
- Alert patient with diabetes mellitus to possible hypoglycemic symptoms.
- Inform patient that antihypertensives may cause sexual dysfunction (e.g., impotence).

Diet

- Teach patient and family members nonpharmacologic methods to decrease blood pressure, such as low-salt diet, relaxation techniques, exercise, smoking cessation, and decreased alcohol ingestion (1 to 2 oz daily).
- Advise patient to report constipation. Foods high in fiber, a stool softener, and increased water intake (except in patients with heart failure) are usually indicated.

Cultural Considerations

- Explain to African-American patients that monotherapy with beta blockers is generally less effective in controlling their hypertension. However, taking a diuretic together with a beta blocker can increase effectiveness of therapy.

Evaluation

- Evaluate effectiveness of drug therapy (decreased blood pressure, absence of side effects).
- Determine that patient adheres to drug regimen.

HERBAL ALERT 44-1

Antihypertensives

- Ma-huang and ephedra decrease or counteract the effect of antihypertensive drugs. When taken with beta blockers, hypertension may continue or increase.
- Ephedra increases hypertension when taken with beta blockers.
- Black cohosh increases the hypotensive effect of antihypertensive drugs.
- Hawthorn may increase the effects of beta blockers and angiotensin-converting enzyme inhibitors.
- Licorice antagonizes the effects of antihypertensive drugs.
- Goldenseal may increase the effects of antihypertensive drugs.
- Parsley may potentiate hypotension when taken with an antihypertensive drug.

Centrally Acting Alpha$_2$ Agonists

Centrally acting alpha$_2$ agonists decrease the sympathetic response from the brainstem to the peripheral vessels. They stimulate the alpha$_2$ receptors, which in turn decreases sympathetic activity; increases vagus activity; decreases cardiac output; and decreases serum epinephrine, norepinephrine, and renin release. All of these actions result in reduced peripheral vascular resistance and increased vasodilation. This group of drugs has minimal effects on cardiac output and blood flow to the kidneys. Beta blockers are not given with centrally acting sympatholytics, because accentuation of bradycardia during therapy and rebound hypertension on discontinuing therapy can occur.

Drugs in this group include methyldopa, clonidine, and guanfacine. Methyldopa was one of the first drugs widely used to control hypertension. In high doses, methyldopa and clonidine can cause sodium and water retention. Frequently methyldopa and clonidine are administered with diuretics. Clonidine is available in a transdermal preparation that provides a 7-day duration of action. Transdermal patches are replaced every 7 days and may be left on while bathing; skin irritations may occur. Guanfacine has effects similar to clonidine. Guanfacine has a long half-life and usually is taken once a day. Table 44-1 lists centrally acting alpha$_2$ agonists along with beta blockers.

Side Effects and Adverse Reactions. Side effects and adverse reactions of alpha$_2$ agonists include drowsiness, dry mouth, dizziness, and slow heart rate (bradycardia). Methyldopa should not be used in patients with impaired liver function, and serum liver enzymes should be monitored periodically in all patients. This group of drugs must not be abruptly discontinued, because a rebound hypertensive crisis can result. If the drug needs to be stopped immediately, another antihypertensive drug is usually prescribed to avoid rebound hypertensive symptoms (e.g., restlessness, tachycardia, tremors, headache, increased blood pressure). Rebound hypertension is less likely to occur with guanfacine. The nurse should emphasize the need to take the medication as prescribed. This group of drugs can cause sodium and water retention, resulting in peripheral edema. A diuretic may be ordered with methyldopa or clonidine to decrease water and sodium retention (edema). Patients who are pregnant or contemplating pregnancy should avoid clonidine. Methyldopa is frequently used to treat chronic or pregnancy-induced hypertension; however, it crosses the placental barrier, and small amounts may enter the breast milk of a lactating patient.

Alpha-Adrenergic Blockers

This group of drugs blocks the alpha-adrenergic receptors (alpha blockers), resulting in vasodilation and decreased blood pressure. They help maintain the renal blood flow rate. Alpha blockers are useful in treating hypertension in patients with lipid abnormalities. They decrease the very-low-density lipoproteins (VLDL) and the low-density lipoproteins (LDL) that are responsible for the buildup of fatty plaques in the arteries (atherosclerosis). In addition, they increase high-density lipoprotein (HDL) levels. Alpha blockers are safe for patients with diabetes, because they do not affect glucose metabolism. They also do not affect respiratory function.

The selective alpha$_1$-adrenergic blockers—prazosin, terazosin, and doxazosin—are used mainly to reduce blood pressure and can be used to treat benign prostatic hypertrophy. Prazosin is a commonly prescribed drug. Terazosin and doxazosin have longer half-lives than prazosin, and they are normally given once at bedtime. When prazosin is taken with alcohol or other antihypertensives, the hypotensive state can be intensified. These drugs, like the centrally acting alpha$_2$ agonists, cause sodium and water retention with edema; therefore, diuretics are frequently given concomitantly to decrease fluid accumulation in the extremities.

The more potent alpha blockers—phentolamine and phenoxybenzamine—are used primarily for hypertensive crisis and severe hypertension resulting from catecholamine-secreting tumors of the adrenal medulla (pheochromocytomas).

Pharmacokinetics Prazosin is absorbed through the GI tract, but a large portion of prazosin is lost during hepatic first-pass metabolism. The half-life is short, so the drug should be administered twice a day. Prazosin is highly protein-bound, and when it is given with other highly protein-bound drugs, the patient should be assessed for adverse reactions.

Pharmacodynamics Selective alpha-adrenergic blockers dilate the arterioles and venules, decreasing peripheral resistance and lowering blood pressure. With prazosin, the heart rate is only slightly increased, whereas with nonselective alpha blockers such as phentolamine, the blood pressure is greatly reduced, and reflex tachycardia can occur. Nonselective alpha blockers are more effective for acute hypertension; selective alpha blockers are more useful for long-term essential hypertension.

The onset of action of prazosin occurs between 30 minutes and 2 hours. The duration of action of prazosin is 10 hours. Table 44-2 presents drug data for selective and nonselective alpha blockers.

Side Effects and Adverse Reactions. Side effects of prazosin, doxazosin, and terazosin include orthostatic hypotension (dizziness, faintness, lightheadedness, and increased heart rate, which may occur with first dose), nausea, headache, drowsiness, nasal congestion caused by vasodilation, edema, and weight gain.

Side effects of phentolamine include hypotension, reflex tachycardia caused by the severe decrease in blood pressure, nasal congestion caused by vasodilation, and GI disturbances.

Drug Interactions. Drug interactions occur when alpha-adrenergic blockers are taken with antiinflammatory drugs and nitrates (e.g., nitroglycerin for angina). Peripheral edema is intensified when prazosin and an antiinflammatory drug are taken daily. Nitroglycerin taken for angina lowers blood pressure. If prazosin is taken with nitroglycerin, syncope (faintness) caused by a decrease in blood pressure can occur. The selective alpha-adrenergic blocker prazosin is shown in Prototype Drug Chart 44-2.

Adrenergic Neuron Blockers (Peripherally Acting Sympatholytics)

Adrenergic neuron blockers are potent antihypertensive drugs that block norepinephrine release from the sympathetic nerve endings, causing a decrease in norepinephrine release that results in a lowering of blood pressure. There is a decrease in both cardiac output and peripheral vascular resistance. Reserpine (the most potent drug) is used to control severe hypertension. Orthostatic hypotension is a common side effect, so the patient should be advised to rise slowly from a reclining or sitting position. The adrenergic neuron blockers are considered the last choices for treatment of chronic hypertension, because these drugs can cause orthostatic hypotension. Use of reserpine may cause vivid dreams, nightmares, and suicidal ideation. The drugs in this group can cause sodium and water retention. These drugs can be taken alone or with a diuretic to decrease peripheral edema.

Alpha$_1$- and Beta$_1$-Adrenergic Blockers

This group of drugs blocks both the alpha$_1$ and beta$_1$ receptors. Labetalol (Normodyne) is an example of an alpha/beta blocker. Blocking the alpha$_1$ receptor causes vasodilation, decreasing resistance to blood flow. The effect on the alpha receptor is stronger than the effect on the beta receptor;

TABLE 44-2 ANTIHYPERTENSIVES: SYMPATHOLYTICS: ALPHA ADRENERGIC AND PERIPHERALLY ACTING BLOCKERS AND DIRECT ACTING VASODILATORS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Selective Alpha-Adrenergic Blockers		
doxazosin mesylate (Cardura)	A: PO: Initially: 1 mg/d; *max:* 16 mg/d Older adults: PO: 0.5 mg/d	Used alone or with another antihypertensive. Orthostatic hypotension, headache, dizziness, and GI upset may occur. Pregnancy category: C; PB: 98%; t½: 22 h
prazosin HCl (Minipress)	See Prototype Drug Chart 44-2.	
terazosin HCl (Hytrin)	A: PO: Initially: 1 mg h.s.; *max:* 20 mg/d	Used alone or with another antihypertensive. Dizziness and headache may occur. Pregnancy category: C; PB: 90%-94%; t½: 9-12 h
Nonselective Alpha-Adrenergic Blockers		
phenoxybenzamine HCl (Dibenzyline)	A: PO: Initially: 10 mg b.i.d.; maint: 20-40 mg/d;	For hypertension related to adrenergic excess, pheochromocytoma. Lowers peripheral resistance. Long duration of action. Pregnancy category: C; PB: UK; t½: 24 h
phentolamine (OraVerse)	Pheochromocytoma: A: IM/IV: 2.5-5 mg; repeat 5-mg dose PRN; test is positive if decreased SBP >35 mm Hg and decreased DBP >25 mm Hg C: IV: 0.05-0.1 mg/kg; repeat with 5 mg PRN Extravasation: 5-10 mg in 10 mL NS local injection within 12 h	For diagnosis of pheochromocytoma and prevention of tissue necrosis after norepinephrine or epinephrine extravasation. Pregnancy category: C; PB: UK; t½: 20 min
Adrenergic Neuron Blockers (Peripherally Acting Sympatholytics)		
reserpine	A: PO: Initially: 0.5 mg/d for 1-2 wk; maint: 0.1-0.25 mg/d	For hypertension. Rarely used. May cause nightmares and vivid dreams. Pregnancy category: C; PB: 96%; t½: 50-100 h
Alpha$_1$- and Beta$_1$-Adrenergic Blockers		
labetalol HCl (Trandate)	Hypertension: A: PO: Initially: 100 mg b.i.d.; maint: 200-400 mg/d; *max:* 2.4 g/d Hypertensive emergency: A: IV: 20 mg over 2 min; continuous infusion: 1-2 mg/min; *max:* 300 mg/dose	For hypertension. Used alone or with a thiazide diuretic. May cause orthostatic hypotension, palpitations, and syncope. Pregnancy category: C; PB: 50%; t½: 6-8 h
Direct-Acting Vasodilators		
hydralazine HCl	A: PO: Initially: 10 mg q.i.d.; maint: 25-50 mg q.i.d. Severe hypertension: IM/IV: 10-40 mg, repeat PRN C: PO: 0.75-1 mg/kg/d divided q12h; max: 7.5 mg/kg/d q12h	For hypertension. Short duration of action. May be used with a diuretic to decrease edema and a beta blocker to prevent tachycardia. Dizziness, tremors, headaches, tachycardia, and palpitations may occur. Closely monitor vital signs. Pregnancy category: C; PB: 87%; t½: 2-8 h
minoxidil	A: PO: Initially: 5 mg/d; *max:* 100 mg/d C: PO: Initially: 0.2 mg/kg/d; *max:* 50 mg/d Alopecia: Topical: 2% sol b.i.d.	For hypertension. May be used with a diuretic to reduce edema and with a beta blocker to prevent tachycardia. Long duration of action. Do not discontinue drug abruptly; withdraw drug slowly to avoid rebound hypertension. Closely monitor vital signs. Pregnancy category: C; PB: 0%; t½: 4 h
sodium nitroprusside (Nipride, Nitropress)	Hypertensive emergency: A: IV: 0.25-5 mcg/kg/min in D_5W; *max:* 10 mcg/kg/min	For hypertensive crisis. Potent antihypertensive. Drug decomposes in light; container must be wrapped in aluminum foil. Good for 24 h. Discard drug if red or blue. Cyanide toxicity may occur. Measure cyanide and thiocyanate levels. May cause profound hypotension. Pregnancy category: C; PB: UK; t½: 2 min

A, Adult; *b.i.d.,* twice a day; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *h.s.,* at bedtime; *IM,* intramuscular; *IV,* intravenous; *maint,* maintenance; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *min,* minute; *NB,* newborn; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *q.i.d.,* four times a day; *sec,* second; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week.

PROTOTYPE DRUG CHART 44-2

Prazosin HCl

Drug Class Antihypertensive: alpha-adrenergic blocker Trade Name: Minipress Pregnancy Category: C	**Dosage** A: PO: 1 mg b.i.d./t.i.d.; maint: 3-15 mg/d; *max:* 20 mg/d in divided doses
Contraindications Renal disease Caution: Angina	**Drug-Lab-Food Interactions** Drug: Increased hypotensive effect with other antihypertensives, nitrates, alcohol Lab: Increased hepatic enzymes
Pharmacokinetics Absorption: GI: 60% (5% to circulation) Distribution: PB: 95% Metabolism: t½: 3 h Excretion: In bile and feces; 10% in urine	**Pharmacodynamics** PO: Onset: 0.5-2 h Peak: 2-4 h Duration: 10 h
Therapeutic Effects/Uses To control hypertension, refractory HF; to treat benign prostatic hypertrophy Mode of Action: Dilates peripheral blood vessels by blocking alpha-adrenergic receptors	
Side Effects Dizziness, drowsiness, vertigo, blurred vision, tinnitus, fatigue, headache, depression, nasal congestion, dry mouth, nausea, vomiting, diarrhea, abdominal pain, impotence, urinary incontinence	**Adverse Reactions** Orthostatic hypotension, palpitations, bradycardia, tachycardia, pancreatitis

A, Adult; *b.i.d.,* twice a day; *d,* day; *h,* hour; *HF,* heart failure; *GI,* gastrointestinal; *maint,* maintenance; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *t ½,* half-life; *t.i.d.,* three times a day.

therefore blood pressure is lowered and pulse rate is moderately decreased. By blocking the cardiac beta$_1$ receptor, both heart rate and atrioventricular (AV) contractility are decreased. Large doses of alpha/beta blockers could block beta$_2$-adrenergic receptors, thus increasing airway resistance. Patients who have severe asthma should not take large doses of labetalol. Table 44-2 lists two alpha/beta blockers.

Nursing Process
Patient-Centered Collaborative Care

Antihypertensives: Alpha-Adrenergic Blockers

Assessment

- Obtain a medication history from patient, including current drugs. Report if drug-drug or drug-herbal interaction is probable. Prazosin is highly protein-bound and can displace other highly protein-bound drugs.
- Obtain baseline vital signs and weight for future comparison.
- Check urinary output. Report if it is decreased (less than 600 mL/day), because drug is contraindicated if renal disease is present.

Nursing Diagnoses

- Risk for activity intolerance related to drug regimen and/or cardiac status
- Deficient knowledge related to drug regimen
- Ineffective sexuality pattern related to beta-blocker or other drug therapy

Planning

- Patient's blood pressure will decrease.
- Patient will follow proper drug regimen.

Nursing Interventions

- Monitor vital signs. Desired therapeutic effect of prazosin may not fully occur for 4 weeks. Sudden marked decrease in blood pressure and tachycardia should be reported.
- Check daily for fluid retention in extremities and weight gain. Prazosin may cause sodium and water retention.

Patient Teaching

General

- Advise patient to comply with drug regimen. Abrupt discontinuation of antihypertensive drug may cause rebound hypertension.
- Inform patient that orthostatic hypotension may occur. Explain that before rising, patient should sit and dangle

feet. Drug may be taken at bedtime to avoid orthostatic hypotension.

- Teach patient to self-monitor daily weights. Prazosin may lead to edema.

Self-Administration

- Teach patient or family member how to take and record blood pressure. A blood pressure chart should be established, and blood pressure changes should be reported.

Side Effects

- Caution patient that dizziness, lightheadedness, and drowsiness may occur, especially when drug is first prescribed. If these symptoms occur, health care provider should be notified.
- Inform male patient that impotence may occur if high doses of drug are prescribed. This problem should be reported to the health care provider.
- Tell patient to report if edema is present in the morning. Water retention is a problem with alpha blockers.
- Inform patient not to take cold, cough, or allergy OTC medications without first contacting the health care provider.

Diet

- Encourage patient to decrease salt intake unless otherwise indicated by the health care provider.

Cultural Considerations

- Explain to African-American patients with hypertension that they can take alpha-adrenergic blockers and calcium channel blockers but should avoid taking beta blockers, because these agents are not generally effective in controlling their hypertension. However, taking a diuretic together with a beta blocker increases effectiveness for these patients.
- Caution Asian patients that they are twice as sensitive to effects of propranolol on the blood pressure and heart rate, so dose should be decreased or another antihypertensive drug may be given.

Evaluation

- Evaluate effectiveness of drug in controlling blood pressure; side effects should be absent.
- Evaluate patient's adherence to medication schedule.
- Evaluate patient's knowledge of medication.

Common side effects of these drugs include orthostatic hypotension, GI disturbances, nervousness, dry mouth, and fatigue. Large doses of labetalol may cause AV heart block.

Direct-Acting Arteriolar Vasodilators

Vasodilators are potent antihypertensive drugs. Direct-acting vasodilators act by relaxing the smooth muscles of the blood vessels, mainly the arteries, causing vasodilation. Vasodilators promote an increase in blood flow to the brain and kidneys. With vasodilation, the blood pressure decreases and sodium and water are retained, resulting in peripheral edema. Diuretics can be given with a direct-acting vasodilator to decrease the edema.

Two direct-acting vasodilators, hydralazine and minoxidil, are used for moderate to severe (dose-related) hypertension. These two drugs cause little orthostatic hypotension, because of minimum dilation of the arterioles. However, reflex tachycardia and release of renin can occur secondary to vasodilation and decreased blood pressure. Beta blockers are frequently prescribed with arteriolar vasodilators to decrease the heart rate; this counteracts the effect of reflex tachycardia.

Nitroprusside is prescribed for acute hypertensive emergency. This is a very potent vasodilator that rapidly decreases blood pressure. Nitroprusside acts on both arterial and venous vessels. Table 44-2 lists direct-acting vasodilators.

Side Effects and Adverse Reactions

The effects of hydralazine are numerous and include reflex tachycardia, palpitations, edema, nasal congestion, headache, dizziness, GI bleeding, lupus-like symptoms, and neurologic symptoms (tingling, numbness). Minoxidil has similar side effects, as well as tachycardia, edema, and excess hair growth. It can precipitate an anginal attack.

Nitroprusside can cause reflex tachycardia, palpitations, restlessness, agitation, nausea, and confusion. Nitroprusside is discussed in greater detail in Chapter 59.

Angiotensin-Converting Enzyme Inhibitors

ACE inhibitors inhibit ACE, which in turn inhibits the formation of angiotensin II (vasoconstrictor) and blocks the release of aldosterone. Aldosterone promotes sodium retention and potassium excretion. When aldosterone is blocked, sodium is excreted along with water, and potassium is retained. ACE inhibitors cause little change in cardiac output or heart rate, and they lower peripheral resistance. (Figure 44-1 illustrates the RAAS.) These drugs can be used in patients who have elevated serum renin levels.

The ACE inhibitors are used primarily to treat hypertension; some of these agents are also effective in treating heart failure. The ACE inhibitors are benazepril (Lotensin), captopril (Capoten), enalapril maleate (Vasotec), fosinopril (Monopril), lisinopril (Prinivil, Zestril), moexipril (Univasc), perindopril (Aceon), quinapril (Accupril), ramipril (Altace), and trandolapril (Mavik), which are all presented in Table 44-3. These drugs can be used for first-line antihypertensive therapy, but thiazide diuretics are recommended by JNC 7.

African Americans and older adults do not respond to ACE inhibitors with the desired reduction in blood pressure, but when taken with a diuretic, blood pressure usually will be lowered. ACE inhibitors should not be given during pregnancy, because they reduce placental blood flow. For patients with renal insufficiency, reduction of the drug dose (except for fosinopril), is necessary.

TABLE 44-3 ANTIHYPERTENSIVES: ACE INHIBITORS AND ANGIOTENSIN II RECEPTOR BLOCKERS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Angiotensin Antagonists (ACE Inhibitors)		
benazepril HCl (Lotensin)	A: PO: 10-40 mg/d in 1-2 divided doses; *max:* 80 mg/d	Headache, dizziness, hypotension, nausea, diarrhea, or constipation may occur. Pregnancy category: D; PB: 97%; $t_{1/2}$: 10 h
captopril (Capoten)	A: PO: Initially: 12.5-25 mg, b.i.d./t.i.d.; maint: 25-150 mg, b.i.d./t.i.d.; *max:* 450 mg/d	For hypertension and HF. Inhibits conversion of angiotensin I to angiotensin II. Irritating cough may occur; retains potassium. Pregnancy category: C and D; PB: 25%-30%; $t_{1/2}$: 2-3 h
enalapril maleate (Vasotec); enalaprilat (Vasotec I.V.)	A: PO: Initially: 2.5-5 mg/d; maint: 10-40 mg/d Hypertensive emergencies: IV: 1.25-5 mg over 5 min q6h PRN	For hypertension and HF. Similar to captopril and benazepril. Give IV slowly over at least 5 min. Pregnancy category: C and D; PB: 50%-60%; $t_{1/2}$: 2-11 h
fosinopril (Monopril)	A: PO: 5-40 mg/d; *max:* 80 mg/d	For hypertension and HF. Reduces peripheral resistance (afterload) and improves cardiac output. Dose does not need to be reduced because of renal insufficiency. Pregnancy category: D; PB: 97%; $t_{1/2}$: 12 h
lisinopril (Prinivil, Zestril)	A: PO: Initially: 10 mg/d; maint: 20-40 mg/d; *max:* 80 mg/d	For hypertension and HF. Usually given with a diuretic. Long duration of action (24 h). Monitor vital signs. Pregnancy category: D; PB: 25%; $t_{1/2}$: 12 h
moexipril (Univasc)	A: PO: 7.5 mg/d; *max:* 30 mg/d in divided doses	For hypertension. May increase serum lithium levels and cause toxicity. Pregnancy category: C and D; PB: 50%; $t_{1/2}$: 2-9 h
perindopril (Aceon)	A: PO: 4-8 mg/d; *max:* 16 mg/d	For mild to moderate hypertension. Reduces vasoconstriction. Cough may occur. Pregnancy category: D; PB: 10%-60%; $t_{1/2}$: 1-10 h
quinapril HCl (Accupril)	A: PO: 10-20 mg/d; *max:* 80 mg/d in divided doses Older adults: A: PO: Initially 2.5-5 mg/d	For hypertension and HF. Potent ACE inhibitor. Reduces systemic vascular resistance and increases cardiac output. Pregnancy category: C and D; PB: 97%; $t_{1/2}$: 24 h
ramipril (Altace)	A: PO: 2.5-5 mg/d; *max:* 20 mg/d	For hypertension and HF. Similar to captopril. Long duration of action (24 hours). Pregnancy category: C and D; PB: 73%; $t_{1/2}$: 2-3 h
trandolapril (Mavik)	A: PO: 1-2 mg/d; may increase weekly to 2-4 mg/d; *max:* 8 mg/d	For hypertension. May be used alone or with another antihypertensive. African Americans respond to trandolapril, including those with low-renin hypertension. Pregnancy category: C and D; PB: 80%; $t_{1/2}$: 6-10 h
Combinations of ACE Inhibitors with Calcium Blockers		
benazepril with amlodipine (Lotrel)	A: PO: amlodipine/benazepril 2.5/10 mg/d; 5/10 mg/d; 5/20 mg/d	For hypertension
trandolapril with verapamil (Tarka)	A: PO: trandolapril/verapamil SR: 2/180 mg/d; 1/240 mg/d; 2/240 mg/d; 4/240 mg/d	For hypertension
Angiotensin II Receptor Blockers (ARBs)		
candesartan (Atacand)	A: PO: 16 mg/d; maint: 8-32 mg/d	For hypertension and HF. May be used when patient does not respond to or tolerate ACE inhibitors. May be combined with calcium blocker amlodipine for more effective response in decreasing high blood pressure. Pregnancy category: C and D; PB: 99%; $t_{1/2}$: 9 h
eprosartan (Teveten)	A: PO: Initially: 600 mg/d; maint: 400-800 mg/d; *max:* 900 mg/d	For mild to moderate hypertension. Does not cause irritating cough associated with ACE inhibitors. Food can cause slight delay in drug absorption. Pregnancy category: C and D; PB: 98%; $t_{1/2}$: 5-9 h
irbesartan (Avapro)	A: PO: 150 mg/d; maint: 150-300 mg/d	For hypertension. May be used alone or with other antihypertensives. Pregnancy category: C and D; PB: 90%; $t_{1/2}$: 11-15 h
losartan potassium (Cozaar)	A: PO: 25-50 mg/d, in 1-2 divided doses; *max:* 100 mg/d	For hypertension. May be used alone or with other antihypertensives. Pregnancy category: C and D; PB: 98%; $t_{1/2}$: 2 h
olmesartan medoxomil (Benicar)	A: PO: 20 mg/d; may increase to 40 mg/d	Inhibits binding angiotensin II to AT_1 receptors. Promotes vasodilation, and decreases peripheral resistance. Not recommended if patient is volume-depleted. Pregnancy category: C and D; PB: 99%; $t_{1/2}$: 13 h
telmisartan (Micardis)	A: PO: 40-80 mg/d	For mild to moderate hypertension. Does not cause cough associated with ACE inhibitors. Angioedema rarely occurs. Pregnancy category: C and D; PB: 99.5%; $t_{1/2}$: 24 h
valsartan (Diovan)	See Prototype Drug Chart 44-3.	
azilsartan (Edarbi)	A: PO: 40-80 mg/d; *max:* 80 mg/d	For hypertension as monotherapy or with other antihypertensives. Minimal adverse effects of diarrhea, orthostatic hypotension. Pregnancy category: C and D; PB: 99%; $t_{1/2}$: 11 h

TABLE 44-3 ANTIHYPERTENSIVES: ACE INHIBITORS AND ANGIOTENSIN II RECEPTOR BLOCKERS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Aldosterone Receptor Antagonists		
eplerenone (Inspra)	A: PO: 50 mg/d; may increase to 50 mg b.i.d.	Binds aldosterone at mineralocorticoid receptor. Contraindications: serum potassium >5.5 mEq/L, creatinine clearance <50 mL/min, type 2 diabetes, and taking potassium-sparing diuretics. For hypertension, HF, and postmyocardial infarction. Pregnancy category: B; PB: 50%; t½: 4-6 h
Direct Renin Inhibitors		
aliskiren (Tekturna)	A: PO: 150-300 mg/d	First direct renin inhibitor for mild to moderate hypertension. Used either as monotherapy or with antihypertensive such as an ARB valsartan (Diovan). Hyperkalemia uncommon for monotherapy. Pregnancy category: C and D; PB: 49%; t½: 24 h

A, Adult; *ACE,* angiotensin-converting enzyme; *ARB,* angiotensin II receptor blocker; AT_1, angiotensin I; *b.i.d.,* two times a day; *d,* day; *ER,* extended-release; *h,* hour; *HF,* heart failure; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *>,* greater than; *<,* less than.

With the exception of moexipril, which should be taken on an empty stomach for maximum effectiveness, ACE inhibitors can be administered with food.

Side Effects and Adverse Reactions. The primary side effect of ACE inhibitors is a constant, irritated cough. Other side effects include nausea, vomiting, diarrhea, headache, dizziness, fatigue, insomnia, serum potassium excess (hyperkalemia), and tachycardia. The persistent, nonproductive "ACE cough" may be relieved upon discontinuance of the drug. Often an ARB may be substituted without cough as a side effect. The major adverse effects are first-dose hypotension and hyperkalemia. Hypotension results because of the vasodilating effect. First-dose hypotension is more common in patients also taking diuretics. Angioedema (swelling of face, tongue, lips, mucous membranes, larynx, and extremity edema) may occur due to hypersensitivity and has a higher incidence in African Americans. This may occur within hours or 1 week after the first dose. Angioedema may be reversed with drug discontinuance. When laryngeal edema occurs, the patient may require rescue epinephrine.

Contraindications. ACE inhibitors should not be given during pregnancy; harm to the fetus due to reduction in placental blood flow could occur. This group of drugs should not be taken with potassium-sparing diuretics such as spironolactone (Aldactone) or salt substitutes that contain potassium, because of the risk of hyperkalemia (serum potassium excess).

Nursing Process
Patient-Centered Collaborative Care

Antihypertensives: Angiotensin-Converting Enzyme Inhibitors

Assessment

- Obtain a drug and herbal history from patient of current drugs taken. Report if drug-drug or drug-herbal interaction is probable.
- Obtain baseline vital signs for future comparisons.
- Check laboratory values for serum protein, albumin, blood urea nitrogen (BUN), creatinine, potassium, and white blood cell count, and compare with future serum levels.

Nursing Diagnoses

- Deficient knowledge related to drug regimen
- Anxiety related to hypertensive state
- Risk for falls related to orthostatic hypotension

Planning

- Patient's blood pressure will be within desired range.
- Patient will be free from moderate to severe side effects. Angioedema, cough, dysgeusia, weakness, hyperkalemia, orthostatic hypotension, and renal impairment may occur as side effects.

Nursing Interventions

- Monitor blood pressure. A sudden drop in blood pressure should be reported.
- Monitor laboratory tests related to renal function (BUN, creatinine, protein) and blood glucose levels. Caution: Watch for hypoglycemic reaction in patients with diabetes mellitus. Urine protein may be checked in the morning using a dipstick.
- Report to health care provider occurrences of bruising, petechiae, and/or bleeding. These may indicate a severe adverse reaction to an angiotensin antagonist such as captopril.

Patient Teaching

General

- Warn patient not to abruptly discontinue use of captopril without notifying health care provider. Rebound hypertension could result.

- Inform patient not to take OTC drugs (e.g., cold medication) without first contacting health care provider.
- Advise patient not to use salt substitute with potassium.
- Warn patient who is pregnant or contemplating becoming pregnant not to take ACE inhibitors or ARBs; they can cause harm to the fetus.
- Teach patient to rise slowly to avoid orthostatic hypotension.

Self-Administration

- Teach patient or family member how to take and record blood pressure. A blood pressure chart should be established, and blood pressure changes should be reported.

Side Effects

- Explain to patient that dizziness and/or lightheadedness may occur during the first week of captopril therapy. If dizziness persists, health care provider should be notified.
- Advise patient to report any occurrence of bleeding.

Diet

- Teach patient to take captopril 20 minutes to 1 hour before a meal. Food decreases 35% of captopril absorption.
- Warn patient that taste of food may be diminished during first month of drug therapy.
- Advise patient to avoid foods high in potassium because hyperkalemia is an adverse effect of ACE inhibitors.

Cultural Considerations

- Explain to African-American patients that they may not respond well to ACE inhibitors unless the drug is taken with a diuretic.

Evaluation

- Evaluate effectiveness of drug therapy (absence of severe side effects, blood pressure return to desired range).
- Evaluate patient's renal function.

Angiotensin II Receptor Blockers

Angiotensin II receptor blockers (ARBs) are similar to ACE inhibitors in that they prevent the release of aldosterone (sodium-retaining hormone). They act on the renin-angiotensin-aldosterone system (RAAS). The difference between ARBs and ACE inhibitors is that ARBs block angiotensin II from the angiotensin I (AT_1) receptors found in many tissues, whereas ACE inhibitors inhibit the angiotensin-converting enzyme in the formation of angiotensin II. ARBs cause vasodilation and decrease peripheral resistance. They do not cause the constant, irritated cough ACE inhibitors can. Like ACE inhibitors, ARBs should not be taken during pregnancy.

Losartan (Cozaar), valsartan (Diovan), irbesartan (Avapro), candesartan cilexetil (Atacand), eprosartan (Teveten), olmesartan medoxomil (Benicar), and telmisartan (Micardis) are examples of ARBs. These agents block the vasoconstrictor effects of angiotensin II at the receptor site. The combination of losartan potassium and hydrochlorothiazide tablets and valsartan and hydrochlorothiazide tablets and others should not cause serum potassium excess or loss. ARBs may be used as a first-line treatment for hypertension.

Prototype Drug Chart 44-3 gives the pharmacologic data related to valsartan.

SAFETY: Preventing Medication Errors

Do not confuse…

- **Diovan** and **Dioval.** Diovan (valsartan) is an angiotensin II receptor blocker. Dioval is an estradiol, an estrogen hormone. If both drugs are in the home, caution must be taken to select the correct drug, especially by the male patient taking Diovan and the female patient taking Dioval.

Pharmacokinetics Valsartan is prescribed primarily to manage hypertension. The combination drug Diovan HCT contains valsartan plus a low dose of hydrochlorothiazide. It is rapidly absorbed in the GI tract and undergoes first-pass metabolism in the liver to form active metabolites. It is highly protein-bound and should not be given during pregnancy, especially during the second and third trimester. The half-life is 6 to 9 hours. The drug is excreted in urine and feces.

Pharmacodynamics Valsartan is a potent vasodilator. It blocks the binding of angiotensin II to the AT_1 receptors found in many tissues. Its peak time is 4 to 6 hours, and it has a long duration of action: 24 hours.

Like ACE inhibitors, ARBs are less effective for treating hypertension in African-American patients. In addition, like ACE inhibitors, ARBs may cause angioedema. These agents can be taken with or without food and are suitable for patients with mild hepatic insufficiency.

Direct Renin Inhibitor

The first FDA-approved direct renin inhibitor for treating hypertension is aliskiren (Tekturna). Aliskiren binds with renin, causing a reduction of angiotensin I, angiotensin II, and aldosterone levels (see Figure 44-1). It is effective for mild and moderate hypertension. Aliskiren can be used alone or with another antihypertensive agent. It has an additive effect in reducing blood pressure when combined with a thiazide diuretic or an ARB.

This drug, when used as monotherapy, has not proven to be as effective in reducing blood pressure in the African-American population.

Calcium Channel Blockers

Slow calcium channels are found in the myocardium (heart muscle) and vascular smooth muscle (VSM) cells. Free calcium increases muscle contractility, peripheral resistance, and blood pressure. Calcium channel blockers, also called *calcium antagonists* and *calcium blockers,* block the calcium channel in the VSM, promoting vasodilation. The large central arteries are not as sensitive to calcium blockers as coronary and cerebral arteries and the peripheral vessels. Calcium blockers are highly protein-bound but have a short

PROTOTYPE DRUG CHART 44-3

Valsartan

Drug Class Antihypertensive: angiotensin II receptor blocker Trade Names: Diovan Pregnancy Category: C (first trimester); D (second and third trimesters)	**Dosage** Hypertension: A: PO: Initially 80-160 mg/d; maint: 80-320 mg/d; *max:* 320 mg/d C: >6 y: PO: Initially 1.3 m/kg/d; *max:* 2.7 mg/kg/d
Contraindications Hypersensitivity, pregnancy, breastfeeding Caution: Renal and hepatic impairments, hypotension, hypovolemia, hyperkalemia	**Drug-Lab-Food Interactions** Drug: Antihypertensives, diuretics, MAOIs, alcohol may increase hypotensive effects; ACE inhibitors and aspirin may increase hyperkalemia and renal dysfunction; digoxin, NSAIDs may increase renal dysfunction; lithium may increase lithium toxicity Lab: May increase AST, ALT, ALP, bilirubin, BUN, creatinine, Hct, Hgb
Pharmacokinetics Absorption: Rapidly absorbed, 25-30 in blood circulation Distribution: PB: 94%-95% Metabolism: $t_{1/2}$: 6-9 h Excretion: 13% in urine and 83% in bile/feces	**Pharmacodynamics** PO: Onset: 2 h Peak: 4-6 h Duration: 24 h
Therapeutic Effects/Uses To treat hypertension Mode of Action: Potent vasodilator; inhibits binding of angiotensin II	
Side Effects Dizziness, drowsiness, cough (rare), blurred vision, headache, diarrhea, insomnia, arthralgia, fatigue	**Adverse Reactions** Orthostatic hypotension, hypoglycemia, hyperkalemia Life threatening: renal dysfunction

A, Adult; *ALP,* alkaline phosphatase; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *BUN,* blood urea nitrogen; *C,* child; *d,* day; *h,* hour; *Hct,* hematocrit; *Hgb,* hemoglobin; *max,* maximum; *PO,* by mouth; *PB,* protein-binding; $t_{1/2}$, half-life.

half-life. Slow-release preparations decrease frequency of administration. Table 44-4 lists the calcium blockers in three groups: diphenylalkylamine (verapamil), benzothiazepines (diltiazem), and dihydropyridine (amlodipine and others).

Verapamil (Calan) is used to treat chronic hypertension, angina pectoris, and cardiac dysrhythmias. Verapamil and diltiazem act on the arterioles and the heart. The dihydropyridines are the largest group of calcium channel blockers and consist of seven drugs; six of these are used to control hypertension. The calcium blocker nimodipine is used to prevent ischemic brain injury due to vasospasm that often accompanies subarachnoid hemorrhage.

Nifedipine (Procardia) decreases blood pressure in older adults and in those with low serum renin values. Nifedipine and verapamil are potent calcium blockers. Nifedipine, in its immediate-release form (10- and 20-mg capsules), has been associated with an increased incidence of sudden cardiac death, especially when prescribed for outpatients at high doses. This is not true of the sustained-release preparations (Procardia XL, Adalat CC). For this reason, immediate-release nifedipine is usually prescribed for acute rises in blood pressure only on an as-needed basis in the hospital setting. Like the vasodilators, calcium channel blockers can cause reflex tachycardia; it is more prevalent with nifedipine.

Pharmacokinetics Amlodipine (Norvasc), like other calcium blockers, is highly protein-bound. It is gradually absorbed via the GI tract. Because the half-life of amlodipine is longer than that of other calcium blockers, it is taken once a day.

Pharmacodynamics Amlodipine may be used alone or with other antihypertensive drugs. Peripheral edema may occur because of its vasodilator effect, so persons with edema may need to take another type of antihypertensive drug. This drug has a long duration of action, so it is prescribed only once a day. Amlodipine may be combined with the ACE inhibitor benazepril, forming Lotrel.

Normally beta blockers are not prescribed with calcium blockers, because both drugs decrease myocardium contractility. Calcium blockers lower blood pressure better in African Americans than drugs in other categories.

Side Effects and Adverse Reactions. The side effects and adverse reactions of calcium channel blockers include flushing, headache, dizziness, ankle edema, bradycardia, and AV block.

TABLE 44-4 ANTIHYPERTENSIVES: CALCIUM CHANNEL BLOCKERS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Phenylalkylamines		
verapamil (Calan SR, Isoptin SR)	A: PO: 40-80 mg t.i.d. A: PO: SR: 90-240 mg/d in 2 divided doses; *max:* 480 mg/d	For hypertension (SR form). One of first calcium blockers. Also used for variant angina and cardiac dysrhythmias. Dizziness, headache, hypotension, bradycardia, and constipation may occur. Pregnancy category: C; PB: 94%; t½: 3-8 h
Benzothiazepines		
diltiazem HCl (Cardizem CD, Tiazac)	A: PO SR: Initially: 120-240 mg/d; *max:* 540 mg/d	For hypertension (SR form) and angina pectoris; IV form for cardiac dysrhythmias (atrial fibrillation). Headache, bradycardia, and hypotension may occur. Pregnancy category: C; PB: 75%; t½: 3-8 h
Dihydropyridines		
amlodipine (Norvasc)	A: PO: 5-10 mg/d. Older adults: 2.5-5.0 mg/d; maint: 5-10 mg/d	For mild to moderate hypertension and angina pectoris. Decreases peripheral vascular resistance (vasodilation). Used alone or with other antihypertensives. Pregnancy category: C; PB: 95%; t½: 30-50 h
felodipine (Felendil XL)	A: PO: Initially: 2.5-5 mg/d; *max:* 10 mg/d	For hypertension, HF, and angina pectoris. Potent calcium blocker. Flushing, peripheral edema, palpitations, dizziness, and headache may occur. Long duration of action. Pregnancy category: C; PB: 99%; t½: 10-16 h
isradipine (DynaCirc CR)	Hypertension: A: PO: 2.5 mg b.i.d.; *max:* 20 mg/d Older adults: 2.5 mg b.i.d.; *max:* 10 mg/d	For management of hypertension, HF, and angina pectoris. Used alone or with a diuretic. Pregnancy category: C; PB: 95%-97%; t½: 5-11 h
nicardipine HCl (Cardene SR)	A: PO: 20-40 mg t.i.d. SR: 30-60 mg b.i.d. ER: A: PO: 30-60 mg b.i.d. A: IV: initially: 5 mg/h; *max:* 15 mg/h	For essential hypertension and vasospastic angina. IV therapy for short-term hypertension therapy. Decreases systemic resistance; heart rate and cardiac output increased. Pregnancy category: C; PB: 95%; t½: 2-4 h
nifedipine (Procardia XL, Adalat CC)	A: PO: XL: 30-60 mg once daily; *max:* Adalat CC: 90 mg/d; Procardia XL: 120 mg/d	For hypertension and angina pectoris. Potent calcium channel blocker. Dizziness, lightheadedness, headache, flushing, peripheral edema, and nausea may occur. May be taken alone or with a diuretic. Pregnancy category: C; PB: 92%-98%; t½: 2-5 h
nisoldipine (Sular)	A: PO: 17-20 mg/d in 2 divided doses; *max:* old Sular formulation: 60 mg/d; newer Sular formulation: 34 mg/d	For hypertension and angina pectoris. May be used alone or with another antihypertensive. Like nifedipine, causes vasodilation, but 10 times more potent than nifedipine. Considered a potent coronary vasodilator. Pregnancy category: C; PB: 99%; t½: 7-12 h

A, Adult; *b.i.d.,* twice a day; *C,* child; *ER,* extended-release; *HF,* heart failure; *d,* day; *h,* hour; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *SR,* sustained-release; *t½,* half-life; *t.i.d.,* three times a day; *>,* greater than.

CRITICAL THINKING CASE STUDY

GG, a 72-year-old African-American patient, has heart failure and diabetes. Her vital signs are blood pressure 176/94, pulse 92, and respirations 30. Her medications include hydrochlorothiazide 50 mg/day, atenolol 50 mg/day, and digoxin 0.25 mg/day.

1. Why was hydrochlorothiazide prescribed for GG? Explain the effects of hydrochlorothiazide on blood pressure.
2. Abnormal electrolytes and other laboratory test results may occur when taking hydrochlorothiazide. Would the following serum electrolyte and laboratory values be expected to *increase* or *decrease?*
   a. Sodium
   b. Potassium
   c. Calcium
   d. Magnesium
   e. Glucose
   f. Uric acid
3. Why should GG's blood glucose level be monitored while she is taking hydrochlorothiazide?
4. What effect may result when GG takes digoxin and hydrochlorothiazide together? Explain your answer.
5. Atenolol is what type of antihypertensive? Would atenolol be effective in lowering GG's blood pressure if given as the only antihypertensive drug? Explain your answer.
6. How effective is the combination of hydrochlorothiazide and atenolol for controlling GG's blood pressure? Explain your answer.

7. When using a combination drug therapy to correct hypertension, would the dosage for each drug be the same? Explain your answer.
8. When abruptly discontinuing beta blockers for hypertension without the patient taking another antihypertensive, what might occur? Explain how adverse effects can be avoided.

GG's blood glucose is 229. Her drugs for controlling hypertension are changed to prazosin 10 mg t.i.d. Her cholesterol and LDL are elevated. Her serum potassium level is 3.2 mEq/L.

9. Why were GG's hydrochlorothiazide and atenolol discontinued? Explain your answer.
10. What type of antihypertensive is prazosin? Explain the physiologic action of prazosin for lowering the blood pressure.
11. Does prazosin have an effect on the blood glucose level? What effect could prazosin have on GG's abnormal lipid levels? Explain your answer.

GG's ankles have become edematous. Hydrochlorothiazide is prescribed.

12. Why was hydrochlorothiazide added again to the drug regimen?
13. Is the daily prazosin dose within the safe therapeutic prescribed range for GG? Explain your answer. (You may refer to Prototype Drug Chart 44-2.)
14. List the groups of antihypertensive drugs that can cause sodium and water retention.

NCLEX STUDY QUESTIONS

1. A patient's blood pressure (BP) is 130/84. The health care provider plans to suggest nonpharmacologic methods for the patient. Which should the nurse include in teaching? (Select all that apply.)
   a. Stress-reduction techniques
   b. Starting an exercise program
   c. Salt restriction
   d. Smoking cessation
   e. Diet with increased protein
2. A patient has developed mild hypertension. The nurse acknowledges that the first-line drug for treating this patient's blood pressure might be which drug?
   a. Diuretic
   b. Alpha blocker
   c. ACE inhibitor
   d. Alpha/beta blocker
3. An African-American patient has developed hypertension. The nurse is aware that which group(s) of antihypertensive drugs are *less effective* in African-American patients?
   a. Diuretics
   b. Calcium channel blockers and vasodilators
   c. Beta blockers and ACE inhibitors
   d. Alpha blockers
4. The nurse knows that which diuretic is most frequently combined with an antihypertensive drug?
   a. chlorthalidone
   b. hydrochlorothiazide
   c. bendroflumethiazide
   d. potassium-sparing diuretic
5. The nurse is administering a beta blocker to a patient. Which is an important assessment to perform before administration?
   a. Urine output
   b. Apical pulse
   c. Potassium level
   d. Serum level of medication
6. Captopril (Capoten) has been ordered for a patient. The nurse teaches the patient that angiotensin-converting enzyme (ACE) inhibitors have which common side effects?
   a. Nausea and vomiting
   b. Dizziness and headaches
   c. Upset stomach
   d. Constant, irritating cough
7. A patient is prescribed losartan (Cozaar). The nurse teaches the patient that an angiotensin II receptor blocker (ARB) acts by doing what?
   a. Inhibiting angiotensin-converting enzyme
   b. Blocking angiotensin II from AT_1 receptors
   c. Preventing the release of angiotensin I
   d. Promoting the release of aldosterone
8. During an admission assessment, a patient states that she takes amlodipine (Norvasc). The nurse wishes to determine whether the patient has any common side effects of a calcium channel blocker. The nurse asks the patient if she has which signs and symptoms? (Select all that apply.)
   a. Insomnia
   b. Dizziness
   c. Headache
   d. Angioedema
   e. Ankle edema
   f. Hacking cough

Answers: 1, a, b, c, d; 2, a; 3, c; 4, b; 5, b; 6, d; 7, b; 8, b, c, e.

OBJECTIVES

- Compare the action for anticoagulants, antiplatelets, and thrombolytics.
- Differentiate the side effects and adverse reactions of anticoagulants, antiplatelets, and thrombolytics.
- Apply the nursing process, including patient teaching, for anticoagulants and thrombolytics.

OUTLINE

Pathophysiology: Thrombus Formation
Anticoagulants
  Heparin
  Direct Thrombin Inhibitors: Parenteral Anticoagulants II

Various drugs are used to maintain or restore circulation. The three major groups of these drugs are (1) anticoagulants, (2) antiplatelets (antithrombotics), and (3) thrombolytics. The *anticoagulants* prevent the formation of clots that inhibit circulation. The *antiplatelets* prevent platelet **aggregation** (clumping together of platelets to form a clot). The *thrombolytics,* popularly called *clot busters,* attack and dissolve blood clots that have already formed. Each of these three drug groups are discussed separately.

PATHOPHYSIOLOGY: THROMBUS FORMATION

Thrombosis is the formation of a clot in an arterial or venous vessel. The formation of an arterial thrombus could be caused by blood stasis (decreased circulation), platelet aggregation on the blood vessel wall, or blood coagulation. Arterial clots are usually made up of both white and red clots with the white clots *(platelets)* initiating the process, followed by fibrin formation and the trapping of red blood cells in the fibrin mesh. Blood clots found in the veins are from platelet aggregation with fibrin that attaches to red blood cells. Both types of thrombus can be dislodged from the vessel and become an embolus (blood clot moving through the bloodstream).

Platelets do not usually stick together unless there is a break in the endothelial lining of a blood vessel. When platelets adhere to the broken surface of an endothelial lining, they synthesize thromboxane A_2, which is a product of prostaglandins and a potent stimulus for platelet aggregation (clumping of platelet cells). The platelet receptor protein that binds fibrinogen, known as *glycoprotein IIb/IIIa,* or GP IIb/IIIa, also promotes platelet aggregation. Thromboxane A_2 and adenosine diphosphate (ADP) increase the activation of this receptor.

As the thrombus inhibits blood flow, fibrin, platelets, and red blood cells (erythrocytes) surround the clot, building the clot's size and structure. As the clot occludes the blood vessel, tissue ischemia occurs.

The venous thrombus usually develops because of slow blood flow. The venous clot can occur rapidly. Small pieces of the venous clot can detach and travel to the pulmonary artery and then to the lung. Inadequate oxygenation and gas exchange in the lungs result.

Oral and parenteral anticoagulants (warfarin and heparin) act primarily to prevent venous thrombosis, whereas antiplatelet drugs act to prevent arterial thrombosis. However, both groups of drugs suppress thrombosis in general.

ANTICOAGULANTS

Anticoagulants are used to inhibit clot formation. Unlike thrombolytics, they do *not* dissolve clots that have already formed, but rather act prophylactically to prevent new clots from forming. Anticoagulants are used in patients with venous and arterial disorders that put them at high risk for clot formation. Venous problems include deep vein thrombosis (DVT) and pulmonary embolism, and arterial problems include coronary thrombosis, or **myocardial infarction;** presence of artificial heart valves; and cerebrovascular accidents (CVAs, or stroke).

Heparin

Anticoagulants are administered orally or parenterally (subcutaneously [subQ] and intravenously [IV]). Heparin, introduced in 1938, is a natural substance in the liver that prevents clot formation. It was first used in blood transfusions to prevent clotting. Heparin is indicated for rapid anticoagulant effect when a thrombosis occurs because of a deep vein thrombosis (DVT), pulmonary embolism (PE), or an evolving stroke. Heparin is also used in open-heart surgery to prevent blood from clotting and in the critically ill patient with disseminated intravascular coagulation (DIC). DIC occurs when fibrin clots form within the vascular system. These clots consume proteins and platelets, depleting clotting factors and causing excess bleeding. However, the primary use of heparin is to prevent venous thrombosis, which can lead to pulmonary embolism or stroke.

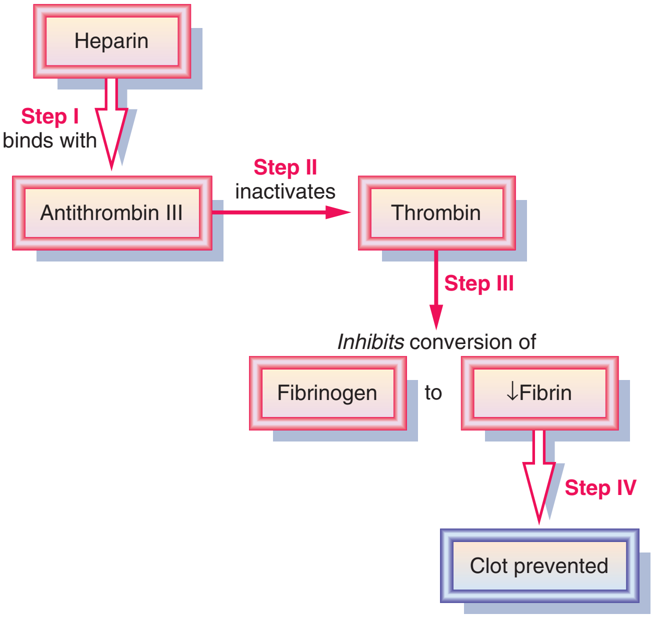

FIGURE 45–1 Action of the parenteral anticoagulant heparin.

Heparin combines with antithrombin III, which accelerates the anticoagulant cascade of reactions that prevents thrombosis formation. By inhibiting the action of thrombin, conversion of fibrinogen to fibrin does not occur and the formation of a fibrin clot is prevented (Figure 45-1).

Heparin is poorly absorbed through the gastrointestinal (GI) mucosa, and much is destroyed by heparinase, a liver enzyme. Because heparin is poorly absorbed orally, it is given subQ for prophylaxis or IV to treat acute thrombosis. It can be administered as an IV bolus or in IV fluid for continuous infusion. Heparin prolongs clotting time. **Partial thromboplastin time** (PTT) and **activated partial thromboplastin time** (aPTT) are laboratory tests used to detect deficiencies of certain clotting factors, and these tests are used to monitor heparin therapy. Heparin can decrease the platelet count, causing thrombocytopenia. If hemorrhage occurs during heparin therapy, the anticoagulant antagonist protamine sulfate is given IV. Protamine sulfate can be an anticoagulant, but in the presence of heparin, it is an antagonist to reverse the action of heparin. Before discontinuing heparin, oral therapy with warfarin therapy is begun.

Low–Molecular-Weight Heparins

These derivatives of standard heparin were introduced to prevent venous thromboembolism. Studies have shown that by extracting only the low–molecular-weight fractions of standard heparin through depolymerization, the equivalent of anticoagulation can be achieved with a lower risk of bleeding. Low–molecular-weight heparins (LMWHs) produce more stable responses at recommended doses. As a result, frequent laboratory monitoring of aPTT is not required, because LMWH does not have the standard effect of heparin. Heparin prevents coagulation by combining with

Antithrombin III to inactivate factor Xa and thrombin. Low–molecular-weight heparin inactivates the Xa factor, but it is less able to inactivate thrombin.

There are examples of LMWHs include enoxaparin sodium (Lovenox) and dalteparin sodium (Fragmin).

SAFETY: Preventing Medication Errors

Do not confuse…

- **Enoxaparin** (LMWH) and **enoxacin** (fluoroquinolone antibiotic)
- **Lovenox** (LMWH) and **Lotronex** (gastrointestinal drug)

The anticoagulant fondaparinux (Arixtra) is a synthetically engineered antithrombotic designed to be effective as a once-daily subcutaneous injection. Categorized as a *selective Factor Xa inhibitor,* fondaparinux is closely related in structure to heparin and LMW heparins and is used for the same purposes.

These agents are most commonly prescribed to prevent DVT and acute pulmonary embolism after orthopedic or abdominal surgery. Hip- and knee-replacement anticoagulant therapy often includes enoxaparin, and abdominal surgery includes dalteparin. The drugs can be administered at home, because aPTT monitoring is not necessary, whereas heparin must be given in the hospital. LMWHs are administered subQ once or twice a day, depending on the drug or drug regimen, and are available in prefilled syringes with attached needles. The patient or family member is taught how to administer the subQ injection, which is usually given in the abdomen. The average treatment period lasts 7 to 10 days. The LMWH is usually started in the hospital within 24 hours after surgery (Table 45-1).

The half-life of LMWHs is two to four times longer than that of heparin. Patients should be instructed not to take antiplatelet drugs such as aspirin while taking LMWHs or heparin. Bleeding because of LMWH use is less likely to occur than when heparin is given. LMWH overdose is rare; if bleeding occurs, protamine sulfate is the anticoagulant antagonist used. The dosage is 1 mg of protamine sulfate for every 100 units of unfractionated heparin or LMWH given.

Contraindications

The LMWHs are contraindicated for patients with strokes, peptic ulcers, and blood anomalies. These drugs should not be given to patients having eye, brain, or spinal surgery.

Direct Thrombin Inhibitors: Parenteral Anticoagulants II

Parenteral anticoagulants directly inhibit thrombin from converting fibrinogen to fibrin. These drugs differ from heparin-like anticoagulants. Three of these drugs are given intravenously: argatroban (Acova), bivalirudin (Angiomax), and lepirudin (Refludan). Bivalirudin binds with and inhibits free-flowing thrombin. The fourth drug, desirudin (Iprivask),

TABLE 45-1 ANTICOAGULANTS AND ANTICOAGULANT ANTAGONISTS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Anticoagulants		
Heparins		
heparin sodium	See Prototype Drug Chart 45-1.	
Low–Molecular-Weight Heparins (LMWHs)		
dalteparin sodium (Fragmin)	Surgery: A: subQ: 2500 international units/d for 5-10 d starting 1-2 h before surgery DVT: A: subQ: 5000 units/d or q12h for 2-6 mo	For prevention of DVT before surgery and for those at risk of thromboembolism. Similar to enoxaparin. Pregnancy category: B; PB: <10%; t½: 3-5 h
enoxaparin sodium (Lovenox)	A: subQ: 40 mg daily for 5 to 10 d	For thromboembolism. Prevents and treats DVT and pulmonary embolism. Bleeding is an adverse reaction. Monitor CBC. Pregnancy category: B; PB: UK; t½: 4.5 h
Oral Anticoagulants		
Coumarin		
warfarin (Coumadin)	See Prototype Drug Chart 45-1.	
Selective Factor Xa Inhibitors		
fondaparinux (Arixtra)	A: subQ: 2.5-10 mg/d for 5-9 d	Indirectly inhibits factor Xa, preventing blood clots. Closely related to heparin and LMWHs. Used to prevent DVT after hip fracture, hip replacement surgery, and knee replacement surgery and treat pulmonary emboli. May cause more bleeding than LMWHs. Long duration of action. Pregnancy category: B; PB: 94%; t½: 17-21 h

TABLE 45-1 ANTICOAGULANTS AND ANTICOAGULANT ANTAGONISTS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
rivaroxaban (Xarelto)	A: PO: 10-20 mg once daily with evening meal; *max:* 30 mg/d	For prophylaxis of DVT and PE in patients undergoing knee or hip replacement surgery, stroke, and atrial fibrillation. Not easily reversed. Does not require routine coagulation monitoring. Pregnancy category: C; PB: 92%-95%; t½: 5-9 h
apixaban (Eliquis)	A: PO: 5 mg b.i.d.	To prevent stroke and thromboembolism associated with nonvalvular atrial fibrillation. Routine coagulation monitoring not required. Pregnancy category: B; PB: 87%; t½: 5-12 h
Direct-Acting Thrombin Inhibitors: Anticoagulants II (Intravenous)		
argatroban (Argatroban)	A: IV: 2 mcg/kg/min; adjust dose to maintain aPTT 1.5-3 times baseline; *max:* 10 mcg/kg/min	Directly inhibits thrombin (thrombin inhibitor). Same effect as lepirudin. Decreases development of new thrombosis and treats heparin-induced thrombocytopenia (HIT). Pregnancy category: C; PB: 54%; t½: 40-52 min
bivalirudin (Angiomax)	A: IV bolus: 0.75 mg/kg; then IV infusion of 1.75 mg/kg/h during and within 4 h postprocedure; may require 0.2 mg/kg/h up to 20 h	Inhibits thrombin by binding to its receptor sites. Has been effective for use in preventing clot formation in patients with unstable angina who are undergoing cardiac angioplasty. Adverse effect is bleeding. Pregnancy category: B; PB: 0%; t½: 25 min
desirudin (Iprivask)	A: subQ: 15 mg/12 h for 9-12 d	Interferes with fibrin production, platelet aggregation, and factor XII activation, and inactivates thrombin. Given for DVT prophylaxis. Pregnancy category: C; PB: UK, t½: 2-3 h
lepirudin (Refludan)	A: IV bolus: 0.2-0.4 mg/kg over 15-20 sec; follow with 0.15 mg/kg/h for 2-10 d	Directly inhibits thrombin. Used for prophylaxis and treatment of thrombosis due to HIT. Titrated to aPTT ratio. Liver function should be normal. Adverse effect is bleeding. Pregnancy category: B; PB: UK; t½: 1.3 h
dabigatran (Pradaxa)	A: PO: 150 mg b.i.d.; *max:* 300 mg/d	For prevention of stroke and atrial fibrillation. Assess renal function before initiating drug and periodically throughout therapy. Pregnancy category: C; PB: 35%; t½: 12-17 h
Anticoagulant Antagonists		
protamine sulfate	A: IV: Initially: 1 mg/100 units heparin; administer 10-50 mg in 10-15 min IV push; *max:* 100 mg in 2-h period	Binds and neutralizes heparin. Antidote to heparin overdose. Pregnancy category: C; PB: UK; t½: 7.4 min
phytonadione, Vitamin K_1 (Mephyton)	A: PO/IM/IV: 1-10 mg, q12-24h PRN C: subQ/IM: 0.5-5 mg	Promotes liver synthesis of clotting factors. Antidote for warfarin overdose. Pregnancy category: C; PB: UK; t½: UK

A, Adult; *aPTT,* activated partial thromboplastin time; *b.i.d.,* twice a day; *C,* child; *CBC,* complete blood count; *d,* day; *DVT,* deep vein thrombosis; *h,* hour; *HIT,* heparin-induced thrombocytopenia; *IM,* intramuscular; *IV,* intravenous; *inf,* infusion; *INR,* international normalized ratio; *LD,* loading dose; *LMWH,* low–molecular-weight heparin; *maint,* maintenance; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *PT,* prothrombin time; *sec,* second; *subQ,* subcutaneous; *t½,* half-life; *UK,* unknown.

is administered subcutaneously. Dabigatran (Pradaxa) is an oral anticoagulant that does not require routine coagulation monitoring (see Table 45-1). These drugs are more expensive than the other anticoagulants.

Oral Anticoagulants

Warfarin (Coumadin) is an oral anticoagulant from the coumarin drug family. Dicumarol, a coumarin drug, and anisindione from the indanedione group, have been discontinued because of their many side effects. Warfarin is synthesized from dicumarol. Before warfarin was available for human use, it was used in rodenticides to kill rats by causing hemorrhage.

Oral anticoagulants inhibit hepatic synthesis of vitamin K, thus affecting the clotting factors II, VII, IX, and X. Warfarin is used mainly to prevent thromboembolic conditions such as thrombophlebitis, pulmonary embolism, and embolism formation caused by atrial fibrillation, which can lead to stroke (CVA). Oral anticoagulants prolong clotting time and are monitored by the **prothrombin time** (PT), a laboratory test that measures the time it takes blood to clot in the presence of certain clotting factors, which warfarin affects. This laboratory test is usually performed immediately before administering the next drug dose until the therapeutic level has been reached. Today, **international normalized ratio** (INR) is the laboratory test most frequently used to report PT results. It was introduced to account for variability in reported PTs from different laboratories. Reagents used in the PT test are compared with an international reference standard and reported as the INR; normal INR is 1.3 to 2. Patients on warfarin therapy are maintained at an INR of 2 to 3. The desired INR for patients who have a mechanical heart valve or recurrent systemic embolism is 2.5 to 3.5, but the desired level could be as high as 4.5.

Monitoring INR at regular intervals is required for the duration of drug therapy. Warfarin (Coumadin) has a long half-life and very long duration. Drug accumulation can occur and lead to external or internal bleeding, so the nurse must observe for petechiae, ecchymosis, tarry stools, and hematemesis and teach the patient to do the same at home.

The antidote for warfarin overdose is Vitamin K, but it takes 24 to 48 hours to be effective. Usually a low dose of oral Vitamin K may be recommended for patients with an INR of 5.5. If excessive Vitamin K is given, it may take warfarin 1 to 2 weeks before it can be effective again. For acute bleeding, fresh frozen plasma is indicated.

Parenteral and oral anticoagulants (heparin and warfarin) are presented in Prototype Drug Chart 45-1.

Pharmacokinetics Heparin is poorly absorbed through the GI mucosa, and much is destroyed by heparinase, a liver enzyme. Heparin is given parenterally, either subcutaneously for prophylactic anticoagulant therapy or IV (bolus or continuous infusion) for an immediate response. Warfarin, an oral anticoagulant, is well absorbed through the GI mucosa; food will delay but not inhibit absorption.

PROTOTYPE DRUG CHART 45-1

Heparin and Warfarin Sodium

Drug Class

Anticoagulant
Trade Name (warfarin): Coumadin
Pregnancy Category: C (heparin)
Pregnancy Category: X (warfarin)

Dosage

Heparin:
A: subQ: 5000-10,000 units q4-12h
IV: Bolus: 5000 units; inf: 20,000-40,000 units over 24 h based on APTT
C: IV: 50 units/kg bolus; then 5-100 units/kg q4h based on APTT
Warfarin:
A: PO: LD: 5-10 mg/d for 2-5 d; *maint:* 2-10 mg/d
C: PO: 0.05-0.2 mg/kg/d; titrate to INR

Contraindications

Heparin/warfarin: Bleeding disorder, peptic ulcer, severe hepatic or renal disease, hemophilia
Warfarin: Blood dyscrasias, eclampsia, alcoholism, bleeding, head trauma
Caution: diabetes mellitus, leukemia

Drug-Lab-Food Interactions

Drug: heparin: Increase effect with aspirin, NSAIDs, thrombolytics, probenecid; decrease effect with nitroglycerin, protamine sulfate
Warfarin: Increase effect with amiodarone, aspirin, NSAIDs, sulfonamides, thyroid drugs, allopurinol, histamine$_2$ blockers, oral hypoglycemics, metronidazole, miconazole, methyldopa, diuretics, oral antibiotics, vitamin E; decrease effect with barbiturates, laxatives, phenytoin, estrogens, vitamins C and K, oral contraceptives, rifampin
Lab: May increase AST, ALT
Food: Decrease diet rich in vitamin K

Pharmacokinetics

Absorption: heparin: subQ or IV; warfarin: PO: Well absorbed
Distribution: PB: heparin: >80%; warfarin: 99%
Metabolism: t½: heparin: 0.5-2.5 h; warfarin: 1-7 d
Excretion: heparin: Slowly in urine and reticuloendothelial system; warfarin: in urine and bile

Pharmacodynamics

Heparin:
subQ: Onset: 20-60 min
Peak: 2 h
Duration: 8-12 h
IV: Onset: immediate
Peak: 5-10 min
Duration: 2-6 h
Warfarin:
PO: Onset: >2 d
Peak: 1-3 d
Duration: 2.5-5 d

Therapeutic Effects/Uses

Heparin/warfarin: To prevent blood clotting
Mode of Action: heparin: Inhibits thrombin, which prevents conversion of fibrinogen to fibrin
Warfarin: Depresses hepatic synthesis of vitamin K clotting factors (II [prothrombin], VII, IX, and X)

Side Effects

Heparin: Itching, burning, chills, injection site reaction
Warfarin: Anorexia, nausea, vomiting, diarrhea, abdominal cramps, rash, alopecia, fever, stomatitis

Adverse Reactions

Heparin: Bleeding, ecchymoses, hematuria, angioedema, osteoporosis, stroke, heparin-induced thrombocytopenia
Life-threatening: Hemorrhage
Warfarin: Purple-toe syndrome
Life-threatening: Hemorrhage

A, Adult; *ALT,* alanine aminotransferase; *aPTT,* activated partial thromboplastin time; *AST,* aspartate aminotransferase; *C,* child; *CVA,* cerebrovascular accident; *d,* day; *h,* hour; *inf,* infusion; *INR,* international normalized ratio; *IV,* intravenous; *LD,* loading dose; *maint,* maintenance; *min,* minute; *NSAIDs,* nonsteroidal antiinflammatory drugs; *PB,* protein-binding; *PO,* by mouth; *subQ,* subcutaneous; *t ½,* half-life, *>,* greater than.

The half-life of heparin is dose-related; high doses prolong the half-life. The half-life of warfarin is 1 to 7 days, in contrast to 0.5 to 2.5 hours for heparin. Because warfarin has a long half-life and is highly protein-bound, the drug can have cumulative effects. Bleeding can occur, especially if another highly protein-bound drug is administered together with warfarin. Kidney and liver disease prolong the half-life of both heparin and warfarin. Warfarin is metabolized to inactive metabolites that are excreted in urine and bile.

Pharmacodynamics Heparin, administered for acute thromboembolic disorders, prevents thrombus formation and embolism. It has been effectively used to treat DIC, which causes multiple thrombi in small blood vessels. Warfarin is effective for long-term anticoagulant therapy. The PT level should be 1.5 to 2 times the reference value to be therapeutic, or INR should be 2.0 to 3.0. INR has effectively replaced the use of PT, because PT can vary from laboratory to laboratory and reagent to reagent. Higher INR levels (up to 3.5) are usually required for patients with prosthetic heart valves, cardiac valvular disease, and recurrent emboli. Heparin does not cross the placental barrier, unlike warfarin; warfarin use is not recommended during pregnancy.

Intravenous heparin has a rapid onset; its peak time of action is reached in minutes, and its duration of action is short. After an IV heparin dose, the patient's clotting time will return to normal in 2 to 6 hours. SubQ heparin is more slowly absorbed through the blood vessels in fatty tissue. Warfarin (Coumadin) has a long onset of action, peak concentration, and duration of action, so drug accumulation may occur.

Table 45-2 gives the summary comparison between heparin and warfarin, including methods of administration, drug action, uses, contraindications, laboratory tests, side effects, adverse reactions, and antidotes.

Side Effects and Adverse Reactions. Bleeding (hemorrhage) is the major adverse effect of warfarin. Patients should be monitored closely for signs of bleeding (e.g., petechiae, ecchymosis, hematemesis). Laboratory testing of PT or INR should be scheduled at recommended intervals.

Drug Interactions. Because warfarin is highly protein-bound, it is affected by drug interactions. Aspirin, nonsteroidal antiinflammatory drugs (NSAIDs), other types of antiinflammatory drugs, sulfonamides, phenytoin (Dilantin), cimetidine (Tagamet), allopurinol (Zyloprim), and oral hypoglycemic drugs for diabetes can displace warfarin from the protein-bound site, causing more free-circulating anticoagulant. Numerous other drugs also increase the action of warfarin, and bleeding is likely to occur. Acetaminophen (Tylenol) should be used instead of aspirin by patients taking warfarin. For frank bleeding resulting from excess free drug, parenteral vitamin K is given as a coagulant to decrease bleeding and promote clotting. However, caution must be used with this approach, because the prothrombin can remain depressed for prolonged periods.

Table 45-1 lists the pharmacologic data for the anticoagulants.

Xa Inhibitor: Oral Anticoagulants. Two new oral anticoagulants form a new anticoagulant category called Xa inhibitors. Rivaroxaban (Xarelto) was FDA approved in July 2011, and apixaban (Eliquis) was FDA approved in December 2012. These drugs do not require routine coagulation monitoring and are given once or twice daily (see Table 45-1).

Anticoagulant Antagonists

Bleeding occurs in about 10% of patients taking oral anticoagulants. Vitamin K_1 (phytonadione), an antagonist of warfarin, is used for warfarin overdose or uncontrollable bleeding. Usually 1 to 10 mg of vitamin K_1 is given at once, and if it fails to control bleeding, then fresh whole blood or fresh-frozen plasma or platelets are generally given.

TABLE 45-2 COMPARISON OF PARENTERAL AND ORAL ANTICOAGULANTS

FACTORS TO CONSIDER	HEPARIN	WARFARIN (COUMADIN)
Methods of administration	Subcutaneously Intravenously	Primarily orally
Drug actions	Binds with antithrombin III, which inactivates thrombin and clotting factors, inhibiting fibrin formation	Inhibits hepatic synthesis of vitamin K, which decreases prothrombin and the clotting factors VII, IX, and X
Uses	Treatment of venous thrombosis, pulmonary embolism, thromboembolic complications (e.g., heart surgery, disseminated intravascular coagulation)	Treatment of deep vein thrombosis, pulmonary embolism, transient ischemic attack; prophylactic for cardiac valves
Contraindications/cautions	Hemophilia, peptic ulcer, severe (stage 3 or 4) hypertension, severe liver or renal disease, dissecting aneurysm	Hemophilia, peptic bleeding ulcer, blood dyscrasias, severe liver or kidney disease, acute myocardial infarction, alcoholism
Laboratory tests	PTT: 60-70 sec Anticoagulant therapeutic level: 1.5 to 2 × control in seconds aPTT: 20-35 sec Anticoagulant: aPTT: 30-85 sec	PT: 11-15 sec Anticoagulant therapeutic level: 1.25 to 2.5 × control in seconds INR: 1.3-2 Anticoagulant: INR 2-3 Prosthetic heart valves: INR up to 3.5
Side/adverse effects	Bleeding, hemorrhage, hematoma, severe hypotension	Bleeding, hemorrhage, GI bleeding, ecchymoses, hematuria
Antidote	Protamine sulfate: 1 mg per 100 units of heparin (see Table 45-1)	Vitamin K_1 PO/subQ/IM/IV: 2.5-10 mg, C: subQ/IM: 5-10 mg Infant: 1 mg

A, Adult; *aPTT,* activated partial thromboplastin time; *C,* child; *d,* day; *GI,* gastrointestinal; *IM,* intramuscular; *INR,* international normalized ratio; *IV,* intravenous; *PO,* by mouth; *PT,* prothrombin time; *PTT,* partial thromboplastin time; *sec,* second; *subQ,* subcutaneous.

Nursing Process

Patient-Centered Collaborative Care

Anticoagulants: Warfarin and Heparin

Assessment

- Obtain a history of abnormal clotting or health problems that affect clotting, such as severe alcoholism or severe liver or renal disease. Warfarin is contraindicated for patients with blood dyscrasias, peptic ulcer, cerebrovascular accident (CVA), hemophilia, or severe hypertension. Use with caution in patients with acute traumatic injury.
- Gather a drug and herbal history of current drugs and herbs patient takes. Report if drug-drug or drug-herbal interaction is probable. Warfarin is highly protein-bound and can displace other highly protein-bound drugs, or warfarin could be displaced, which may result in bleeding.
- Develop a flowchart that lists prothrombin time (PT) or international normalized ratio (INR) and warfarin dosages. A baseline PT or INR should be obtained before warfarin is administered.

Nursing Diagnoses

- Risk for injury related to bleeding due to adverse effect of heparin or warfarin
- Deficient knowledge related to lack of previous exposure to side effects of anticoagulants and their action

Planning

- Patient's PT will be 1.25 to 2.5 times control level, or INR will be 2 to 3.
- Patient will not have excessive bleeding.
- Patient's aPTT level will be within a therapeutic range.

Nursing Interventions

- Monitor vital signs. An increased pulse rate followed by a decreased systolic pressure can indicate a fluid volume deficit resulting from external or internal bleeding.
- Monitor PT or INR for warfarin (Coumadin) and aPTT for heparin before administering anticoagulant. PT should be 1.25 to 2.5 times control level or INR 2 to 3, except for prosthetic heart valves (up to INR 3.5). Monitor platelet count (anticoagulants can decrease platelet count).
- Examine patient's mouth, nose (epistaxis), urine (hematuria), and skin (petechiae, purpura) for bleeding. Watch older adults closely for bleeding; their skin is thin, and capillary beds are fragile.
- Check stools periodically for occult blood.
- Keep anticoagulant antagonists (protamine sulfate for heparin and vitamin K for warfarin) available when drug dose is increased or there are indications of frank bleeding. Fresh-frozen plasma may be needed for transfusion.

Patient Teaching

General

- Teach patient to inform dentist when taking an anticoagulant. Contacting health care provider may be necessary.
- Advise patient to use a soft toothbrush to prevent gums from bleeding.
- Warn patient to shave with an electric razor. Bleeding from shaving cuts may be difficult to control.
- Advise patient to have laboratory tests such as PT or INR performed as ordered by health care provider. Warfarin dose is regulated according to INR derived from PT.
- Suggest that patient carry medical identification card or wear MedicAlert bracelet that lists name, telephone number, and drug taken.
- Encourage patient *not* to smoke. Smoking increases drug metabolism, so warfarin dose may need to be increased. If patient insists on smoking, notify health care provider.
- Tell patient to check with health care provider before taking OTC drugs. Aspirin should *not* be taken with warfarin, because aspirin intensifies its action and bleeding is apt to occur. Suggest that patient use acetaminophen.
- Inform patient that many herbal products interact with anticoagulants and may increase bleeding (Herbal Alert 45-1). Closely monitor international normalized ratio (INR) or prothrombin time (PT).
- Teach patient to control external hemorrhage (bleeding) from accidents or injuries by applying firm, direct pressure for at least 5 to 10 minutes with a clean, dry, absorbent material.

Side Effects

- Warn patient to report frank or occult bleeding (petechiae, ecchymosis, purpura, tarry stools, bleeding gums, epistaxis, expectoration of blood).

Diet

- Advise patient to avoid large amounts of green, leafy vegetables; broccoli; legumes; soybean oil (rich in vitamin K); coffee, tea, cola (caffeine); excessive alcohol; and certain herbs and nutritional supplements (coenzyme Q10) or to be very consistent with their intake. Coenzyme Q10, fish oils, items high in vitamin K, St. John's wort, ginseng, and vitamin C may decrease effectiveness of warfarin. Garlic, ginger, kava kava, green tea, chamomile tea, ginkgo biloba, and acute alcohol intoxication decrease warfarin effectiveness.

Cultural Considerations

- Provide instructions in language patient speaks and reads most easily. Certain cultural groups may lack understanding of Western approaches to health problems, drug therapy, adverse effects, and follow-up care concerning thrombophlebitis or other conditions that cause thrombus formation.
- Identify conflicts in cultural values and beliefs of patient regarding method for treating a vascular problem. Respect traditional practices, and incorporate them into care plan if harmless. If method may be harmful, initiate explanations along with nursing plan.

Evaluation

- Evaluate effectiveness of drug therapy. Patient's PT or INR values are within desired range, and patient is free from significant side effects.

HERBAL ALERT 45-1

Anticoagulants: Warfarin and Heparin

- Dong quai, feverfew, garlic, ginger, green tea, chamomile tea, ginkgo, and bilberry may increase bleeding when taken with anticoagulants such as warfarin. Warfarin has an additive effect and increases the international normalized ratio and prothrombin time.
- Excessive doses of anise may interfere with anticoagulants.
- Ginseng may decrease the effects of warfarin, thereby decreasing INR.
- Alfalfa may decrease anticoagulant activity.
- Goldenseal may decrease the effects of heparin and oral anticoagulants.
- Black haw increases the action of anticoagulants.
- Valerian may decrease the effects of warfarin.

ANTIPLATELET DRUGS

Antiplatelets are used to prevent thrombosis in the arteries by suppressing platelet aggregation. Heparin and warfarin prevent thrombosis in the veins.

Antiplatelet drug therapy is mainly for prophylactic use in (1) prevention of myocardial infarction or stroke for patients with familial history, (2) prevention of repeat myocardial infarction or stroke, and (3) prevention of stroke for patients having transient ischemic attacks (TIAs).

Long-term, low-dose aspirin therapy has been found to be both an effective and inexpensive treatment for suppressing platelet aggregation. Aspirin inhibits cyclooxygenase, an enzyme needed by platelets to synthesize thromboxane A_2 (TxA_2). For patients with familial history of stroke or myocardial infarction, the recommended aspirin dose is 81, 162, or 325 mg/d. Because aspirin has prolonged antiplatelet activity, it should be discontinued at least 7 days before surgery.

Other antiplatelet drugs include dipyridamole (Persantine), ticlopidine (Ticlid), clopidogrel (Plavix), anagrelide HCl (Agrylin), abciximab (ReoPro), eptifibatide (Integrilin), tirofiban (Aggrastat), and ticagrelor (Brilinta). Clopidogrel, dipyridamole, and ticlopidine have similar effects as aspirin, but they are known as *adenosine diphosphate (ADP) antagonists* affecting platelet aggregation. Cilostazol (Pletal) inhibits platelet aggregation and is a vasodilator that may be used for intermittent claudication. Ticagrelor is taken in conjunction with aspirin 75 to 100 mg in a maintenance regime. Doses greater than 100 mg should be avoided. Table 45-3 lists the antiplatelets and their dosages, uses, and considerations.

Clopidogrel (Plavix) is an antiplatelet drug frequently used after myocardial infarction or stroke to prevent a second event. It may be prescribed singly or with aspirin. It has been stated that Plavix and aspirin are more effective in inhibiting platelet aggregation if used together than if used as separate antiplatelet therapies. Prototype Drug Chart 45-2 lists the pharmacologic data for clopidogrel (Plavix).

Pharmacokinetics Clopidogrel (Plavix) is rapidly absorbed and has a high protein-binding power. Studies have not established a relationship between the concentration of the main metabolite and platelet aggregation. The half-life is 8 hours; it is usually prescribed once a day. Excretion of the drug metabolite occurs equally in the urine and feces.

Pharmacodynamics Clopidogrel (Plavix) prevents platelet aggregation by blocking the binding of adenosine diphosphate (ADP) to the platelet ADP receptor. ADP-mediated activation of the glycoprotein (GP) IIb/IIIa complex inhibits platelet aggregation. Plavix prolongs bleeding time; therefore it should be discontinued for 7 days preceding surgery. The onset of action of Plavix is 1 to 2 hours, and its peak time is 2 to 3 hours. The drug should not be taken if the patient has a bleeding peptic ulcer, any active bleeding, or intracranial hemorrhage.

Abciximab, eptifibatide, and tirofiban are used primarily for acute coronary syndromes (unstable angina or non–Q-wave myocardial infarction) and for preventing reocclusion of coronary arteries following percutaneous transluminal coronary angioplasty (PTCA). These drugs are usually given before and after PTCA. The drug of choice for angioplasty is abciximab. Abciximab, eptifibatide, and tirofiban block the binding of fibrinogen to the glycoprotein IIb/IIIa receptor on the platelet surface. They are called *platelet glycoprotein (GP) IIb/IIIa receptor antagonists.* Following IV infusion, the antiplatelet effects for abciximab persist for 24 to 48 hours; for eptifibatide and tirofiban, the antiplatelet effects last for 4 hours.

Herbal products can interact with antiplatelet drugs (Herbal Alert 45-2).

THROMBOLYTICS

Thromboembolism (occlusion of an artery or vein caused by a thrombus or embolus) results in **ischemia** (deficient blood flow) that causes **necrosis** (death) of the tissue distal to the obstructed area. It takes approximately 1 to 2 weeks for the blood clot to disintegrate by natural fibrinolytic mechanisms. If a new thrombus or embolus can be dissolved more quickly, tissue necrosis is minimized, and blood flow to the area is reestablished faster. This is the basis for thrombolytic therapy.

Thrombolytics have been used since the early 1980s to promote the fibrinolytic mechanism (converting plasminogen to plasmin, which destroys the fibrin in the blood clot). The thrombus, or blood clot, disintegrates when a thrombolytic drug is administered within 4 hours after an **acute**

TABLE 45-3 ANTIPLATELETS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
anagrelide HCl (Agrylin)	A: PO: 1 mg, b.i.d. May increase by 0.5 mg/d every wk if necessary until platelet count: <600,000 mcL; *max:* 10 mg/d	Selectively inhibits platelet production. Inhibits platelet aggregation; affects aggregating agents ADP, cAMP PDE III, and collagen. Adverse reactions include HF, heart block, pulmonary hypertension, and cardiomyopathy. Pregnancy category: C; PB: UK; t½: 3-4 d
aspirin, ASA (Bayer, Stanback, Aspergum)	A: PO: 75-100 mg/d	For prevention of thrombosis before or after CVA or MI. Patient should check with health care provider before taking aspirin for antiplatelet therapy. Aspirin not recommended for patients with peptic ulcer or liver dysfunction. Enteric-coated preparation decreases GI upset. Pregnancy category: D; PB: 76%-90%; t½: 15-20 min
cilostazol (Pletal)	A: PO: 100 mg, b.i.d. 30 min before or 2 h after meals	Inhibits platelet aggregation and is a vasodilator. Indicated for intermittent claudication, peripheral vascular disease. Smoking may decrease serum levels. Adverse reactions include HF, tachycardia, cerebral ischemia, and atrial flutter or fibrillation. Pregnancy category: C; PB: 95%-98%, t½: 11-13 h
clopidogrel (Plavix)	See Prototype Drug Chart 45-2.	
dipyridamole (Persantine)	A: PO: 75-100 mg q.i.d.	For prevention of thromboembolism post-MI and associated with prosthetic devices (heart valves and hip replacement); prevention of TIA. Monitor blood pressure. Pregnancy category: B; PB: 91%-99%; t½: 10-12 h
prasugrel (Effient)	A: PO: Loading dose: 60 mg; maint: 10 mg/d	For prevention of thrombotic cardiovascular event. Patient should also take aspirin 75-325 mg/d with prasugrel. Monitor patient for bleeding. Pregnancy category: B; PB: 98%, t½: 2-15 h
ticlopidine (Ticlid)	A: PO: 250 mg b.i.d.	To reduce risk of strokes and thrombin formation. To treat intermittent claudication and sickle cell disease. Not recommended for patients with hematopoietic disorders such as thrombocytopenia or bleeding peptic ulcer. Pregnancy category: B; PB: 98%: t½: 8-12 h
ticagrelor (Brilinta)	A: PO: Loading dose: 180 mg with aspirin 325 mg; then 90 mg b.i.d. with aspirin 75-100 mg/d; *max:* 180 mg/d ticagrelor and 100 mg/d aspirin	For prevention of thrombotic cardiovascular event in acute coronary syndrome. Does not have irreversible effects on platelets. Given in combination with aspirin. Pregnancy category: C; PB: 99%: t½: 7 h
Combination of Antiplatelet Drugs		
dipyridamole and aspirin (Aggrenox)	Stroke prevention: 1 cap b.i.d. (aspirin 25 mg and ER-dipyridamole 200 mg)	Combination of aspirin and ER-dipyridamole for stroke prevention in patients who have had TIA
Antiplatelets: Glycoprotein (GP) IIb/IIIa Receptor Antagonists		
abciximab (ReoPro)	A: IV bolus: 0.25 mg/kg given 10-60 min before PTCA. Inject 4.5 mL abciximab into 250 mL NSS or D_5W. Follow with continuous infusion of 0.125 mcg/kg/min for next 12 h; *max:* 10 mcg/min	To prevent acute cardiac ischemia before and following PTCA and for unstable angina. May cause intracranial hemorrhage. Pregnancy category: C; PB: UK; t½: 10-30 min
eptifibatide (Integrilin)	A: IV bolus: 180 mcg/kg, then 2 mcg/kg/min for up to 72 h	For acute cardiac syndromes (unstable angina and non–Q-wave MI). Can be used with angioplasty. Pregnancy category: B; PB: 25%; t½: 1.5-2 h
tirofiban (Aggrastat)	A: IV: 0.4 mcg/kg/min for 30 min, then 0.1 mcg/kg/min for 12-24 h after angioplasty	For acute cardiac syndromes (unstable angina and non–Q-wave MI). May be used with angioplasty. Pregnancy category: B; PB: 65%; t½ : 2 h

ADP, Adenosine diphosphate; *AV,* arteriovenous; *cAMP,* cyclic adenosine monophosphate; *cap,* capsule; *HF,* heart failure; *CVA,* cerebrovascular accident; *d,* day; *ER,* extended-release; *GI,* gastrointestinal; *h,* hour; *maint,* maintenance; *max,* maximum; *MI,* myocardial infarction; *NSS,* normal saline solution; *PTCA,* percutaneous transluminal coronary angioplasty; *q.i.d.,* four times a day; *t½,* half-life; *TIA,* transient ischemic attack; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week; *>,* greater than.

PROTOTYPE DRUG CHART 45-2

Clopidogrel Bisulfate

Drug Class Antiplatelet Trade Name: Plavix Pregnancy Category: B	**Dosage** A: PO: loading dose: 300 mg and then 75 mg/d
Contraindications Intracranial hemorrhage, peptic ulcer, GI bleeding, Caution: Liver disease, surgery, bleeding from trauma, renal disease	**Drug-Lab-Food Interactions** Drug: May increase bleeding when taken with NSAIDs, anticoagulants, antineoplastics, azole antifungals, barbiturates; interferes with metabolism of phenytoin, warfarin, fluvastatin, tamoxifen, tolbutamide, NSAIDs, torsemide Lab: Prolongs bleeding time Herb: May increase bleeding when taken with ginger, garlic, ginkgo, feverfew, green tea
Pharmacokinetics Absorption: Rapid Distribution: PB: 94%-98% Metabolism: $t_{1/2}$: 8 h Excretion: 50% in urine and 50% in feces	**Pharmacodynamics** PO: Onset: 1-2 h Peak: 2-3 h Duration: 3 d or longer
Therapeutic Effects/Uses To prevent recurrence of MI, stroke; to prevent vascular death. Mode of Action: Inhibits platelet aggregation. Prevents ADP from binding with the ADP platelet receptor.	
Side Effects Abdominal pain, flulike symptoms, dizziness, epistaxis, headaches, fatigue, chest pain, diarrhea	**Adverse Reactions** Hypotension, bronchospasm Life-threatening: Agranulocytosis, aplastic anemia, thrombocytopenia

A, Adult; *ADP,* adenosine diphosphate; *GI,* gastrointestinal; *h,* hour; *PB,* protein-binding; *PO,* by mouth; *MI,* myocardial infarction; *NSAIDs,* nonsteroidal antiinflammatory drugs; *RTI,* respiratory tract infection; $t_{1/2}$, half-life.

HERBAL ALERT 45-2

Antiplatelets

Dong quai, feverfew, garlic, and *ginkgo biloba* interfere with platelet aggregation. When these herbs are taken with an antiplatelet drug such as aspirin, increased bleeding may occur.

myocardial infarction (AMI) (acute heart attack). Necrosis resulting from the blocked artery is prevented or minimized, and hospitalization time may be decreased. The need for cardiac bypass or coronary angioplasty can be evaluated soon after thrombolytic treatment. A thrombolytic drug should be administered within 3 hours of a thrombolic stroke. These drugs are also used for pulmonary embolism, DVT, noncoronary arterial occlusion from an acute thromboembolism, and thrombolic stroke.

Commonly used thrombolytics include urokinase (Abbokinase), alteplase tPA (Activase), reteplase rPA (Retavase), and tenecteplase TNK-tPA (TNKase). Streptokinase and urokinase are enzymes that act systemically to promote the conversion of plasminogen to plasmin. Alteplase, also known as *tissue plasminogen activator (tPA),* is clot-specific and binds to the fibrin surface of a clot, promoting the conversion of plasminogen to plasmin. Plasmin, an enzyme, digests the fibrin in the clot. Plasmin also degrades fibrinogen, prothrombin, and other clotting factors. These five drugs all induce **fibrinolysis** (fibrin breakdown). Prototype Drug Chart 45-3 lists the pharmacologic data for alteplase.

Reteplase (Retavase) is a derivative of tPA. Anticoagulants and antiplatelet drugs increase the risk of hemorrhage; therefore they should be avoided until the thrombolytic effect has passed. The health care provider needs to determine whether the patient has taken any of these drugs before seeking treatment.

SAFETY: Preventing Medication Errors

Do not confuse…

Tenecteplase (TNKase) and **tissue plasminogen activator (tPA).** These two drugs look alike and are from the same class—thrombolytics—but they are different, and their dosages and administration time are different. TNKase is administered as a single dose; tPA is administered in three different doses and times. The first dose is a bolus, and the second and third doses are administered over 30 minutes and 60 minutes, respectively.

PROTOTYPE DRUG CHART 45-3

Alteplase (Tissue Plasminogen Activator [tPA])

Drug Class

Thrombolytic agent
Trade Names: Activase
Pregnancy Category: C

Dosage

A: IV bolus: 15 mg, then 50 mg infused over 30 min, then 35 mg infused over 60 min; *max:* 100 mg

Contraindications

Internal bleeding, bleeding disorders, recent CVA, surgery or trauma, bacterial endocarditis, severe liver dysfunction, severe uncontrolled hypertension, brain tumor, head trauma
Caution: Cardiac dysrhythmias, hepatic or renal disease

Drug-Lab-Food Interactions

Drug: Increase bleeding when taken with oral anticoagulants, NSAIDs, cefotetan, plicamycin; decrease effect when taken with nitroglycerin
Lab: Decrease in plasminogen, fibrinogen, hematocrit, and hemoglobin
Herbs: Increased bleeding with ginkgo biloba, garlic, feverfew, ginger, green tea

Pharmacokinetics

Absorption: Direct IV
Distribution: PB: UK
Metabolism: $t\frac{1}{2}$: 30-45 min
Excretion: Urine

Pharmacodynamics

PO: Onset: Immediate
Peak: 5-10 min
Duration: 3 h

Therapeutic Effects/Uses

To dissolve clot following acute MI, pulmonary embolism, acute ischemic stroke.
Mode of Action: Alteplase promotes conversion of plasminogen to plasmin. Plasmin, an enzyme, digests fibrin matrix of clots. Alteplase initiates fibrinolysis.

Side Effects

Bleeding, nausea, vomiting, fever

Adverse Reactions

Anaphylactoid reactions, laryngeal edema, angioedema; cholesterol microembolization (purple-toe syndrome, gangrenous digitus, hypertension, spinal cord infarction, MI, cerebral infarction, bowel infarction, rhabdomyolysis)
Life-threatening: Intracerebral hemorrhage, stroke, atrial or ventricular dysrhythmias, pulmonary edema

A, Adult; *CVA,* cerebrovascular accident; *IV,* intravenous; *PB,* protein-binding; *max,* maximum; *min,* minute; *NSAIDs,* nonsteroidal antiinflammatory drugs; *PO,* by mouth; $t\frac{1}{2}$, half-life; *tPA,* tissue plasminogen activator; *UK,* unknown.

Pharmacokinetics The commercial preparation of alteplase (tissue plasminogen activator [tPA]) is identical to natural human tPA, the enzyme that converts plasminogen to plasmin. Alteplase is initially administered as an IV bolus, then infused over 30 minutes, and then 60 minutes. A total dose of 100 mg is the recommended maximum; a larger dose could result in risk for intracranial bleeding. The half-life of alteplase (tPA) is 5 minutes, shorter than the half-life of streptokinase. Alteplase is very expensive but about the same as TNKase and reteplase. Allergic reactions to alteplase occur less frequently than to anistreplase and urokinase.

Pharmacodynamics Alteplase is similar to natural human tissue plasminogen activator (tPA). It promotes thrombolysis by converting plasminogen to plasmin. Plasmin degrades fibrin, fibrinogen, and factors V, VIII, and XII. Alteplase does not induce hypotension as streptokinase does. Peak action of Alteplase is 5 to 10 minutes. The duration of action is 3 hours.

Side Effects and Adverse Reactions. Allergic reactions can complicate thrombolytic therapy. Anaphylaxis (vascular collapse) occurs more frequently with streptokinase than with the other thrombolytics. If the drugs are administered through an intracoronary catheter after myocardial infarction, reperfusion dysrhythmia or hemorrhagic infarction at the myocardial necrotic area can result. The major complication of thrombolytic drugs is hemorrhage. The antithrombolytic drug aminocaproic acid (Amicar) is used to stop bleeding by inhibiting plasminogen activation, which inhibits thrombolysis.

Table 45-4 lists the thrombolytic drugs and their dosages, uses, and considerations.

Nursing Process
Patient-Centered Collaborative Care

Thrombolytics

Assessment

- Assess baseline vital signs for comparison with future values.
- Check baseline complete blood count (CBC), prothrombin time (PT), or international normalized ratio (INR) values before administration of thrombolytics.
- Obtain a medical and drug history. Contraindications for use of thrombolytics include recent cerebrovascular accident (CVA), active bleeding, severe hypertension, and anticoagulant therapy. Report if patient takes

TABLE 45-4 THROMBOLYTICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Thrombolytics		
reteplase, r-PA (Retavase)	A: IV bolus: 10 units over 2 min, then repeat 10 units in 30 min (total of 20 units)	For lysis of thrombi after AMI. Inhibits fibrin aspect of thrombus. Derivative of tPA (Alteplase). Considered more effective than tPA with less risk of hemorrhage. Pregnancy category: C; PB: UK; $t_{1/2}$: 13-16 min
tenecteplase, TNK-tPA (TNKase)	A: IV: *max:* 30-50 mg Note: Dose is based on body weight.	To reduce mortality associated with AMI. A "clot buster" that can be administered in 5 seconds in one dose. Pregnancy category: C; PB: UK; $t_{1/2}$: 11-138 min
alteplase (tPA, Activase)	See Prototype Drug Chart 45-3.	
urokinase (Abbokinase)	A: IV: LD: 4400 international units/kg diluted and infused over 10 min, then continuous infusion: 4400 international units/kg over 12 h	Same uses as streptokinase. Causes less allergic reaction but is more expensive than streptokinase. Not susceptible to antistreptokinase antibodies. May also be used for peripheral artery occlusion. Pregnancy category: B; PB: UK; $t_{1/2}$: 10-20 min
Plasminogen Inactivators		
aminocaproic acid (Amicar)	A: PO/IV: LD: 4-5 g first h Inf: 1-1.25 g/h for 8 h; *max:* 30 g/d	To control excessive bleeding from hyperfibrinolysis. Side effects include orthostatic hypotension, headache, and thrombophlebitis. Pregnancy category: C; PB: 0%; $t_{1/2}$: 1-2 h

A, Adult; *AMI,* acute myocardial infarction; *d,* day; *DVT,* deep vein thrombosis; *h,* hour; *inf,* infusion; *IV,* intravenous; *LD,* loading dose; *max,* maximum; *MI,* myocardial infarction; *min,* minute; *PB,* protein-binding; *PE,* pulmonary embolism; $t_{1/2}$, half-life; *tPA,* tissue plasminogen activator; *UK,* unknown.

aspirin or nonsteroidal antiinflammatory drugs (NSAIDs). Thrombolytics are contraindicated for patients with a recent history of traumatic injury, especially head injury.

Nursing Diagnoses

- Decreased cardiac output related to excessive bleeding
- Anxiety related to fear of the unknown secondary to coronary artery disease
- Impaired tissue integrity related to a thrombus or embolus secondary to heart attack, or stroke
- Risk for injury related to thrombus or embolus

Planning

- Patient's blood clot will be dissolved.
- Patient's vital signs will be monitored for stability during and after thrombolytic therapy.
- Patient will not have excessive bleeding from thrombolytic therapy.

Nursing Interventions

- Monitor vital signs. Increased pulse rate followed by decreased blood pressure usually indicates blood loss and impending shock. Record vital signs, and report changes.
- Observe for signs and symptoms of active bleeding from the mouth or rectum. Hemorrhage is a serious complication of thrombolytic treatment. Aminocaproic acid can be given as an intervention to stop bleeding.
- Examine patient for active bleeding for 24 hours after thrombolytic therapy has been discontinued: q15min for first hour, q30min until eighth hour, and then hourly.
- Observe for signs of allergic reaction to thrombolytics, such as itching, hives, flush, fever, dyspnea, bronchospasm, hypotension, and/or cardiovascular collapse.
- Avoid administering aspirin or NSAIDs for pain or discomfort when patient is receiving a thrombolytic. Acetaminophen can be substituted.
- Monitor electrocardiogram for presence of reperfusion dysrhythmias as blood clot is dissolving; antidysrhythmic therapy may be indicated.
- Avoid venipuncture/arterial sticks.

Patient Teaching

General

- Explain thrombolytic treatment to patient and family. Be supportive.

Side Effects

- Advise patient to report any side effects, such as lightheadedness, dizziness, palpitations, nausea, pruritus, or urticaria.

Evaluation

- Determine effectiveness of drug therapy: clot has dissolved, vital signs are stable, no signs or symptoms of active bleeding, and patient is pain free.

KEY WEBSITES

Anticoagulation: *www.acforum.org*

CRITICAL THINKING CASE STUDY

TM, a 57-year-old man, has thrombophlebitis in the right lower leg. IV heparin, 5000 units by bolus, was given. Following the IV bolus, heparin 5000 units given subQ q6h was prescribed. Other therapeutic means to decrease pain and alleviate swelling and redness were also prescribed. An aPTT test was ordered.

1. Was TM's heparin order within the safe daily dosage range?
2. What are the various methods for administering heparin?
3. Why was an aPTT test ordered? How would you determine whether TM is within the desired range? Explain your answer.

After 5 days of heparin therapy, TM was prescribed warfarin (Coumadin) 5 mg PO daily. An INR test was ordered.

4. What is the pharmacologic action of warfarin? Is the warfarin dose within the safe daily dosage range? Explain your answer.
5. What are the half-life and protein-binding for warfarin? If a patient takes a drug that is highly protein-bound, would there be a drug interaction? Explain your answer.
6. Why was an INR ordered for TM? What is the desired range?
7. What serious adverse reactions could result with prolonged use or large doses of warfarin?
8. What patient teaching interventions should the nurse include? List three interventions.
9. Months later, TM has hematemesis. What nursing action should be taken?

NCLEX STUDY QUESTIONS

1. A patient is placed on heparin, and the nurse acknowledges that heparin is effective for preventing clot formation in patients who have which disorder(s)? (Select all that apply.)
   a. Coronary thrombosis
   b. Acute myocardial infarction
   c. Deep vein thrombosis
   d. Hemorrhagic cerebrovascular accident (stroke)
   e. Disseminated intravascular coagulation
2. A patient who received heparin begins to bleed. The nurse anticipates that the health care provider will order which antidote?
   a. protamine sulfate
   b. vitamin K_1 (Mephyton)
   c. aminocaproic acid (Amicar)
   d. potassium chloride (KCl)
3. A patient is prescribed enoxaparin (Lovenox). The nurse knows that low–molecular-weight heparin has what kind of half-life?
   a. A longer half-life than heparin
   b. A shorter half-life than heparin
   c. The same half-life as heparin
   d. A four times shorter half-life than heparin
4. The nurse is teaching a patient about clopidogrel (Plavix). Which information will the nurse include in the patient's teaching plan?
   a. Constipation may occur.
   b. Hypotension may occur.
   c. Bleeding may increase when taken with aspirin.
   d. Normal dose is 25 mg tablet per day.
5. A patient had an orthopedic surgery and is prescribed dalteparin (Fragmin). What would the nurse teach the patient and/or family about this low–molecular-weight heparin (LMWH) before discharge?
   a. How to administer the medication intramuscularly
   b. PT and INR monitoring will be done weekly.
   c. Avoidance of green leafy vegetables is recommended.
   d. Watch for bleeding or excessive bruising.
6. A patient is being changed from an injectable anticoagulant to an oral anticoagulant. Which anticoagulant does the nurse realize is administered orally?
   a. enoxaparin sodium (Lovenox)
   b. warfarin (Coumadin)
   c. bivalirudin (Angiomax)
   d. lepirudin (Refludan)
7. A patient is taking warfarin 5 mg/day for atrial fibrillation. The patient's international normalized ratio (INR) is 3.8. The nurse would consider the INR to be what?
   a. Within normal range
   b. Elevated range
   c. Low range
   d. Low-average range
8. Cilostazol (Pletal) is being prescribed for a patient with coronary artery disease. The nurse understands that which is the major purpose for antiplatelet drug therapy?
   a. Dissolve the blood clot
   b. Decrease tissue necrosis
   c. Inhibit hepatic synthesis of vitamin K
   d. Suppress platelet aggregation

9. A patient is to undergo a coronary angioplasty. The nurse acknowledges that which drug is used primarily for preventing reocclusion of coronary arteries following coronary angioplasty?
   a. clopidogrel (Plavix)
   b. abciximab (ReoPro)
   c. warfarin (Coumadin)
   d. cilostazol (Pletal)

10. A patient is admitted to the emergency department with an acute myocardial infarction. Which drug does the nurse anticipate the health care provider to order for prevention of tissue necrosis following blood clot blockage in a coronary artery?
   a. heparin sodium
   b. clopidogrel (Plavix)
   c. alteplase (rPA, Activase)
   d. aminocaproic acid (Amicar)

- Key Points
- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Describe the action of the two main drug groups: antihyperlipidemics and peripheral vasodilators.
- Compare the side effects and adverse reactions of antihyperlipidemics.
- Differentiate the side effects and adverse reactions of peripheral vasodilators.
- Apply the nursing process, including patient teaching, for antihyperlipidemics and peripheral vasodilators.

antihyperlipidemics, p. 664
apolipoproteins, p. 665
chylomicrons, p. 665
high-density lipoprotein, p. 664
high-sensitivity C-reactive protein, p. 668
homocysteine, p. 666
hyperlipidemia, p. 664
lipoprotein, p. 664
low-density lipoprotein, p. 664
peripheral vasodilators, p. 664
very low-density lipoproteins, p. 664

Various drugs are used to maintain or decrease blood lipid concentrations and promote dilation of vessels. Drugs that lower blood lipids are called *antihyperlipidemics, antilipidemics, antilipemics,* and *hypolipidemics.* In this chapter, drugs used to lower lipoproteins are called **antihyperlipidemics. Peripheral vasodilators** are drugs that dilate vessels that have been narrowed by vasospasm.

LIPOPROTEINS

Lipids (cholesterol, triglycerides, and phospholipids) are bound in the inner shell of protein, which is a carrier that transports lipids in the bloodstream. When there is an excess of one or more lipids in the blood, the condition is known as **hyperlipidemia** or *hyperlipoproteinemia.* The four major categories of **lipoprotein** are **high-density lipoprotein** (HDL), **low-density lipoprotein** (LDL), **very low-density lipoprotein** (VLDL)**,** and chylomicrons. HDL, also known as "friendly" or "good" lipoprotein, is the smallest, most dense lipoprotein, meaning that it contains more protein and less fat than the others. The function of HDL is to remove cholesterol from the bloodstream and deliver it to the liver for excretion in bile. LDL, the "bad" lipoprotein, contains 50% to 60% of cholesterol in the bloodstream. With an elevated LDL,

TABLE 46-1 **LIPOPROTEIN GROUPS**

LIPOPROTEIN SUBGROUPS	COMPOSITION OF LIPOPROTEINS			
	PROTEIN (%)	CHOLESTEROL (%)	TRIGLYCERIDES (%)	PHOSPHOLIPIDS (%)
Chylomicrons	1-2	1-3	80-95	3-6
Very low density	6-10	8-20	45-65	15-20
Low density	15-20	50-60	4-8	16-20
High density	45-55	15-20	2-7	26-32

TABLE 46-2 **SERUM LIPID VALUES**

LIPIDS	DESIRABLE (mg/dL)	LEVEL OF RISK FOR CAD		
		LOW RISK (mg/dL)	MODERATE RISK (mg/dL)	HIGH RISK (mg/dL)
Cholesterol	150-200	200	200-240	>240
Triglycerides	40-150	Values vary with age	Values vary with age	>190
Lipoproteins				
LDL	<100	100-130	130-159	>160
HDL	>60	50-60	35-50	<35

CAD, Coronary artery disease; *HDL,* high-density lipoproteins; *LDL,* low-density lipoproteins.

there is greater risk for developing atherosclerotic plaques and heart disease. VLDL carries mostly triglycerides and less cholesterol. The **chylomicrons** are large particles that transport fatty acids and cholesterol to the liver. They are composed mostly of triglycerides. Table 46-1 presents the composition of the lipoproteins.

Serum cholesterol and triglyceride measurements are frequently part of a regular physical examination or readmission evaluation and are used as baseline test results. If the levels are high, a 12- to 14-hour fasting lipid profile may be ordered. When cholesterol, triglycerides, and LDL are elevated, the patient is at increased risk for coronary artery disease (CAD). Table 46-2 lists the various serum lipids and their reference values (normal serum levels) according to risk classification.

APOLIPOPROTEINS

Apolipoproteins are within the lipoprotein shell and contain apolipoprotein (apo) A-1, apoB, and apoE. The major component of apoA1 is HDL. The major component of apoB is LDL, which exists in two forms, apoB-100 and apoB-48. ApoB-100 has VLDL as well as LDL and is a better indicator of risk for coronary artery disease (CAD) than LDL alone.

NONPHARMACOLOGIC METHODS FOR CHOLESTEROL REDUCTION

Before drugs to lower LDL and raise HDL are prescribed, nondrug therapy should be initiated for decreasing cholesterol. Saturated fats and cholesterol in the diet should be reduced. Total fat intake should be 30% or less of caloric intake, and cholesterol intake should be 300 mg/d or less. The patient should be advised to read labels on containers and buy appropriate foods. Patients should choose lean meats, especially chicken and fish.

In many cases, diet alone will not lower blood lipid levels. Because 75% to 85% of serum cholesterol is endogenously (internally) derived, dietary modification alone will typically lower total cholesterol levels by only 10% to 30%. This and the fact that adherence to dietary restrictions is often short-lived explains why many patients do not respond to diet modification alone.

Exercise is an important aspect of the nonpharmacologic method to reduce cholesterol and increase HDL. For the older adult, exercise can be walking and bicycling. Smoking is another risk factor that should be eliminated. Smoking increases LDL cholesterol and decreases HDL.

If nonpharmacologic methods are ineffective for reducing cholesterol, LDL, and VLDL and hyperlipidemia remains, antihyperlipidemic drugs are prescribed to lower blood lipid levels. It must be emphasized to the patient that dietary changes need to be made and an exercise program followed even after drug therapy is initiated. The type of antihyperlipidemics ordered depends on the lipoprotein phenotype (Table 46-3).

ANTIHYPERLIPIDEMICS

Drugs that lower lipid levels include bile-acid sequestrants, fibrates (fibric acid), nicotinic acid, cholesterol absorption inhibitor, and hepatic 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase inhibitors (statins). The statins have fewer adverse effects and are well tolerated.

TABLE 46-3 **HYPERLIPIDEMIA: LIPOPROTEIN PHENOTYPE**

TYPE*	MAJOR LIPIDS
I	Increased chylomicrons and increased triglycerides. Uncommon.
IIA	Increased low-density lipoprotein (LDL) and increased cholesterol. Common.
IIB	Increased very low-density lipoprotein (VLDL), increased LDL, increased cholesterol and triglycerides. Very common.
III	Moderately increased cholesterol and triglycerides. Uncommon.
IV	Increased VLDL and markedly increased triglycerides. Very common.
V	Increased chylomicrons, VLDL, and triglycerides. Uncommon.

*Types II and IV are commonly associated with coronary artery disease.

One of the first antihyperlipidemics, cholestyramine (Questran), is a bile-acid sequestrant that reduces LDL cholesterol (LDL-C) levels by binding with bile acids in the intestine. It is effective against hyperlipidemia type II. This group may be used as an adjunct to the statins. The drug comes in a gritty powder, which is mixed thoroughly in water or juice. Colestipol (Colestid) is another resin antihyperlipidemic similar to cholestyramine. Both are effective in lowering cholesterol. Colesevelam HCl, another bile acid sequestrant similar to cholestyramine and colestipol, is an agent that has fewer side effects (less constipation, flatulence, and cramping). Colesevelam also has less effect on the absorption of fat-soluble vitamins than the older agents and is usually the first-choice bile-acid sequestrant drug.

Gemfibrozil (Lopid) is a fibric acid derivative that is more effective at reducing triglyceride and VLDL levels than reducing LDL. It is used primarily to reduce hyperlipidemia type IV, but it can also be used for type II hyperlipidemia. This drug is highly protein-bound and should not be taken with anticoagulants, because they compete for protein sites. The anticoagulant dose should be reduced during antihyperlipidemic therapy, and the international normalized ratio (INR) should be closely monitored. Fenofibrate has similar actions and some of the same side effects as gemfibrozil. If taken with warfarin, bleeding might occur. It is highly protein-bound.

Nicotinic acid, or niacin (vitamin B_3), reduces VLDL and LDL. Nicotinic acid is actually very effective at lowering cholesterol levels, and its effect on the lipid profile is highly desirable. Because it has numerous side effects and large doses are required, as few as 20% of patients can initially tolerate niacin. However, with proper counseling, careful drug titration, and concomitant use of aspirin, this number can be increased to as high as 60% to 70%.

Ezetimibe (Zetia) is a cholesterol absorption inhibitor that acts on the cells in the small intestine to inhibit cholesterol absorption. It decreases cholesterol from dietary absorption, reducing serum cholesterol, LDL, triglycerides, and apoB levels. Ezetimibe causes only a small increase in HDL. It must be combined with a statin for optimum effect (ezetimibe and simvastatin [Zocor], marketed as Vytorin).

Statins

The statin drugs inhibit the enzyme HMG CoA reductase in cholesterol biosynthesis; thus the statins are called *HMG CoA reductase inhibitors.* By inhibiting cholesterol synthesis in the liver, this group of antihyperlipidemics decreases the concentration of cholesterol, decreases LDL, and slightly increases HDL cholesterol. Reduction of LDL cholesterol may be seen as early as 2 weeks after initiating therapy. The statin group has been useful in decreasing CAD and reducing mortality rates.

Numerous statins have been approved since they were first introduced. The present group of statins includes atorvastatin calcium (Lipitor), fluvastatin (Lescol), lovastatin (Mevacor), pravastatin sodium (Pravachol), simvastatin (Zocor), and rosuvastatin calcium (Crestor). Lovastatin was the first statin used to decrease cholesterol. It is effective in lowering LDL (hyperlipidemia type II) within several weeks. Gastrointestinal (GI) disturbances, headaches, muscle cramps, and fatigue are early complaints. With all statins, serum liver enzymes should be monitored, and an annual eye examination is needed, because cataract formation may result. The patient should report immediately any muscle aches or weakness, which can lead to rhabdomyolysis, a muscle disintegration that can become fatal.

The statins have actions in decreasing serum cholesterol, LDL, VLDL, and triglycerides, and they slightly elevate HDL. Atorvastatin, lovastatin, and simvastatin are more effective at lowering LDL than the other statins. Atorvastatin and simvastatin are at the top of the list of most prescribed drugs in the United States.

The statin drugs can be combined with other drugs to decrease blood pressure and blood clotting and to enhance the antihyperlipidemic effect. Examples are Advicor (lovastatin and niacin), Caduet (atorvastatin and amlodipine), Vytorin (simvastatin and ezetimibe), and Liptruzet (ezetimibe and atorvastatin). Table 46-4 lists these combination drugs and their dosages, uses, and considerations.

If antihyperlipidemic therapy is withdrawn, cholesterol and LDL levels return to pretreatment levels. The patient taking an antihyperlipidemic drug should understand that antihyperlipidemic therapy is a lifetime commitment for maintaining a decrease in serum lipid levels. Abruptly stopping the statin drug could cause a threefold rebound effect that may cause death from acute myocardial infarction (AMI).

Laboratory Tests

Homocysteine reference values are 4 to 17 mmol/L (fasting). Homocysteine, an amino acid, is a by-product of protein and is found in eggs, chicken, beef, and cheddar cheese. A high level of homocysteine has been linked to cardiovascular disease, stroke, and the possibility of Alzheimer's disease. It may also promote blood clotting. It has been stated that an increase in serum homocysteine can damage the inner

TABLE 46-4 ANTIHYPERLIPIDEMICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Bile-Acid Sequestrants		
cholestyramine (Questran, Prevalite)	A: PO: 4 g 1-2 times/d; mix powder in 120-240 mL of fluid; *max:* 24 g/d C >6 y: PO: 80 mg/kg/d t.i.d.	For type II hyperlipoproteinemia (LDL). Decrease in LDL apparent in 1 week. Mix powder well in 4-6 oz fluid. Has no effect on VLDL and HDL, but could increase triglyceride levels. GI upset and constipation can occur. Vitamin A, D, or K deficiency may occur because of decreased GI absorption. Pregnancy category: C; PB: UK; t½: UK
colesevelam (Welchol)	A: PO: 3 tabs (625 mg/tab) b.i.d. or 6 tabs/d with meals	Cholesterol-lowering effect achieved by binding with bile salts in intestines to form insoluble complex with fecal excretions, reducing circulating cholesterol, including LDL. Triglycerides may be slightly increased. Contraindicated with bowel obstruction. May be used in combination with a statin drug. Pregnancy category: B; PB: UK; t½: UK
colestipol HCl (Colestid)	A: PO: 5-20 g/d in divided doses; *max:* 30 g/d	To reduce cholesterol and LDL levels. Same as cholestyramine. Pregnancy category: C; PB: UK; t½: UK
Fibrates (Fibric Acid)		
fenofibrate (TriCor)	A: PO: 48-145 mg/d; *max:* 148 mg/d	Treatment of type IV and V hyperlipidemia, and for hypertriglyceridemia. Specified diet should be part of drug therapy. Monitor serum creatinine levels. Pregnancy category: C; PB: 99%; t½: 20 h
gemfibrozil (Lopid)	A: PO: 600 mg b.i.d. 30 min before meals; *max:* 1,200 mg/d	For VLDL and elevated triglycerides; LDL may decrease, and HDL may increase. For types II (VLDL, LDL), III, IV, and V hyperlipidemia. Use in combination with lovastatin contraindicated because of increase in CPK. Pregnancy category: C; PB: 95%; t½: 1.5 h
Nicotinic Acid		
niacin (nicotinic acid) (Niaspan)	A: PO: Initially: 250 mg/d; maint: 1.5-2 g/d with meals in 3 divided doses; *max:* 6 g/d	For VLDL and LDL: types II, III, IV, and V hyperlipidemia. Doses are 100 times higher than RDA to lower VLDL. Pregnancy category: C; PB: <20%; t½: 45 min
Cholesterol Absorption Inhibitors		
ezetimibe (Zetia)	A/C >10 y: PO: 10 mg/d	Inhibits cholesterol absorption in small intestine. Reduces total cholesterol, LDL, and triglycerides. Increases HDL. Caution with liver dysfunction and elevated serum transaminase. Pregnancy category: C; PB: 90%; t½: 22 h
Statins (HMG-CoA Reductase Inhibitors)		
atorvastatin calcium (Lipitor)	A: PO: 10-40 mg/d; *max:* 80 mg/d	Treatment of dyslipidemia and hypercholesterolemia. Monitor liver enzymes for elevation. Pregnancy category: X; PB 98%; t½: 20-30 h
fluvastatin sodium (Lescol)	A: PO: Initially: 20-40 mg h.s.; maint: 20-80 mg/d; *max:* 80 mg/d	Treatment of types IIA and IIB hyperlipidemia, total cholesterol, and elevated triglycerides. HDL slightly increased. Monitor liver function (liver enzymes). Pregnancy category: X; PB: 98%; t½: 2.5 h
lovastatin (Mevacor)	A: PO: 10-20 mg/d with evening meal; *max:* 80 mg/d	Controls cholesterol by inhibiting cholesterol synthesis. Decreases LDL, increases some HDL. Monitor liver enzymes. Pregnancy category: X; PB: 95%; t½: 1-2 h
pravastatin sodium (Pravachol)	A: PO: 10-80 mg/d; *max:* 80 mg/d	Decreases serum cholesterol, LDL, VLDL, and triglycerides. HDL slightly increased. Monitor liver enzymes. Pregnancy category: X; PB: 50%; t½: 1.5-2.5 h
rosuvastatin calcium (Crestor)	See Prototype Drug Chart 46-1.	
simvastatin (Zocor)	A: PO: 5-40 mg/d in evening; *max:* 40 mg/d	Similar to lovastatin. Monitor liver enzymes. Pregnancy category: X; PB: 95%; t½: 2 h
pitavastatin (Livalo)	A: PO: Initially 2 mg/d; maint: 1-4 mg/d; *max:* 4 mg/d	Moderate reduction of LDLs and only modest increase in HDLs. May cause rhabdomyolysis. Monitor liver enzymes and muscle pain. Pregnancy category: X; PB: 99%; t½: 12 h
Miscellaneous Antilipemics		
icosapent ethyl (Vascepa)	A: PO: 2 g q12h; *max:* 4 g/d	For severe hypertriglyceridemia (triglyceride levels >500 mg/dL as an adjunct to diet. Monitor bleeding time for prolonged levels. Pregnancy category: C; PB: 99%; t½: 89 h
lomitapide (Juxtapid)	A: PO: 5 mg/d, may increase to 10 mg in 2 wks; *max:* 60 mg/d	For hypercholesterolemia. Most common adverse effects are GI disorders such as nausea, vomiting, abdominal pain, and diarrhea. Pregnancy category: X; PB: 99.8%; t½: 39.7 h
Omega 3 fatty acids (Lovaza)	A: PO: 4 g/d	For hypertriglyceridemia. Pregnancy category: C; PB: UK; t½: UK

TABLE 46-4 ANTIHYPERLIPIDEMICS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Combination Anticholesterol Drugs		
niacin and lovastatin (Advicor)	A: PO: 500 mg niacin/20 mg lovastatin Also available: 750 mg/20 mg; 1000 mg/20 mg; 1,000 mg/40 mg	Niacin raises HDL, triglycerides; lovastatin lowers LDL. Indicated for hypercholesterolemia and mixed dyslipidemia.
amlodipine and atorvastatin (Caduet)	A: PO: 2.5 mg amlodipine/20 mg atorvastatin/d; Also available: 2.5 mg/40 mg; 5 mg/10 mg to 5 mg/80 mg; 10 mg/10 mg to 10 mg/80 mg	Combination of calcium channel blocker and statin. Useful in treating hypertension and dyslipidemia. Helpful to patients who take these drugs separately.
ezetimibe/simvastatin (Vytorin)	A: PO: 10/10 mg to 10/80 mg	Combination of ezetimibe (Zetia) and simvastatin (Zocor). Ezetimibe decreases absorption of cholesterol in small intestine; simvastatin interferes with production of cholesterol in liver.
Ezetimibe and atorvastatin (Liptruzet)	A: PO: 10 mg daily	For hyperlipidemia. May cause increased ALT and AST. Pregnancy category: X; PB: 90%-98%; $t\frac{1}{2}$: 14 h

A, Adult; *a.c.,* before meals; *b.i.d.,* twice a day; *CPK,* creatine phosphokinase; *d,* day; *GI,* gastrointestinal; *h,* hour; *HDL,* high-density lipoprotein; *h.s.,* at bedtime; *LDL,* low-density lipoprotein; *maint,* maintenance; *max,* maximum; *min,* minute; *PB,* protein-binding; *p.c.,* after meals; *PO,* by mouth; *q.i.d.,* four times a day; *RDA,* recommended daily allowance; $t\frac{1}{2}$, half-life; *tab,* tablet; *t.i.d.,* three times a day; *UK,* unknown; *VLDL,* very low-density lipoprotein; *>,* greater than.

lining of blood vessels and promote a thickening and loss of flexibility in the vessel. Three vitamins that can lower serum homocysteine levels are vitamin B_6 (pyridoxine), vitamin B_{12} (cyanocobalamin), and folic acid.

High-sensitivity C-reactive protein (hsCRP) reference values are <0.175 mg/L; low risk are <1 mg/L; moderate risk are 1 to 3 mg/L; and high risk are >3 mg/L. The standard C-Reactive Protein (CP) is produced in the liver in response to tissue injury and inflammation. The hsCRP is a highly sensitive test for detecting the inflammatory protein that can be associated with cardiovascular and peripheral vascular disease. This test is frequently ordered along with cholesterol screen testing. Approximately one third of persons who have had a heart attack have normal cholesterol levels and normal blood pressure. A positive hsCRP test can indicate that the patient is at high risk for coronary artery disease (CAD), making it a valuable test for predicting CAD. This test can detect an inflammatory process caused by the buildup of atherosclerotic plaque in the arterial system, particularly the coronary arteries.

Prototype Drug Chart 46-1 lists the pharmacologic data for a frequently prescribed antihyperlipidemic, rosuvastatin.

Pharmacokinetics Rosuvastatin (Crestor) decreases LDL by 46% at a dose of 10 mg. It is highly protein-bound, so it usually is prescribed as a once-daily dose. Rosuvastatin has a half-life of 20 hours.

Pharmacodynamics The positive effect of lowering lipids with rosuvastatin is seen in about 2 weeks. The peak time after a dose of rosuvastatin is 3 to 5 hours; however, it takes 2 to 4 weeks to achieve therapeutic effect. When the patient is taking high doses of rosuvastatin or any statins, myopathy and rhabdomyolysis (disintegration of striated muscle fibers) may occur. If the patient complains of muscle pain or tenderness, it should be reported immediately.

Side Effects and Adverse Reactions. Side effects and adverse reactions of cholestyramine include constipation and peptic ulcer. Constipation can be decreased or alleviated by increasing intake of fluids and foods high in fiber. Early signs of peptic ulcer are nausea and abdominal discomfort, followed later by abdominal pain and distention. To avoid GI discomfort, the drug must be taken with and followed by sufficient fluids.

The many side effects of nicotinic acid (e.g., GI disturbances, flushing of the skin, abnormal liver function [elevated serum liver enzymes], hyperglycemia, hyperuricemia) decrease its usefulness. However, as mentioned, aspirin and careful drug titration can reduce side effects to a manageable level in most patients.

The statin drugs can cause a dose-related increase in liver enzyme levels. Serum liver enzyme levels (alkaline phosphatase, alanine aminotransferase, gamma-glutamyl transferase) should be monitored. Baseline liver enzyme studies should be obtained before initiating statin drug therapy. A slight transient increase in serum liver enzyme level may be within normal value for the patient, but it should be rechecked in 1 week or so. Patients with acute hepatic disorder should not take a statin drug.

The serious skeletal muscle adverse effect known as *rhabdomyolysis* has been reported with use of the statin drug class. Patients should be advised to promptly report to the health care provider any unexplained muscle tenderness or weakness, especially if accompanied by fever or malaise.

Table 46-4 lists the pharmacologic data for antihyperlipidemics.

PERIPHERAL VASODILATORS

A common problem in older adults is peripheral arterial (vascular) disease (PAD, PVD). It is characterized by numbness and coolness of the extremities, intermittent claudication (pain and weakness of limb when walking but no symptoms

PROTOTYPE DRUG CHART 46-1

Rosuvastatin

Drug Class Antihyperlipidemic: HMG-CoA reductase inhibitor Trade Name: Crestor Pregnancy Category: X	**Dosage** A: PO: 5-40 mg/d; *max:* 40 mg/d
Contraindications Active liver disease, pregnancy Caution: History of liver disease, increased alcohol ingestion, trauma, severe metabolic diabetes mellitus, uncontrolled seizures	**Drug-Lab-Food Interactions** Drug: Decrease effect with antacids, phenytoin, and propranolol. May increase digoxin level, oral contraceptives. Increase effects with macrolide antibiotics, antifungals
Pharmacokinetics Absorption: Rapid Distribution: PB: 88% Metabolism: t½: 20 h Excretion: Primarily in bile; some in urine	**Pharmacodynamics** PO: Onset: UK Peak: 3-5 h Duration: UK
Therapeutic Effects/Uses To decrease cholesterol levels and to decrease serum lipids, especially LDL and triglycerides Mode of Action: Inhibits HMG-CoA reductase, the enzyme necessary for hepatic production of cholesterol.	
Side Effects Rare. Headache, rash/pruritus, constipation, diarrhea	**Adverse Reactions** Rhabdomyolysis, myalgia, photosensitivity, hyperglycemia, elevated liver enzymes

A, Adult; *C,* child; *h,* hour; *HMG-CoA,* 3-hydroxy-3-methyl-glutaryl coenzyme A; *PO,* by mouth; *PB,* protein-binding; *t ½,* half-life; *LDL,* low-density lipoproteins.

at rest), and possible leg ulcers. The primary cause is arteriosclerosis and hyperlipidemia, resulting in atherosclerosis. The arteries become occluded.

Peripheral vasodilators increase blood flow to the extremities. They are used in peripheral vascular disorders of venous and arterial vessels. They are more effective for disorders resulting from vasospasm (Raynaud's disease) than from vessel occlusion or arteriosclerosis (arteriosclerosis obliterans, thromboangiitis obliterans [Buerger's disease]). In Raynaud's disease, cold exposure or emotional upset can trigger vasospasm of the toes and fingers; these patients have benefited from vasodilators. Patients with diabetes mellitus are more likely to have PAD by two to four times the usual rate and are at risk of intermittent claudication.

Papaverine (Para-Time SR) is a direct-acting peripheral vasodilator. The alpha-blocker prazosin (Minipress) and the calcium channel blocker nifedipine (Procardia) have also been used as peripheral vasodilators.

Individuals with PAD who are treated with HMG-CoA reductase inhibitors (statins) for dyslipidemia may get improvement for intermittent claudication symptoms as well as a decrease in serum lipids. Also, patients with PAD who are hypertensive receive improvement for both conditions when taking the antihypertensive drug ramipril (Altace), an ACE inhibitor. The antiplatelet drugs clopidogrel (Plavix) and aspirin have been used to decrease PAD symptoms. Another antiplatelet drug, cilostazol (Pletal), has been approved by the U.S. Food and Drug Administration (FDA) for treating intermittent claudication. It decreases arterial thrombi. The herb ginkgo biloba, taken with an antiplatelet drug, has been used to treat intermittent claudication, because of its vasodilating and antioxidant effects, although this herb has not been approved by the FDA. Most of the drugs used for treating PAD do not cure the health problem, but they can aid in relieving PAD symptoms.

Cilostazol is an antiplatelet that has a dual purpose of inhibiting platelet aggregation as well as causing vasodilation to treat intermittent claudication. Prototype Drug Chart 46-2 lists the pharmacologic data for cilostazol.

Nursing Process

Patient-Centered Collaborative Care

Antihyperlipidemics (Statins)

Assessment

- Assess vital signs and baseline serum chemistry values (cholesterol, triglycerides, aspartate aminotransferase [AST], alanine aminotransferase [ALT], and creatine phosphokinase [CPK]).
- Obtain a medical history. Statin drugs are contraindicated for patients with a liver disorder. Pregnancy category is X.

PROTOTYPE DRUG CHART 46-2

Cilostazol

Drug Class
Direct-acting vasodilator
Trade Name: Pletal
Pregnancy Category: C

Dosage
A: PO: 100 mg q12h 30 min before or 2 h after meals; max: 200 mg/d

Contraindications
Class III-IV congestive heart failure, hypersensitivity, bleeding disorders, thrombocytopenia
Caution: Bleeding disorders, liver and renal disease, leucopenia

Drug-Lab-Food Interactions
Drug: Increased effects with aspirin, cimetidine, clarithromycin, erythromycin, enoxaparin, ticlopidine, warfarin
Food: Grapefruit and green tea will increase levels; ginger and ginkgo biloba may prolong bleeding time.

Pharmacokinetics
Absorption: PO: Readily absorbed
Distribution: PB: 95%-98%
Metabolism: $t_{1/2}$: 11-13 h
Excretion: In urine (74%), feces (20%)

Pharmacodynamics
PO: Onset: 2-12 weeks
Peak: UK
Duration: UK

Therapeutic Effects/Uses
To treat peripheral vascular disease
Mode of Action: Acts directly to inhibit platelet aggregation and cause vasodilation, especially in femoral vasculature

Side Effects
Nausea, vomiting, dizziness, syncope, blood in eye, headache, abdominal pain, abnormal stools, peripheral edema

Adverse Reactions
Tachycardia, palpitations

A, Adult; *h,* hour; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *$t_{1/2}$,* half-life; *t.i.d.,* three times a day; *UK,* unknown.

Nursing Diagnoses

- Impaired tissue integrity related to atherosclerosis because of hyperlipidemia
- Anxiety related to elevated cholesterol level because of possible coronary artery disease
- Knowledge deficit related to inexperience with statin medications

Planning

- Patient's cholesterol level will be <200 mg/dL in 6 to 8 weeks.
- Patient will be able to choose foods low in fat, cholesterol, and complex sugars.

Nursing Interventions

- Monitor patient's blood lipid levels (cholesterol, triglycerides, LDL, and high-density HDL) every 6 to 8 weeks for first 6 months after statin therapy, then every 3 to 6 months. For lipid level profile, patient should fast for 12 to 14 hours. Desired cholesterol value is <200 mg/dL; triglyceride value is <150 mg/dL (can vary); LDL is <100 mg/dL; and HDL is >60 mg/dL. Cholesterol levels >240 mg/dL, LDL levels >160 mg/dL, and HDL levels <35 mg/dL can lead to severe cardiovascular event or cerebrovascular accident (CVA).
- Monitor laboratory tests for liver function (ALT, ALP, and gamma-glutamyl transferase [GGT]). Antihyperlipidemic drugs may cause liver disorder.
- Observe for signs and symptoms of GI upset. Taking the drug with sufficient water or with meals may alleviate some of the GI discomfort.

Patient Teaching

General

- Emphasize need to comply with drug regimen to lower blood lipids.
- Inform patient that it may take several weeks before blood lipid levels decline.
- Explain that laboratory tests for blood lipids (cholesterol, triglycerides, LDL, and HDL) are usually ordered every 3 to 6 months.
- Advise patient to have serum liver enzymes monitored as indicated by health care provider. Lovastatin, pravastatin, and simvastatin are contraindicated in acute hepatic disease and pregnancy.
- Instruct patient to have annual eye examination and to report changes in visual acuity.
- Advise patient taking gemfibrozil that it may increase risk for bleeding when concurrently taking oral anticoagulant, so bleeding should be reported. Drug dosage

can be changed or another antihyperlipidemic may be ordered.
- Instruct patients with diabetes or those at risk for developing diabetes to monitor blood glucose levels if they take gemfibrozil. Dietary changes or insulin adjustment may be necessary.
- Instruct patient to take nicotinic acid with meals to decrease GI discomfort.

Self-Administration
- Teach patient to mix cholestyramine/colestipol powder well in water or juice.

Side Effects of Cholestyramine, Colestipol, and Nicotinic Acid (Niacin)
- Advise patient that constipation may occur with cholestyramine and colestipol. Increasing fluid intake and food bulk should help alleviate the problem.
- Explain to patient that flush is common with niacin and should decrease with continued use of drug. Usually drug is started at a low dose.
- Advise patient that large doses of nicotinic acid can cause vasodilation, producing dizziness and faintness (syncope).

Side Effects of Ezetimibe
- Explain to patient that ezetimibe may cause headaches and GI upset. If it continues, notify the health care provider.

Side Effects of Statins
- Explain to patient that serum liver enzyme levels are periodically monitored.
- Encourage patient to report promptly any unexplained muscle tenderness or weakness that may be caused by rhabdomyolysis.
- Caution patient not to abruptly stop taking statin drug, because serious rebound effect might occur that could lead to AMI and possible death. Before stopping a statin, patient should talk to his or her health care provider.

Diet
- Explain to patient that GI discomfort is a common problem with most antihyperlipidemics. Suggest increasing fluid intake when taking medication.
- Encourage patient to maintain low-fat diet by eating foods that are low in animal fat, cholesterol, and complex sugars. Lovastatin and other antihyperlipidemics are adjuncts to, not substitutes for, a low-fat diet.

Cultural Considerations
- Respect patient's belief of how to control his or her cholesterol level.
- Avoid criticizing traditional practices. Explanations and modifications to plan of care may be necessary if method patient uses is not effective or is unsafe.

Evaluation
- Evaluate effectiveness of antihyperlipidemic drug. Patient's cholesterol level is within desired range.
- Determine that patient is on a low-fat, low-cholesterol diet.

Cilostazol

Pharmacokinetics Cilostazol is a direct-acting vasodilator that is absorbed from GI tract. It has a half-life of 11 to 13 hours. Cilostazol is usually taken two times a day.

Pharmacodynamics Cilostazol causes vasodilation of arteries, especially within the femoral vasculature. Common adverse effects include headache, diarrhea, and abnormal stools. This drug has an onset of action with 2 to 12 weeks.

Side Effects and Adverse Reactions. Lightheadedness, dizziness, tachycardia, palpitation, and GI distress may occur.

The effectiveness of peripheral vasodilators in increasing blood flow by vasodilation is questionable in the presence of arteriosclerosis. These drugs may decrease some of the symptoms of cerebrovascular insufficiency. Table 46-5 lists the peripheral vasodilators and their dosages, uses, and considerations.

Pentoxifylline

Pentoxifylline (Trental), classified as a *hemorrheologic agent,* improves microcirculation and tissue perfusion by decreasing blood viscosity and improving the flexibility of erythrocytes, thus increasing tissue oxygenation. It inhibits aggregation of platelets and red blood cells and helps increase flow through peripheral vessels, because it decreases blood viscosity. It is a derivative of the xanthine group. Pentoxifylline has been approved by the FDA for patients with intermittent claudication and has been prescribed for those with Buerger's disease resulting from arterial occlusions. However, in one research study, pentoxifylline was not determined to be more effective than a placebo.

Reactions to an overdose of pentoxifylline include flushing of the skin, faintness, sedation, and GI disturbances. The drug should be taken with food. The patient should avoid smoking, because nicotine increases vasoconstriction. Patients taking an antihypertensive drug along with pentoxifylline may need to have the antihypertensive dosage decreased to avoid side effects.

Nursing Process
Patient-Centered Collaborative Care

Vasodilators: Cilostazol

Assessment
- Obtain baseline vital signs for future comparison.
- Assess for signs of inadequate blood flow to the extremities: pallor, coldness of extremity, and pain.

TABLE 46-5 PERIPHERAL VASODILATORS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Direct-Acting Peripheral Vasodilators		
ergoloid mesylates	A: PO/SL: 1 mg t.i.d.; *max:* 3 mg/d	For cerebrovascular insufficiency. To improve cognitive skills, self-care, and mood, especially in the older adult. SL tablets should be placed under the tongue. May cause GI distress, orthostatic hypotension. Pregnancy category: X; PB: UK; t½: 2.6-5 h
Hemorrheologic		
cilostazol (Pletal)	See Prototype Drug Chart 46-2.	
pentoxifylline (Trental)	A: PO: 400 mg t.i.d. with meals	For peripheral vascular disorders. Alleviates intermittent claudication. Improves cerebral function for those with cerebrovascular insufficiency. May decrease stroke incidence for those having recurrent TIAs. Pregnancy category: C; PB: UK; t½: 0.5-1.8 h

A, Adult; *b.i.d.,* twice a day; *d,* day; *GI,* gastrointestinal; *h,* hour; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *SL,* sublingual; *t½,* half-life; *TIA,* transient ischemic attack; *t.i.d.,* three times a day; *UK,* unknown.

Nursing Diagnoses

- Impaired tissue integrity related to insufficient blood supply
- Acute pain related to inadequate blood flow to extremity

Planning

- Patient's blood flow to the extremities will improve, and patient's pain will be controlled.

Nursing Interventions

- Monitor vital signs, especially blood pressure and heart rate. Tachycardia and orthostatic hypotension can be problematic with peripheral vasodilators.

Patient Teaching

General

- Inform patient that a desired therapeutic response may take 1.5 to 3 months.
- Advise patient not to smoke; smoking increases vasospasm.
- Instruct patient to use aspirin or aspirin-like compounds only with the health care provider's approval. Salicylates help prevent platelet aggregation.

Side Effects

- Encourage patient to change position slowly but frequently to avoid orthostatic hypotension. Orthostatic hypotension is common when taking high doses of a vasodilator.
- Instruct patient to report side effects of cilostazol , such as flushing, headaches, and dizziness.

Diet

- Suggest that patient with GI disturbances take cilostazol with meals.
- Advise patient not to ingest alcohol with a vasodilator, because it may cause a hypotensive reaction.

Evaluation

- Evaluate effectiveness of cilostazol therapy; blood flow is increased in extremities, and pain has subsided.
- Patient experiences no side effects from the prescribed drug.

CRITICAL THINKING CASE STUDY

JH had a myocardial infarction (MI) 3 years ago. He was prescribed gemfibrozil (Lopid) 600 mg, twice daily, before meals. His cholesterol remained between 220 and 240 mg/dL, and his LDL was 140 mg/dL. His anticholesterol drug was changed to simvastatin (Zocor) 20 mg/day in the evening.

1. How does simvastatin differ from gemfibrozil?
2. Why do you think JH's cholesterol drug, gemfibrozil, was changed to simvastatin?
3. While JH is taking simvastatin, which group of serum levels should be monitored?
4. How long after JH took simvastatin should his cholesterol and lipoproteins be checked?
5. What is the maximum dose for simvastatin?
6. JH complains of muscle pain and muscle weakness. What might this indicate?
7. Could JH receive both gemfibrozil and simvastatin? Explain your answer.
8. JH is on vacation and does not have enough simvastatin tablets. What should he do?

NCLEX STUDY QUESTIONS

1. A patient has a serum cholesterol level of 265 mg/dL, triglyceride level of 235 mg/dL, and LDL of 180 mg/dL. What do these serum levels indicate?
    a. Hypolipidemia
    b. Normolipidemia
    c. Hyperlipidemia
    d. Alipidemia
2. The nurse knows that a patient's total cholesterol level should be within which range?
    a. 150 to 200 mg/dL
    b. 200 to 225 mg/dL
    c. 225 to 250 mg/dL
    d. >250 mg/dL
3. A patient has a low-density lipoprotein (LDL) of 175 mg/dL and a high-density lipoprotein (HDL) of 30 mg/dL. What teaching should the nurse implement for this patient?
    a. Discuss medications ordered, dietary changes, and exercise.
    b. No changes in lifestyle are needed and continue with current plan.
    c. Discuss how to have fat intake be 40% of caloric intake.
    d. Begin keeping a food diary and schedule lab work to be repeated in 6 months.
4. Which laboratory test value does the nurse realize can contribute to the development of cardiovascular disease and stroke?
    a. Decreased antidiuretic hormone
    b. Increased homocysteine level
    c. Decreased triglycerides
    d. Increased HDL level
5. A patient is taking lovastatin (Mevacor). Which serum level is most important for the nurse to monitor?
    a. Blood urea nitrogen
    b. Complete blood count
    c. Cardiac enzymes
    d. Liver enzymes
6. For what severe skeletal muscle adverse reaction should the nurse observe in a patient taking rosuvastatin (Crestor)?
    a. Myasthenia gravis
    b. Rhabdomyolysis
    c. Dyskinesia
    d. Agranulocytosis
7. A patient is taking ezetimibe (Zetia) and asks the nurse how it works. The nurse should explain that ezetimibe does what?
    a. Inhibits absorption of dietary cholesterol in the intestines.
    b. Binds with bile acids in the intestines to reduce LDL levels.
    c. Inhibits HMG-CoA reductase, which is necessary for cholesterol production in the liver.
    d. Forms insoluble complexes and reduces circulating cholesterol in the blood.
8. A patient is diagnosed with peripheral arterial disease. He is prescribed pentoxifylline (Trental). What does the nurse realize are the effects of pentoxifylline? (Select all that apply.)
    a. May lead to hypertension and bradycardia
    b. Improves microcirculation and tissue perfusion
    c. Decreases blood viscosity and improves flexibility of erythrocytes
    d. Alleviates intermittent claudication
    e. Commonly causes an adverse effect of rhabdomyolysis
    f. Allows vasodilation of arteries in skeletal muscles

Answers: 1, c; 2, a; 3, a; 4, b; 5, d; 6, b; 7, a; 8, b, c.

UNIT XV

Gastrointestinal Agents

The gastrointestinal (GI) system (tract), comprising the alimentary canal and the digestive tract, begins at the oral cavity and ends at the anus. Major structures of the GI system are (1) the oral cavity (mouth, tongue, and pharynx), (2) the esophagus, (3) the stomach, (4) the small intestine (duodenum, jejunum, and ileum), (5) the large intestine (cecum, colon, and rectum), and (6) the anus. The accessory organs and glands that contribute to the digestive process are (1) the salivary glands, (2) the pancreas, (3) the gallbladder, and (4) the liver (Figure XV-1). The main functions of the GI system are digestion of food particles and absorption of the digestive contents (nutrients, electrolytes, minerals, and fluids) into the circulatory system for cellular use. Digestion and absorption take place in the small intestine and to a lesser extent in the stomach. Undigested material passes through the lower intestinal tract with the aid of peristalsis to the rectum and anus, where it is excreted as feces, or stool.

ORAL CAVITY

The oral cavity, or mouth, starts the digestive process by (1) breaking up food into smaller particles; (2) adding saliva, which contains the enzyme amylase for digesting starch (the beginning of the digestive process); and (3) swallowing, a voluntary movement of food that becomes involuntary (peristalsis) in the esophagus, stomach, and intestines. Swallowing occurs in the pharynx (throat), which connects the mouth and esophagus.

ESOPHAGUS

The esophagus, a tube that extends from the pharynx to the stomach, is composed of striated muscle in its upper portion and smooth muscle in its lower portion. The inner lining of the esophagus is a mucous membrane that secretes mucus. The peristaltic process of contraction begins in the esophagus and ends in the lower large intestine. There are two sphincters, the superior esophageal (hyperpharyngeal) sphincter and the lower esophageal sphincter. The lower esophageal sphincter prevents gastric reflux into the esophagus, a condition called *reflux esophagitis.*

STOMACH

The stomach is a hollow organ that lies between the esophagus and the intestine. The body of the stomach has lesser and greater curvatures. It can hold 1000 to 2000 mL of gastric contents and empties in 2 to 6 hours (average is 3 to 4 hours), depending on gastric content and motility. Two sphincters, the *cardiac sphincter,* which lies at the upper opening of the stomach, and the *pyloric sphincter,* located at the lower portion of the stomach or the head of the duodenum, regulate the entrance of food into the stomach.

The interior lining of the stomach has mucosal folds that contain glands that secrete gastric juices. The four types of cells in the stomach mucosa that secrete these juices are (1) *chief cells,* which secrete the proenzyme pepsinogen (pepsin); (2) *parietal cells,* which secrete hydrochloric acid (HCl); (3) *gastrin-producing cells,* which secrete gastrin, a hormone that regulates enzyme release during digestion; and (4) *mucus-producing cells,* which release mucus to protect the stomach lining (which extends into the duodenum).

SMALL INTESTINE

The small intestine begins at the pyloric sphincter of the stomach and extends to the ileocecal valve at the cecum. Most drug absorption occurs in the duodenum, but lipid-soluble drugs and alcohol are absorbed from the stomach. The lower digestive process begins in the stomach, but most of the digestive contents are absorbed from the small intestine. The duodenum releases the hormone secretin, which suppresses gastric acid secretion, causing the intestinal juices to have a higher pH than the gastric juices. The intestinal cells also release the hormone cholecystokinin, which in turn stimulates the release of pancreatic enzymes and the contraction of the gallbladder to release bile into the duodenum. Hormones, bile, and pancreatic enzymes (trypsin, chymotrypsin, lipase, and amylase) complete the digestion of carbohydrates, protein, and fat in preparation for absorption.

LARGE INTESTINE

The large intestine accepts undigested material from the small intestine, absorbs water, secretes mucus, and with peristaltic contractions moves the remaining intestinal contents to the rectum for elimination. Defecation completes the process.

DRUGS FOR GASTROINTESTINAL DISORDERS

Vomiting, diarrhea, and constipation are GI problems that frequently require drug intervention. Chapter 47, Drugs for Gastrointestinal Tract Disorders, describes the antiemetics used to control vomiting. This chapter also discusses emetics used to eliminate ingested toxins and drugs, antidiarrheal drugs, and laxatives. The nursing process is considered in relation to each of these drug groups.

Chapter 48, Antiulcer Drugs, discusses drugs used to prevent and treat peptic ulcers (gastric and duodenal). These drugs include tranquilizers, anticholinergics, antacids, histamine$_2$ blockers, proton pump inhibitors, a pepsin inhibitor, and a prostaglandin analogue antiulcer drug.

OBJECTIVES

- Compare the pharmacologic treatment of vomiting, diarrhea, and constipation.
- Differentiate the actions and side effects of antiemetics, emetics, antidiarrheals, and laxatives.
- Apply the nursing process for the patient taking antiemetics, antidiarrheals, and laxatives.
- Differentiate contraindications to the use of antiemetics, emetics, antidiarrheals, and laxatives.

Drug groups used to correct or control vomiting, diarrhea, and constipation are antiemetics, emetics, antidiarrheals, and laxatives. Each of these drug groups is discussed separately. Drugs used to treat peptic ulcers are discussed in Chapter 48.

VOMITING

Vomiting (emesis), the expulsion of gastric contents, has a multitude of causes, including motion sickness, viral and bacterial infection, food intolerance, surgery, pregnancy, pain,

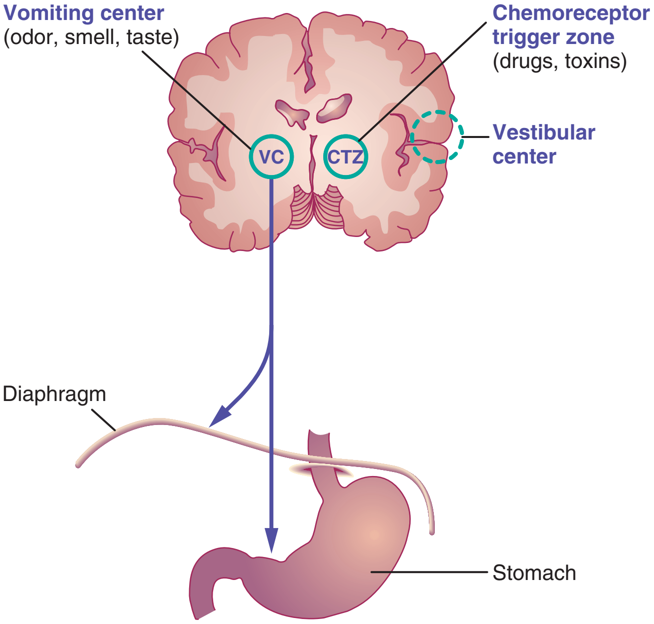

FIGURE 47–1 The chemoreceptor trigger zone and vomiting center.

shock, effects of selected drugs (e.g., antineoplastics), radiation, and disturbances of the middle ear that affect equilibrium. Nausea, a queasy sensation, may or may not precede the expulsion. The cause of the vomiting must be identified. Antiemetics can mask the underlying cause of vomiting and should not be used until the cause has been determined, unless the vomiting is so severe as to cause dehydration and electrolyte imbalance.

Two major cerebral centers—the **chemoreceptor trigger zone (CTZ),** which lies near the medulla, and the **vomiting center** in the medulla—cause vomiting when stimulated (Figure 47-1). The CTZ receives most of the impulses from drugs, toxins, and the vestibular center in the ear and transmits them to the vomiting center. The neurotransmitter dopamine stimulates the CTZ, which in turn stimulates the vomiting center. Levodopa, a drug with dopamine-like properties, can cause vomiting by stimulating the CTZ. Some sensory impulses, such as odor, smell, taste, and gastric mucosal irritation, are transmitted directly to the vomiting center. The neurotransmitter acetylcholine is also a vomiting stimulant. When the vomiting center is stimulated, the motor neuron responds by causing contraction of the diaphragm, the anterior abdominal muscles, and the stomach. The glottis closes, the abdominal wall moves upward, and vomiting occurs.

Nonpharmacologic measures should be used first when nausea and vomiting occur. If the nonpharmacologic measures are not effective, antiemetics are combined with nonpharmacologic measures. The two major groups of antiemetics are *nonprescription* (antihistamines, bismuth subsalicylate, and phosphorated carbohydrate solution) and *prescription* (antihistamines, dopamine antagonists, benzodiazepines, serotonin antagonists, glucocorticoids, cannabinoids, and miscellaneous antiemetics).

Nonpharmacologic Measures

The nonpharmacologic methods of decreasing nausea and vomiting include administration of weak tea, flat soda, gelatin, Gatorade, and Pedialyte (for use in children). Crackers and dry toast may be helpful. When dehydration becomes severe, intravenous (IV) fluids are needed to restore body fluid balance.

Nonprescription Antiemetics

Nonprescription **antiemetics** (antivomiting agents) can be purchased as over-the-counter (OTC) drugs. These drugs are frequently used to prevent motion sickness but have minimal effect on controlling severe vomiting resulting from anticancer agents (antineoplastics), radiation, and toxins. To prevent motion sickness, the antiemetic should be taken 30 minutes before travel. These drugs are not effective in relieving motion sickness if taken after vomiting has occurred.

Selected antihistamine antiemetics, such as dimenhydrinate (Dramamine), cyclizine hydrochloride (Marezine), meclizine hydrochloride (Antivert), and diphenhydramine hydrochloride (Benadryl) can be purchased OTC to prevent nausea, vomiting, and dizziness (vertigo) caused by motion. These drugs inhibit vestibular stimulation in the middle ear. Benadryl is also used to prevent or alleviate allergic reactions to drugs, insects, and food by acting as an antagonist to histamine$_1$ (H_1) receptors.

The side effects of antihistamine antiemetics are similar to those of anticholinergics: drowsiness, dryness of the mouth, and constipation. Table 47-1 lists the nonprescription antiemetics used for vomiting caused by motion sickness.

Several nonprescription drugs such as bismuth subsalicylate (Pepto-Bismol) act directly on the gastric mucosa to suppress vomiting. They are marketed in liquid and chewable tablet forms and can be taken for gastric discomfort or diarrhea. Phosphorated carbohydrate solution (Emetrol), a hyperosmolar carbohydrate, decreases nausea and vomiting by changing the gastric pH; it may also decrease smooth-muscle contraction of the stomach. Its effectiveness as an antiemetic has not been verified. Patients with diabetes mellitus should avoid this drug because of its high sugar content.

Antiemetics were once frequently used for the treatment of nausea and vomiting during the first trimester of pregnancy, but they are no longer recommended because they may cause harm to the fetus. Instead, nonpharmacologic methods should be used to alleviate nausea and vomiting during pregnancy, and OTC antiemetics should be avoided. If vomiting becomes severe and threatens the well-being of the mother and fetus, an antiemetic such as trimethobenzamide (Tigan) can be administered, although this drug is classified as *pregnancy category C.* Other antiemetics may be prescribed cautiously.

Prescription Antiemetics

Common prescription antiemetics are classified into the following groups: (1) antihistamines, (2) anticholinergics, (3) dopamine antagonists, (4) benzodiazepines, (5) serotonin antagonists, (6) glucocorticoids, (7) cannabinoids (for patients with cancer), and (8) miscellaneous. Many of these drugs act as antagonists to dopamine, histamine, serotonin, and acetylcholine, which are associated with vomiting. Antihistamines and anticholinergics act primarily on the vomiting center; they also act by decreasing stimulation of the CTZ and vestibular pathways. The cannabinoids act on the cerebral cortex. Phenothiazines, the miscellaneous antiemetics (e.g., metoclopramide), and trimethobenzamide act on the CTZ center. Drug combination therapy is commonly used to manage chemotherapy-induced nausea and vomiting. Lorazepam (Ativan), glucocorticoids, and serotonin (5-HT_3) receptor antagonists are quite effective in combination therapy. Lorazepam, haloperidol, and glucocorticoids are not approved by the U.S. Food and Drug Administration (FDA) as antiemetics but are extremely effective when combined for this unlabeled use.

Antihistamines and Anticholinergics

Only a few prescription antihistamines and anticholinergics are used in the treatment of nausea and vomiting. Table 47-2 lists these drugs and their dosages, uses, and considerations.

TABLE 47-1 NONPRESCRIPTION ANTIEMETICS: ANTIHISTAMINE

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Motion Sickness		
cyclizine HCl (Marezine)	A: PO: 50 mg q4-6 h; *max:* 200 mg/d C: 6-12 y: PO: 25 mg q6-8h; *max:* 75 mg/d	Used for prevention and treatment of nausea, vomiting, and motion sickness. Pregnancy category: B; PB: UK; t½: 13 h
dimenhydrinate (Dramamine)	A: PO: 50-100 mg q4-6h; *max:* 400 mg/d; IM/IV: 50 mg PRN; *max:* 300 mg/d C: 6-12 y: PO: 25-50 mg q6-8h PRN; *max:* 150 mg/d C: 2-5 y: 12.5-25 mg q6-8h PRN; *max:* 75 mg/d	Primarily used to prevent motion sickness. Drowsiness, dizziness, dry mouth, and hypotension may occur. Pregnancy category: B; PB: 78%; t½: 3.5 h
meclizine HCl (Antivert)	A/C: >12 y: PO: 25-50 mg 1 h before travel, after meal; may repeat q24h Vertigo: A: PO: 25-100 mg/d in divided doses	Prevention of nausea, vomiting, and dizziness. Drowsiness and dry mouth may occur. Pregnancy category: B; PB: UK; t½: 5-6 h

A, Adult; *C,* child; *d,* day; *h,* hour; *IM,* intramuscular; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *y,* year; *>,* greater than; *<,* less than.

TABLE 47-2 PRESCRIPTION ANTIEMETICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Prescription Antihistamines		
hydroxyzine (Vistaril)	A: PO/IM: 25-100 mg t.i.d./q.i.d. PRN; *max:* 400 mg/d C: IM: 1.1 mg/kg q4-6h	For postoperative nausea and vomiting and vertigo (dizziness). Given preoperatively with narcotics to decrease nausea. Give hydroxyzine deep IM. Drowsiness and dry mouth usually occur. Pregnancy category: X; PB: UK; t½: 14-25 h
promethazine (Phenergan)	See Prototype Drug Chart 47-1.	
Anticholinergics		
scopolamine (Transderm-Scōp)	A: transdermal patch: 1.5 mg (1 mg dose over 3 d); apply patch behind ear at least 4 h before antiemetic effect is required.	For motion sickness. Anticholinergic side effects (dizziness, drowsiness, dry mouth, constipation). Patch effective for 3 days. Alternate ears if using for longer than 3 days. Wash hands after applying disc/patch. Wear no more than one disc/patch at a time. Pregnancy category: C; PB: <25%; t½: 8 h
Dopamine Antagonists		
Phenothiazines		
prochlorperazine maleate (Compazine)	A: PO/IM: 5-10 mg t.i.d./q.i.d., PRN (give deep IM) SR: 10-15 mg q12h PR: 25 mg/b.i.d.; *max:* 40 mg/d C: PO/PR: 2.5 mg 1-3 times/d; *max:* 15 mg/d	Primary use is for severe nausea and vomiting. Secondary use is to reduce anxiety and tension and for psychosis. Drowsiness, dizziness, EPS, and dry mouth may occur. Pregnancy category: C; PB: 91%-99%; t½: 3-7 h
promethazine (Phenergan)	See Prototype Drug Chart 47-1.	

TABLE 47-2 **PRESCRIPTION ANTIEMETICS—cont'd**

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Butyrophenones		
droperidol (Inapsine)	A: IM/IV: 0.625-1.25 mg; C: 2-12 y: IM/IV: 0.1 mg/kg; *max:* 0.1 mg/kg	Prevention of nausea and vomiting during surgical and diagnostic procedures. May cause hypotension, tachycardia, and EPS. Black Box Warning: Not approved for patients with dementia-related psychosis. Pregnancy category: C; PB: UK: t½: 2.5 h
Benzodiazepines		
lorazepam (Ativan)	A: PO: 0.5-2 mg q4-6h PRN; *max:* 10 mg/d A: IV: 0.025 mg/kg C: IV: 0.05 mg/kg q6h PRN	For prevention of nausea and vomiting resulting from cancer chemotherapy. Usually administered with an antiemetic such as metoclopramide. Pregnancy category: D; PB: 91%; t½: 12 h
Serotonin (5-HT$_3$) Receptor Antagonists		
dolasetron mesylate (Anzemet)	Cancer chemotherapy: A/C: >2 y: PO: 100 mg, 1 h before chemotherapy A/C: >2 y: IV: 1.8 mg/kg 1 h before chemotherapy; Pre- and postoperatively: A: PO: 100 mg 2 h before surgery; IV: 12.5 mg 15 min before end of anesthesia; *max:* 100 mg	To prevent nausea and vomiting before chemotherapy or pre- and postoperatively. Acts on serotonin 5-HT$_3$ receptor in stomach and CTZ. Pregnancy category: B; PB: 69%-77%; t½: 10 min
granisetron (Kytril)	Cancer chemotherapy: A: PO: 1 mg b.i.d. (1 h before and 12 h after chemotherapy) A/C: >2 y: IV: 10 mcg/kg 30 min before chemotherapy	Prevention of nausea and vomiting caused by cancer chemotherapy. Acts on CTZ and vomiting center. Headache may occur. Pregnancy category: B; PB: 65%; t½: 5-12 h
ondansetron HCl (Zofran)	A: PO: 8-24 mg 30 min before chemotherapy, then q8h × 2 A/C: IV: 0.15 mg/kg 30 min before, then q4h × 2	For nausea and vomiting related to cancer chemotherapy, especially treatment with cisplatin. Pregnancy category: B; PB: 70%-76%; t½: 3-6 h
palonosetron (Aloxi)	A: IV: 0.25 mg over 30 sec, 30 min before chemotherapy	To prevent nausea and vomiting associated with cancer chemotherapy. Pregnancy category: B; PB: 52%; t½: 40 h
Cannabinoids		
dronabinol (Marinol) CSS III	Chemotherapy-induced nausea: A: PO: 5 mg/m^2 1-3 h before chemotherapy, then q2-4h after; *max:* 15 mg/m^2/dose	For nausea and vomiting caused by cancer chemotherapy. Taken before and for 24 hours after chemotherapy. Can be an appetite stimulant for patients with AIDS. Common side effects include drowsiness, dizziness, dry mouth, impaired thinking, and euphoria. Pregnancy category: C; PB: 98%; t½: 25-36 h
Miscellaneous		
metoclopramide HCl (Reglan)	Chemotherapy: IV: 1-2 mg/kg 30 min before chemotherapy; then q2h × 2; then q3h × 3 Postoperative: A: IM/IV: 10-20 mg at end of surgery	For nausea and vomiting related to cancer chemotherapy and postoperatively. Increases gastric and intestinal emptying. Avoid alcohol and CNS depressants. EPS may occur. Pregnancy category: B; PB: 30%; t½: 4-6 h
trimethobenzamide HCl (Tigan)	A: PO: 250-300 mg t.i.d./q.i.d. PRN; *max:* 1200 mg/d A: IM: 200 mg t.i.d./q.i.d. PRN; *max:* 800 mg/d	For postoperative nausea and vomiting, motion sickness, and vertigo. Avoid with CNS depressants and if sensitive to benzocaine or similar local anesthetics. Pregnancy category: C; PB: UK; t½: 7-9 h
aprepitant (Emend)	A: PO: 125 mg 1 h before chemotherapy on day 1, 80 mg on days 2 and 3 in the morning	For nausea and vomiting related to cancer chemotherapy. Pregnancy category: B; PB: 95%; t½: 9-13 h

A, Adult; *a.c.,* before meals; *AIDS,* acquired immunodeficiency syndrome; *b.i.d.,* two times a day; *C,* child; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *CTZ,* chemoreceptor trigger zone; *d,* day; *EPS,* extrapyramidal symptoms; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PR,* per rectum; *PRN,* as needed; *q.i.d.,* four times a day; *sec,* second; *SR,* sustained release; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *y,* year; *>,* greater than; *<,* less than.

Side Effects and Adverse Reactions. Side effects include drowsiness, which can be a major problem, dry mouth, blurred vision caused by pupillary dilation, tachycardia (with anticholinergic use), and constipation. These drugs should *not* be used by patients with glaucoma.

Dopamine Antagonists

These agents suppress emesis by blocking dopamine$_2$ receptors in the CTZ. The categories of dopamine antagonists include phenothiazines, butyrophenones, and benzodiazepines. Common side effects of dopamine antagonists are extrapyramidal symptoms (EPS), which are caused by blocking dopamine receptors, and hypotension. See Chapter 27 for a more detailed description of EPS and phenothiazines.

Phenothiazine Antiemetics

Selected piperazine phenothiazines are used to treat nausea and vomiting resulting from surgery, anesthetics, chemotherapy, and radiation sickness. They act by inhibiting the CTZ. When used in patients with cancer, these drugs are commonly given the night before treatment, the day of treatment, and for 24 hours after treatment. Not all phenothiazines are effective antiemetic agents. When prescribed for vomiting, the drug dosage is usually smaller than when used for psychiatric disorders.

Chlorpromazine (Thorazine) and prochlorperazine edisylate (Compazine) were the first phenothiazines used for both psychosis and vomiting. Promethazine (Phenergan), a phenothiazine introduced as an antihistamine in the 1940s, has a sedative effect and can also be used for motion sickness and management of nausea and vomiting. Promethazine is the most frequently prescribed antiemetic drug. Prototype Drug Chart 47-1 lists the pharmacologic data for promethazine.

Pharmacokinetics Promethazine is readily absorbed in the gastrointestinal (GI) tract. It has 93% protein-binding capacity. Promethazine is metabolized by the liver and excreted in urine and feces.

Pharmacodynamics Promethazine blocks H_1-receptor sites on effector cells and impedes histamine-mediated responses. The onset of

PROTOTYPE DRUG CHART 47-1

Promethazine HCl

Drug Class
Antiemetic: phenothiazine
Trade Name: Phenergan
Pregnancy Category: C

Dosage
A: PO/PR/IM/IV: 12.5-25 mg q4-6h PRN
C: >2 y: PO/PR/IM/IV: 0.25-1 mg/kg q4-6h PRN; *max:* 25 mg/dose

Contraindications
Hypersensitivity, narrow-angle glaucoma, severe liver disease, intestinal obstruction, blood dyscrasias, bone marrow depression
Caution: Cardiovascular disease, liver dysfunction, asthma, respiratory dysfunction, hypertension, older adults and debilitated patients

Drug-Lab-Food Interactions
Drug: Increases CNS depression and anticholinergic effects when taken with alcohol and other CNS depressants; lowers seizure threshold with phenytoin (Dilantin)
Lab: False pregnancy test

Pharmacokinetics
Absorption: PO: easily absorbed from GI tract
Distribution: PB: 93%
Metabolism: t½: 10-14 h
Excretion: In urine and feces

Pharmacodynamics
PO: Onset: 20 min
Peak: UK
Duration: 4-6 h
IM: Onset: 20 min
Peak: UK
Duration: 2-8 h
IV: Onset: 3-5 min
Peak: UK
Duration: 4-6 h
PR: Onset: 20 min
Peak: UK
Duration: 4-6 h

Therapeutic Effects/Uses
To treat and prevent motion sickness, nausea, and vomiting
Mode of Action: Blocks H_1 receptor sites; inhibits CTZ

Side Effects
Drowsiness, confusion, anorexia, dry mouth and eyes, constipation, blurred vision, photosensitivity, hypertension, hypotension, transient leukopenia, urinary retention

Adverse Reactions
Extrapyramidal syndrome (tardive dyskinesia, akathisia)
Life-threatening: Agranulocytosis, respiratory depression

A, Adult; *C,* child; *CNS,* central nervous system; *CTZ,* chemoreceptor trigger zone; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PR,* per rectum; *PRN,* as needed; *t ½,* half-life; *UK,* unknown; *y,* year.

action of oral and intramuscular (IM) administration is 20 minutes, and the duration of action is from 4 to 6 hours. The onset of action of intravenous (IV) promethazine is 3 to 5 minutes; the duration of action is the same as for the oral preparation.

Drug and Laboratory Interactions. Central nervous system (CNS) depression increases when promethazine is taken with alcohol, narcotics, sedative-hypnotics, and general anesthetics. Anticholinergic effects increase when promethazine is combined with antihistamines, anticholinergics such as atropine, and other phenothiazines. Promethazine may interfere with urinary pregnancy tests, producing false results.

Side Effects and Adverse Reactions. Phenothiazines have antihistamine and anticholinergic properties. The side effects of phenothiazine antiemetics are moderate sedation, hypotension, EPS, CNS effects (restlessness, weakness, dystonic reactions, agitation), and mild anticholinergic symptoms (dry mouth, urinary retention, and constipation). Because the dose is lower for vomiting than for psychosis, the side effects are not so severe. Promethazine is relatively free of EPS at antiemetic doses. Table 47-2 lists the pharmacologic data for phenothiazines and other prescription antiemetics.

Butyrophenones

Haloperidol (Haldol) and droperidol (Inapsine), like phenothiazines, block the dopamine$_2$ receptors in the CTZ. They are used to treat postoperative nausea and the vomiting and emesis associated with toxins, cancer chemotherapy, and radiation therapy. Antiemetic doses of haloperidol are smaller than those required for antipsychotic effects. Like phenothiazines, haloperidol and droperidol are likely to cause EPS if used for an extended time. Hypotension may result; therefore blood pressure should be monitored.

Benzodiazepines

Selected benzodiazepines indirectly control nausea and vomiting that may occur with cancer chemotherapy. Lorazepam (Ativan) is the drug of choice. Previously diazepam (Valium) was the preferred benzodiazepine. Lorazepam effectively provides emesis control, sedation, anxiety reduction, and amnesia when used in combination with a glucocorticoid and serotonin 5-HT$_3$ receptor antagonist.

Serotonin (5-HT$_3$) Receptor Antagonists

Serotonin antagonists suppress nausea and vomiting by blocking the serotonin receptors (5-HT$_3$) in the CTZ and the afferent vagal nerve terminals in the upper GI tract.

Serotonin antagonists—ondansetron (Zofran), granisetron (Kytril), dolasetron (Anzemet), and palonosetron (Aloxi)—are the most effective of all antiemetics in suppressing nausea and vomiting caused by cancer chemotherapy–induced emesis or emetogenic anticancer drugs. Ondansetron (the first serotonin antagonist), granisetron, and dolasetron do not block the dopamine receptors; therefore, they do not cause EPS as do the phenothiazine antiemetics. These drugs can be administered orally and IV. They are also effective in preventing nausea and vomiting before and after surgery. Common side effects include headache, diarrhea, dizziness, and fatigue.

Glucocorticoids (Corticosteroids)

Dexamethasone (Decadron) and methylprednisolone (Solu-Medrol) are two agents that are effective in suppressing emesis associated with cancer chemotherapy. Because these glucocorticoids are administered IV and for only a short while, side effects normally associated with glucocorticoids are minimized. Glucocorticoids are discussed in Chapter 51.

Cannabinoids

Cannabinoids, the active ingredients in marijuana, were approved for clinical use in 1985 to alleviate nausea and vomiting resulting from cancer treatment. These agents may be prescribed for patients receiving chemotherapy who do not respond to or are unable to take other antiemetics. They are contraindicated for patients with psychiatric disorders. Cannabinoids can be used as an appetite stimulant for patients with acquired immunodeficiency syndrome (AIDS). The cannabinoid dronabinol (Marinol) is described in Table 47-2.

Side Effects and Adverse Reactions. Side effects occurring as a result of cannabinoid use include mood changes, euphoria, drowsiness, dizziness, headaches, depersonalization, nightmares, confusion, incoordination, memory lapse, dry mouth, orthostatic hypotension or hypertension, and tachycardia. Less common symptoms are depression, anxiety, and manic psychosis.

Miscellaneous Antiemetics

Diphenidol (Vontrol) and trimethobenzamide (Tigan) are in the class of miscellaneous antiemetics, because they do not act strictly as antihistamines, anticholinergics, or phenothiazines. These drugs suppress impulses to the CTZ. Diphenidol also prevents vertigo by inhibiting impulses to the vestibular area.

Side Effects and Adverse Reactions. The side effects and adverse reactions of the miscellaneous antiemetics are drowsiness and anticholinergic symptoms (dry mouth, increased heart rate, urine retention, constipation, and blurred vision). Trimethobenzamide can cause hypotension, diarrhea, and EPS (abnormal involuntary movements, postural disturbances, and alteration in muscle tone).

Nursing Process

Patient-Centered Collaborative Care

Antiemetics

Assessment

- Determine a history of the onset, frequency, and amount of vomiting and contents of the vomitus. If appropriate, elicit from patient possible causative factors such as food (e.g., seafood, mayonnaise).

- Obtain a history of present health problems. Patients with glaucoma should avoid many of the antiemetics.
- Record vital signs for abnormalities and for future comparison.
- Assess urinalysis before and during therapy.

Nursing Diagnoses

- Imbalanced nutrition: less than body requirements related to inability to ingest food
- Risk for deficient fluid volume related to vomiting

Planning

- Patient will adhere to nonpharmacologic methods and/or drug regimen to alleviate vomiting.
- Patient's underlying cause of vomiting will be corrected.
- Patient will retain small amounts of food.

Nursing Interventions

- Check vital signs. If vomiting is severe, dehydration may occur, and shocklike symptoms may be present.
- Monitor bowel sounds for hypoactivity or hyperactivity.
- Provide mouth care after vomiting. Encourage patient to maintain oral hygiene.

Patient Teaching

General

- Instruct patient to store drug in airtight, light-resistant container if required.
- Tell patient to avoid OTC preparations.
- Warn patient not to consume alcohol while taking antiemetics. Alcohol can intensify sedative effect.
- Advise pregnant patients to avoid antiemetics during first trimester because of possible teratogenic effects on the fetus. Encourage these patients to seek medical advice about OTC or prescription antiemetics.

Side Effects

- Tell patient to report sore throat, fever, and mouth sores; notify health care provider and have blood drawn for complete blood count (CBC).
- Alert patient to avoid driving a motor vehicle or engaging in dangerous activities, because drowsiness is common with antiemetics. If drowsiness becomes a problem, a decrease in dosage may be indicated.
- Caution patient with hepatic disorder to seek medical advice before taking phenothiazines. Instruct patient to report dizziness.
- Suggest to patient nonpharmacologic methods of alleviating nausea and vomiting such as flat soda, weak tea, crackers, and dry toast.

Cultural Considerations

- Respect patients' cultural beliefs and alternative methods for treating nausea and vomiting. Discuss with patients the safety of their methods, other nondrug methods, and purpose of antiemetic if prescribed.
- Procure an interpreter to assist non–English-speaking patients to understand the drug schedule for prescribed antiemetics and their side effects when needed.

Evaluation

- Evaluate effectiveness of nonpharmacologic methods or antiemetic by noting absence of vomiting. Identify any side effects that may result from drug.

Metoclopramide

Metoclopramide (Reglan) suppresses emesis by blocking the dopamine receptors in the CTZ. It is used in the treatment of postoperative emesis, cancer chemotherapy, and radiation therapy. High doses can cause sedation and diarrhea. With this agent, the occurrence of EPS is more prevalent in children than in adults. Metoclopramide should not be given if the patient has GI obstruction, hemorrhage, or perforation.

Table 47-2 lists pharmacologic data for the miscellaneous antiemetics along with other prescription antiemetics.

SAFETY: Preventing Medication Errors

Do not confuse …

- **Antivert** (antiemetic) with **Axert** (antimigraine)
- **Lorazepam** (controls nausea and vomiting) with **alprazolam** (anxiolytic)
- **Hydroxyzine** (antiemetic) with **hydralazine** (antihypertensive)

EMETICS

Emetics are drugs used to induce vomiting. When an individual has consumed certain toxic substances, induced vomiting (emesis) may be indicated to expel the substance before absorption occurs. There are many ways to induce vomiting without using drugs, such as putting the finger in the back part of the throat.

Vomiting should not be induced if caustic substances, such as ammonia, chlorine bleach, lye, toilet cleaners, or battery acid, have been ingested. Regurgitating these substances can cause additional injury to the esophagus. To prevent aspiration, vomiting should also be avoided if petroleum distillates are ingested; these include gasoline, kerosene, paint thinners, and lighter fluid. Activated charcoal is given when emesis is contraindicated.

Ipecac

Administration of ipecac has diminished greatly but it is still used when indicated. The American Academy of Clinical Toxicology and the European Association of Poisons Centres and Clinical Toxicologists issued guidelines in 2004 that ipecac syrup should not be administered routinely in the management of poisoned individuals; no new guidelines have

TABLE 47-3 EMETICS AND ADSORBENTS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Emetics		
ipecac syrup (OTC preparation)	A: PO: 15-30 mL, followed by 8-16 oz of water C: 1-12 y: PO: 15 mL, followed by 8-16 oz of water C: 6-11 mo: PO: 5-10 mL, followed by 4-8 oz of water	Induces vomiting after poisoning. Administer within 60 minutes of poisoning to an alert and conscious individual. Pregnancy category: C; PB: NA; t½: 2 h
Adsorbents		
charcoal (CharcoAid, CharcoCaps)	For poisoning, use CharcoAid: A: PO: 30-100 g in 6-8 oz of water C: PO: 1-2 g/kg in 6-8 oz of water C: <1 y: PO: 1 g/kg	Promotes absorption of poison/toxic substances. Neither drug is systemically absorbed. Pregnancy category: C; PB: NA; t½: NA

A, Adult; *C,* child; *CNS,* central nervous system; *d,* day; *max,* maximum; *mo,* month; *NA,* not applicable; *OTC,* over-the-counter; *PB,* protein-binding; *PO,* by mouth; *PRN,* as necessary; *t½,* half-life; *y,* year.

been issued since 2004. Ipecac is considered appropriate in isolated cases for the patient who is alert and if administered within 60 minutes of poisoning.

When the patient purchases ipecac, instruct the patient to buy ipecac *syrup* and *not* ipecac fluid extract, which is more potent and may cause fatalities. When ipecac is kept in the household, it should be kept out of the reach of children. Ipecac syrup induces vomiting by stimulating the CTZ in the medulla and acting directly on the gastric mucosa. Ipecac should be taken with a glass of water (do not give with milk or carbonated beverages). The onset of emesis production following administration of ipecac syrup is usually 15 to 30 minutes. When vomiting is not induced, patients should be treated with an adsorbent, such as activated charcoal, or gastric lavage (Table 47-3). Individuals with bulimia and anorexia nervosa often abuse ipecac, which may lead to cardiomyopathy, ventricular fibrillation, and death.

DIARRHEA

Diarrhea (frequent liquid stool) is a symptom of an intestinal disorder. Causes include (1) foods (spicy, spoiled), (2) fecal impaction, (3) bacteria *(Escherichia coli, Salmonella)* or viruses (parvovirus, rotavirus), (4) toxins, (5) drug reaction, (6) laxative abuse, (7) malabsorption syndrome caused by lack of digestive enzymes, (8) stress and anxiety, (9) bowel tumor, and (10) inflammatory bowel disease such as ulcerative colitis or Crohn's disease. Diarrhea can be mild to severe. Antidiarrheals should not be used for more than 2 days and should not be used if fever is present.

Because intestinal fluids are rich in water, sodium, potassium, and bicarbonate, diarrhea can cause minor or severe dehydration and electrolyte imbalances. The loss of bicarbonate places the patient at risk for developing metabolic acidosis. Patients with diarrhea should avoid milk products and foods rich in fat. Diarrhea can develop very quickly and can be life threatening to young patients and older adults, who may not be able to compensate for the fluid and electrolyte losses.

Nonpharmacologic Measures

The cause of diarrhea should be identified. Nonpharmacologic treatment for diarrhea is recommended until the underlying cause can be determined. This includes use of clear liquids and oral solutions (Gatorade; Pedialyte or Rehydralyte [both for use in children]) and IV electrolyte solutions. Antidiarrheal drugs are frequently used in combination with nonpharmacologic treatment.

Traveler's Diarrhea

Traveler's diarrhea, also called *acute diarrhea,* is usually caused by *E. coli.* It ordinarily lasts less than 2 days; however, if it becomes severe, fluoroquinolone antibiotics are usually prescribed. Loperamide (Imodium) may be used to slow peristalsis and decrease the frequency of defecation, but it can also slow the exit of the organism from the GI tract. Traveler's diarrhea can be reduced by drinking bottled water, washing fruit, and eating cooked vegetables. Meats should be cooked until well done.

Antidiarrheals

There are various **antidiarrheals** for treating diarrhea and decreasing hypermotility (increased peristalsis). Usually there is an underlying cause of the diarrhea that needs to be corrected as well. The antidiarrheals are classified as (1) opiates and opiate-related agents, (2) somatostatin analogue, (3) adsorbents, and (4) miscellaneous antidiarrheals.

Opiates and Opiate-Related Agents

Opiates decrease intestinal motility, thereby decreasing peristalsis. Constipation is a common side effect of opium preparations. Codeine is an example. Opiates are frequently combined with other antidiarrheal agents. Opium antidiarrheals can cause CNS depression when taken with alcohol, sedatives, or tranquilizers. The duration of action of opiates is approximately 2 hours.

Diphenoxylate with atropine (Lomotil) is an opiate that has less potential for causing drug dependence than other opiates such as codeine. Difenoxin (Motofen) is an active metabolite of diphenoxylate, but it is more potent than

PROTOTYPE DRUG CHART 47-2

Diphenoxylate with Atropine

Drug Class Antidiarrheal Trade Name: Lomotil Pregnancy Category: C CSS V	**Dosage** A: PO: 2.5-5 mg t.i.d./q.i.d. PRN C: 2-12 y: PO: 0.3-0.4 mg/kg/d in 4 divided doses
Contraindications Severe diarrhea due to poisoning or pseudomembranous colitis Severe hepatic or renal disease, glaucoma, severe electrolyte imbalance; children <2 y	**Drug-Lab-Food Interactions** Drug: Increase CNS depression with alcohol, antihistamines, opioids, sedative-hypnotics; MAOIs may enhance hypertensive crisis Lab: Increase serum liver enzymes, amylase
Pharmacokinetics Absorption: PO: Well absorbed Distribution: PB: UK Metabolism: t½: 3-14 h Excretion: In feces and urine	**Pharmacodynamics** PO: Onset: 45-60 min Peak: 2 h Duration: 3-4 h
Therapeutic Effects/Uses To treat diarrhea by slowing intestinal motility Mode of Action: Inhibits gastric motility	
Side Effects Drowsiness, dizziness, constipation, dry mouth, weakness, flush, rash, blurred vision, mydriasis, urine retention	**Adverse Reactions** Angioedema Life-threatening: Paralytic ileus, toxic megacolon, severe allergic reaction

A, Adult; *b.i.d.,* twice a day; *C,* child; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *h,* hour; *MAOIs,* monoamine oxidase inhibitors; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PRN,* as necessary; *q.i.d.,* four times a day; *t ½,* half-life; *UK,* unknown; *y,* year; *>,* greater than; *<,* less than.

diphenoxylate. Both drugs are combined with atropine to decrease abdominal cramping, intestinal motility, and hypersecretion. Diphenoxylate with atropine (Lomotil) is frequently prescribed for traveler's diarrhea, and difenoxin with atropine (Motofen) is prescribed to treat nonspecific and chronic diarrhea. With prolonged use of these drugs, physical dependence may occur. Diphenoxylate antidiarrheal products are approximately 50% atropine, which will discourage drug abuse. Prototype Drug Chart 47-2 lists the parmacologic data for diphenoxylate with atropine (Lomotil).

Loperamide (Imodium) is structurally related to diphenoxylate but causes less CNS depression than diphenoxylate and difenoxin. It can be purchased as an OTC drug, and it protects against diarrhea, reduces fecal volume, and decreases intestinal fluid and electrolyte losses.

Patients with severe hepatic impairment should not take products containing diphenoxylate, difenoxin, or loperamide. Children and older adults who take diphenoxylate are more susceptible to respiratory depression than other age groups.

Pharmacokinetics Diphenoxylate with atropine is well absorbed from the GI tract. The diphenoxylate is metabolized by the liver mainly as metabolites. There are two half-lives: 3 hours for diphenoxylate and 3 to 14 hours for the diphenoxylate metabolites. The drug is excreted in the feces and urine.

Pharmacodynamics Diphenoxylate with atropine is an opium agonist with anticholinergic properties (atropine); it decreases GI motility (peristalsis). It has a moderate onset of action of 45 to 60 minutes, and the duration of action is 3 to 4 hours. Many side effects are caused by the anticholinergic atropine. Patients with severe glaucoma should take another antidiarrheal that does not have an anticholinergic effect. If this drug is taken with alcohol, narcotics, or sedative-hypnotics, CNS depression can occur.

Adsorbents

Adsorbents act by coating the wall of the GI tract and adsorbing bacteria or toxins that cause diarrhea. Adsorbent antidiarrheals include kaolin and pectin. These agents are combined as a mild or moderate antidiarrheal that can be purchased OTC and used in combination with other antidiarrheals. Bismuth subsalicylate (Pepto-Bismol) is considered an adsorbent because it adsorbs bacterial toxins. Pepto-Bismol can also be used as an antacid for gastric discomfort. Pepto-Bismol is an OTC drug commonly used to treat traveler's diarrhea. Colestipol and cholestyramine (Questran) are prescription drugs that have been used to treat diarrhea due to excess bile acids in the colon. They are effective, although they have not been approved by the FDA for this purpose. Table 47-4 lists the pharmacologic data for antidiarrheal adsorbents.

Miscellaneous Antidiarrheals

Various miscellaneous antidiarrheals are prescribed to control diarrhea. This group includes rifaximin. Table 47-4 includes these other antidiarrheals.

TABLE 47-4 ANTIDIARRHEALS: OPIATES AND OPIATE-RELATED, ADSORBENTS, AND MISCELLANEOUS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Opiates and Opiate-Related		
deodorized opium tincture CSS II	A: PO: 0.6-1 mL q.i.d. mixed with water; *max:* 6 mL/d C: PO: 0.005-0.01 mL/kg q3-4 h; *max:* 6 doses/d	For acute, nonspecific diarrhea. To treat withdrawal symptoms in neonates of mothers who are addicted to opiates. Not recommended for diarrhea caused by poison. Avoid taking alcohol and CNS depressants. Pregnancy category: C; PB: UK; t½: 2-3 h
difenoxin and atropine (Motofen) CSS IV	A: PO: Initially: 2 mg; then 1 mg after each loose stool; *max:* 8 mg/d for 2 d	For acute nonspecific and chronic diarrhea. Combination of a synthetic narcotic and atropine. Avoid use in patients with narrow-angle glaucoma. Dry mouth, flush, and tachycardia may occur. Pregnancy category: C; PB: UK; t½: 12-24 h
loperamide HCl (Imodium)	A: PO: Initially: 4 mg; then 2 mg after each loose stool; *max:* 16 mg/d C: 9-11 y: PO: 2 mg t.i.d. on day 1, then 0.1 mg/kg after unformed stool; *max:* 6 mg/d C: 6-8 y: PO: 2 mg b.i.d. on day 1, then 0.1 mg/kg after unformed stool; *max:* 4 mg/d	For diarrhea. Newest OTC drug. Does not affect CNS. Less than 1% reaches systemic circulation. Pregnancy category: C; PB: 97%; t½: 11-24 h
Adsorbents		
bismuth subsalicylate (Pepto-Bismol, Kapectolin, Kaopectate)	A: PO: 2 tab or 30 mL q30-60 min PRN; *max:* 8 doses/d	For diarrhea, gastric distress. OTC liquid and tab form. Pregnancy category: C; PB: UK; t½: UK
kaolin-pectin (Kaolin with Pectin)	A: 60-120 mL after each loose stool C: 6-12 y: 30-60 mL after each loose stool	For diarrhea. Administer after each loose stool. OTC drug. Pregnancy category: C; PB: UK; t½: UK
Miscellaneous		
rifaximin (Xifaxan)	A: PO: 200 mg t.i.d. for 3 days	For treatment of travelers' diarrhea caused by noninvasive strains of *E. coli*. Pregnancy category: C; PB: 67.5%; t½: 5-6 h

CONSTIPATION

Constipation (accumulation of hard fecal material in the large intestine) is a relatively common complaint and a major problem for older adults. Insufficient water intake and poor dietary habits are contributing factors. Other causes include (1) fecal impaction, (2) bowel obstruction, (3) chronic laxative use, (4) neurologic disorders (paraplegia), (5) ignoring the urge to defecate, (6) lack of exercise, and (7) selected drugs, such as anticholinergics, narcotics, and certain antacids.

Nursing Process
Patient-Centered Collaborative Care

Antidiarrheals

Assessment

- Obtain a history of any viral or bacterial infection, drugs taken, and foods ingested that could be contributing factors to diarrhea. Many antidiarrheals are contraindicated if patient has liver disease, narcotic dependence, ulcerative colitis, or glaucoma.
- Check vital signs to provide baseline for future comparison and to determine body fluid and electrolyte losses.
- Determine frequency and consistency of bowel movements.
- Assess bowel sounds. Hyperactive sounds can indicate increased intestinal motility.
- Report if patient has a narcotic drug history. If opiate or opiate-related antidiarrheals are given, drug misuse or abuse may occur.

Nursing Diagnoses

- Diarrhea related to laxative abuse
- Imbalanced nutrition: less than body requirements related to misconceptions regarding OTC drugs
- Risk for imbalanced fluid volume related to diarrhea

Planning

- Patient will have bowel movements that are formed.
- Patient's body fluids will be restored.

Nursing Interventions

- Record vital signs. Report tachycardia or systolic blood pressure decrease of 10 to 15 mm Hg. Monitor respirations. Opiates and opiate-related drugs can cause central nervous system (CNS) depression.
- Monitor frequency of bowel movements and bowel sounds. Notify health care provider if intestinal hypoactivity occurs when taking drug.
- Check for signs and symptoms of dehydration resulting from persistent diarrhea. Fluid replacement may be necessary. With prolonged diarrhea, check serum electrolytes.
- Administer antidiarrheals cautiously to patients with glaucoma, liver disorders, or ulcerative colitis and to pregnant patients.
- Recognize that drug may need to be withheld if diarrhea continues for more than 48 hours or acute abdominal pain develops.

Patient Teaching

- Instruct patient not to take sedatives, tranquilizers, or other narcotics with drug. CNS depression may occur.
- Tell patient to avoid OTC preparations (they may contain alcohol promoting liver damage and concurrent use with loratadine and loperamide may lead to significant interaction).
- Advise patient to take the drug only as prescribed. Drug may be habit-forming; do not exceed recommended dose.
- Encourage patient to drink clear liquids.
- Advise patient not to ingest fried foods or milk products until diarrhea has stopped.
- Teach patient that constipation can result from overuse of antidiarrheal drugs.

Cultural Considerations

- Do not assume that lack of eye contact means that patient is not listening or does not care. It might indicate respect. The more traditional and older individuals in some cultures may not maintain eye contact.

Evaluation

- Evaluate the effectiveness of the drug; diarrhea has stopped.
- Monitor long-term use of opiates and opiate-related drugs for possible abuse and physical dependence.
- Continue to monitor vital signs. Report abnormal changes.

Nonpharmacologic Measures

Nonpharmacologic management includes diet (high fiber), water, exercise, and routine bowel habits. A "normal" number of bowel movements ranges between one and three per day to three per week. What is normal varies from person to person; the nurse should determine what normal bowel habits are for each patient. At times a laxative may be needed, but the patient should also use nonpharmacologic measures to prevent constipation.

Laxatives

Laxatives and **cathartics** are used to eliminate fecal matter. Laxatives promote a soft stool, cathartics result in a soft to watery stool with some cramping, and frequently dosage determines whether a drug acts as a laxative or cathartic. Because these terms are often used interchangeably, *laxative* will cover both classes in this chapter. **Purgatives** are "harsh" cathartics that cause a watery stool with abdominal cramping. There are four types of laxatives: (1) osmotics (saline), (2) stimulants (contact or irritants), (3) bulk-forming, and (4) emollients (stool softeners).

Laxatives should be avoided if there is any question that the patient may have intestinal obstruction; if abdominal pain is severe; or if symptoms of appendicitis, ulcerative colitis, or diverticulitis are present. Most laxatives stimulate peristalsis. Laxative abuse from chronic use is a common problem, especially in older adults. Laxative dependence can become a problem, so patient teaching is an important nursing responsibility.

Osmotic (Saline) Laxatives

Osmotics (hyperosmolar laxatives) include salts or saline products, lactulose, and glycerin. Saline products consist of sodium or magnesium, and a small amount is systemically absorbed. Serum electrolytes should be monitored to avoid electrolyte imbalance. Hyperosmolar salts pull water into the colon and increase water in the feces to increase bulk, which stimulates peristalsis. Saline cathartics cause a semiformed to watery stool according to low or high doses. Good renal function is needed to excrete any excess salts. Saline cathartics are contraindicated for patients with heart failure.

Osmotic laxatives contain electrolyte salts, including (1) sodium salts (sodium phosphate or Phospho-Soda, sodium biphosphate) and (2) magnesium salts (magnesium hydroxide [milk of magnesia], magnesium citrate). High doses of salt laxatives are used for bowel preparation for diagnostic and surgical procedures. Another laxative used for bowel preparation is polyethylene glycol (PEG) with electrolytes, marketed as GoLYTELY. With PEG, however, a large volume of solution, approximately 3 to 4 liters over 3 hours, must be ingested. Patients may be advised to keep GoLYTELY refrigerated to make it more palatable. The positive aspect is that the solution is an isotonic, nonabsorbable osmotic substance that contains sodium salts and potassium chloride; thus it can be used by patients with renal impairment or cardiac disorder.

Lactulose, another saline laxative that is not absorbed, draws water into the intestines to form a soft stool. It decreases the serum ammonia level and is useful in liver diseases, such as cirrhosis. Glycerin acts like lactulose, increasing water in the feces in the large intestine. The bulk that results from the increased water in the feces stimulates peristalsis and defecation.

Side Effects and Adverse Reactions. Adequate renal function is needed to excrete excess magnesium. Patients who have renal insufficiency should avoid magnesium salts. Hypermagnesemia can result from continuous use of magnesium salts, causing symptoms such as drowsiness, weakness, paralysis, complete heart block, hypotension, flush, and respiratory depression.

The side effects of excess lactulose use include flatulence, diarrhea, abdominal cramps, nausea, and vomiting. Patients who have diabetes mellitus should avoid lactulose, because it contains glucose and fructose.

Stimulant (Contact) Laxatives

Stimulant (contact or irritant) laxatives increase peristalsis by irritating sensory nerve endings in the intestinal mucosa. Types include those containing bisacodyl (Dulcolax), senna (Senokot), and castor oil (purgative). Bisacodyl is the most frequently used and abused laxative and can be purchased OTC. Bisacodyl and several others of these drugs are used to empty the bowel before diagnostic tests (barium enema). Prototype Drug Chart 47-3 lists the pharmacologic data for the stimulant laxative bisacodyl.

Castor oil is a harsh laxative (purgative) that acts on the small bowel and produces a watery stool. The action is quick, within 2 to 6 hours, so the laxative should not be taken at bedtime. Castor oil is seldom used to correct constipation. It is used mainly for bowel preparation.

Pharmacokinetics The contact laxative bisacodyl is minimally absorbed from the GI tract. It is excreted in feces, but because of the small amount of bisacodyl absorption, a portion is excreted in urine.

Pharmacodynamics Bisacodyl promotes defecation. Bisacodyl irritates the colon, causing defecation, and psyllium compounds increase fecal bulk and peristalsis. The onset of action of oral bisacodyl occurs within 6 to 8 hours, and with the suppository (rectal administration) it occurs within 15 to 60 minutes.

Side Effects and Adverse Reactions. Side effects include nausea, abdominal cramps, weakness, and reddish brown urine caused by excretion of phenolphthalein, senna, or cascara.

With excessive and chronic use of bisacodyl, fluid and electrolyte (especially potassium and calcium) imbalances are likely to occur. Systemic effects occur infrequently, because absorption of bisacodyl is minimal. Mild cramping and diarrhea are side effects of bisacodyl.

Castor oil should not be used in early pregnancy, because it stimulates uterine contraction. Spontaneous abortion may result. Prolonged use of senna can damage nerves, which may result in loss of intestinal muscular tone. Table 47-5 lists the osmotic and stimulant laxatives with their dosages, uses, and considerations.

PROTOTYPE DRUG CHART 47-3

Bisacodyl

Drug Class
Laxative: stimulant
Trade Name: Dulcolax
Pregnancy Category: C

Dosage
A: PO: 5-15 mg PRN; *max:* 30 mg
C: >6 y: PO: 5-10 mg
A/C: 6 y: rectal supp: 10 mg/d
C: >2 y: 5 mg

Contraindications
Hypersensitivity, fecal impaction, intestinal/biliary obstruction, GI bleeding, appendicitis, abdominal pain, nausea, vomiting, rectal fissures

Drug-Lab-Food Interactions
Drug: Decrease effect with antacids, histamine$_2$ blockers, proton pump inhibitors
Food: milk

Pharmacokinetics
Absorption: Minimal (5%-15%)
Distribution: PB: UK
Metabolism: $t_{1/2}$: UK
Excretion: In bile and urine

Pharmacodynamics
PO: Onset: 6-8 h
Peak: N/A
Duration: N/A
PR: Onset: 15-60 min
Peak: N/A
Duration: N/A

Therapeutic Effects/Uses
Short-term treatment for constipation; bowel preparation for diagnostic tests
Mode of Action: Increases peristalsis by direct effect on smooth muscle of intestine

Side Effects
Anorexia, nausea, vomiting, cramps, diarrhea

Adverse Reactions
Dependence, hypokalemia
Life-threatening: Tetany

A, Adult; *C,* child; *d,* day; *h,* hour; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PR,* per rectum; *PRN,* as needed; *supp,* suppository; $t_{1/2}$, half-life; *UK,* unknown; *y,* year; >, greater than; <, less than.

TABLE 47-5 LAXATIVES: OSMOTICS (SALINE), STIMULANTS, AND SELECTIVE CHLORIDE CHANNEL ACTIVATOR

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Osmotics: Saline		
glycerin	A: Supp: 1 supp into rectum; retain 15 min C: <6 y: supp: 1 infant supp	For constipation. Use with caution in patients with cardiac, renal, or liver disease and for older adults or dehydrated patients. Pregnancy category: C; PB: UK; t½: 30-45 min
lactulose (Cephulac, Chronulac)	Chronic constipation: A: PO: 15-30 mL/d, may increase to 60 mL/d PRN	For constipation. Also used in liver disease for ammonia elimination. May be used for constipation after barium studies. Poorly absorbed. Pregnancy category: B; PB: UK; t½: UK
magnesium citrate (Citroma)	A: PO: 150-300 mL in single or divided dose C: 6-12 y: PO: 100-150 mL in single or divided dose C: 2-5 y: PO: 60-120 mL in single or divided dose	For constipation or to complete bowel elimination before diagnostic procedures and surgery. Pregnancy category: B; PB: UK; t½: UK
magnesium hydroxide (milk of magnesia)	A: PO: 15-60 mL/d C: 6-11 y: PO: 15-30 mL/d C: 2-5 y: PO: 5-15 mL/d	For constipation. Take with a glass of water in morning or evening. With frequent use, good renal function is necessary. Pregnancy category: B; PB: UK; t½: UK
magnesium oxide (Mag-Ox)	A: PO: 2-4 g h.s. with 8 oz water	Similar to magnesium hydroxide. Contraindicated in patients with renal failure. Pregnancy category: A; PB: UK; t½: UK
sodium biphosphate (Fleet Phospho-Soda)	A: PO: 15-30 mL mixed in water Enema: A: 60-120 mL C: 30-60 mL	For constipation or bowel preparation. Contraindicated in patients with HF. Pregnancy category: C; PB: UK; t½: UK
Stimulants		
bisacodyl (Dulcolax)	See Prototype Drug Chart 47-3.	
castor oil (Neoloid, Purge)	A: PO: 15-60 mL/d C: 2-12 y: 5-15 mL/d	For bowel preparation for diagnostic tests. Harsh cathartic or purgative. Not commonly used for constipation. Pregnancy category: X; PB: UK; t½: UK
senna (Senokot)	A: PO: 1-2 tab or 1-2 tsp (granules) diluted in water; *max:* 4 tab/d	For constipation. Available in granules, syrup, and suppository. Prolonged use may cause fluid and electrolyte imbalances. Flatus and abdominal cramps may occur. Pregnancy category: C; PB: UK; t½: UK
Selective Chloride Channel Activator		
lubiprostone (Amitiza)	A: PO: 24 mcg b.i.d.	For treatment of chronic idiopathic constipation in adults. Pregnancy category: C; PB: 94%; t½: 0.9-1.4 h

A, Adult; *b.i.d.,* twice a day; *C,* child; *HF,* heart failure; *h.s.,* at bedtime; *d,* day; *h,* hour; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *supp,* suppository; *t½,* half-life; *tab,* tablet; *tsp,* teaspoon; *UK,* unknown; *y,* year; *>,* greater than; *<,* less than.

Bulk-Forming Laxatives

Bulk-forming laxatives are natural fibrous substances that promote large, soft stools by absorbing water into the intestine, increasing fecal bulk and peristalsis. These agents are nonabsorbable. Defecation usually occurs within 8 to 24 hours; however, it may take up to 3 days after drug therapy is started for the stool to be soft and well formed. Powdered bulk-forming laxatives, which sometimes come in flavored and sugar-free forms, should be mixed in a glass of water or juice, stirred, drunk immediately, and followed by a half to a full glass of water. Insufficient fluid intake can cause the drug to solidify in the GI tract, which can result in intestinal obstruction. This group of laxatives does not cause laxative dependence and may be used by patients with diverticulosis, irritable bowel syndrome, and ileostomy and colostomy.

Polycarbophil (FiberCon), polyethylene glycol (MiraLax), methylcellulose (Citrucel), and psyllium (Metamucil) are examples of bulk-forming laxatives. Patients with hypercalcemia should avoid calcium polycarbophil because of the significant amount of calcium in the drug. Prototype Drug Chart 47-4 lists the pharmacologic data for the bulk-forming laxative psyllium (Metamucil).

Pharmacokinetics The bulk-forming laxative Metamucil is a nondigestible and nonabsorbent substance that, when mixed with water, becomes a viscous solution. Because it is not absorbed, there is no protein-binding or half-life for the drug. Metamucil is excreted in the feces.

Pharmacodynamics The onset of action for Metamucil is 12 to 72 hours. Peak action is 1 to 3 days. The duration of action is unknown.

Side Effects and Adverse Reactions. Bulk-forming laxatives are not systemically absorbed; therefore there is no systemic effect. If bulk-forming laxatives are excessively used, nausea, vomiting, flatus, or diarrhea may occur. Abdominal cramps may occur if the drug is used in dry form.

PROTOTYPE DRUG CHART 47-4

Psyllium

Drug Class Laxative: bulk forming Trade Name: Metamucil Pregnancy Category: B	**Dosage** A: PO: 1-2 tsp in 8 oz water followed by 8 oz water 1-3 times/d C: >6 y: PO: 0.5-1 tsp in 8 oz water, followed by at least 4 oz water 1-3 times/d
Contraindications Hypersensitivity, fecal impaction, intestinal obstruction, abdominal pain, GI bleeding, dysphagia, appendicitis	**Drug-Lab-Food Interactions** Drug: Decrease absorption of oral anticoagulants, aspirin, and digoxin
Pharmacokinetics Absorption: Not absorbed Distribution: PB: NA Metabolism: $t\frac{1}{2}$: NA Excretion: In feces	**Pharmacodynamics** PO: Onset: 12-72 h Peak: 1-3 d Duration: UK
Therapeutic Effects/Uses To control chronic constipation Mode of Action: Acts as bulk-forming laxative by drawing water into intestine	
Side Effects Anorexia, nausea, vomiting, cramps, flatulence, diarrhea	**Adverse Reactions** Esophageal or intestinal obstruction if not taken with adequate water Life-threatening: Bronchospasm, anaphylaxis

A, Adult; *C,* child; *d,* day; *h,* hour; *NA,* not applicable; *PB,* protein-binding; *PO,* by mouth; *$t\frac{1}{2}$,* half-life; *tsp,* teaspoon; *UK,* unknown; *y,* year; *>,* greater than; ≥, greater than or equal to.

Chloride Channel Activators

Selective chloride channel activators are a new category of laxatives used to treat idiopathic constipation in adults. The first drug in this category is lubiprostone, manufactured by Sucampo Pharmaceuticals. Lubiprostone was approved by the FDA in January 2006. This drug activates chloride channels in the lining of the small intestine, leading to an increase in intestinal fluid secretion and motility. By enhancing the passage of stool, lubiprostone relieves constipation, as well as accompanying symptoms of abdominal discomfort, pain, and bloating. Lubiprostone is contraindicated for patients with a history of mechanical GI obstruction, Crohn's disease, diverticulitis, and severe diarrhea. Adverse effects of lubiprostone include nausea, which seems to be dose-dependent, diarrhea, headache, abdominal distention, and flatulence.

Emollients (Stool Softeners)

Emollients are lubricants and stool softeners (surface-acting or wetting drugs) used to prevent constipation. These drugs decrease straining during defecation. Lubricants such as mineral oil increase water retention in the stool. Mineral oil absorbs essential fat-soluble vitamins A, D, E, and K. Some of the minerals can be absorbed into the lymphatic system.

Stool softeners work by lowering surface tension and promoting water accumulation in the intestine and stool. They are frequently prescribed for patients after myocardial infarction or surgery. They are also given before administration of other laxatives in treating fecal impaction. Docusate calcium (Surfak), docusate sodium (Colace), and docusate sodium with senna (Peri-Colace) are examples of stool softeners.

Side Effects and Adverse Reactions. Side effects of mineral oil include nausea, vomiting, diarrhea, and abdominal cramping. This laxative is not indicated for children, older adults, or patients with debilitating diseases, because they might aspirate the mineral oil, resulting in lipid pneumonia. The docusate group of drugs may cause mild cramping.

Contraindications. Contraindications to the use of laxatives include inflammatory disorders of the GI tract (appendicitis, ulcerative colitis, undiagnosed severe pain that could be caused by inflammation within the intestine [diverticulitis, appendicitis]), pregnancy, spastic colon, or bowel obstruction. Laxatives are contraindicated when any of these conditions is suspected. Table 47-6 lists the laxatives and their dosages, uses, and considerations.

Nursing Process

Patient-Centered Collaborative Care

Laxative: Stimulant

Assessment

- Obtain a history of constipation and possible causes (insufficient water or fluid intake, diet deficient in bulk

TABLE 47-6 LAXATIVES: BULK FORMING, EMOLLIENTS, AND EVACUANTS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Bulk Forming		
polycarbophil (FiberCon)	A: PO: 1 g 1-4 times/d; *max:* 6 g/d C: 6-12 y: PO: 500 mg/d 1-4 times/d; *max:* 2 g C: 2-5 y: PO: 500 mg 1-2 times/d; *max:* 1 g/d	For prevention of constipation. Also used to treat acute nonspecific diarrhea or diarrhea associated with irritable bowel syndrome. For diarrhea, absorbs water and produces formed stool. For constipation, chew tablet and follow with a full glass of water. Pregnancy category: C; PB: NA; t½: NA
polyethylene glycol (MiraLax, GoLytely)	A: PO: 17 g (1 Tbsp) in 4-8 oz water qd; *max:* 1 week C: >6 months: PO: 0.5-1.5 g/kg qd; *max:* 17 g/d, 2 weeks	For constipation. May be used for bowel preparation. Pregnancy category: C; PB: NA; t½: NA
methylcellulose (Citrucel)	A: PO: 5-20 mL t.i.d. in 8-10 oz of water C: 5-10 mL b.i.d. with 8 oz of water	For constipation. Effects similar to Metamucil. Mix in at least 8 oz of water, and take immediately. Pregnancy category: C; PB: NA; t½: NA
psyllium hydrophilic mucilloid (Metamucil)	See Prototype Drug Chart 47-4.	
Emollient: Stool Softeners		
docusate calcium; docusate sodium (Surfak, Dialose, Colace)	Docusate calcium: A: PO: 240 mg/d Docusate sodium: A: PO: 50-300 mg/d C: 2-12 y: 50-150 mg/d	For prevention of constipation. Stool softener. Acts on small and large intestines; little absorption. When first used, may take 1-5 days for effect. Available with calcium, potassium, or sodium. Pregnancy category: C; PB: NA; t½: NA
docusate sodium with senna (Peri-Colace)	A: PO: 2-4 tabs/d C: PO: 1-2 tabs/d C: PO: 1 tab/d	For prevention of constipation. Combination drug: docusate sodium 100 mg with casanthranol 30 mg. Pregnancy category: C; PB: NA; t½: NA
Emollient: Lubricant		
mineral oil (Kondremul Plain)	A: PO: 15-45 mL h.s.	For constipation and fecal impaction. May be useful for those with cardiac disorders and following anorectal surgery. Avoid prolonged use because vitamins A, D, E, and K may be lost. Pregnancy category: UK; PB: NA; t½: NA
Evacuant/Bowel Preparation		
polyethylene glycol-electrolyte solution (GoLYTELY)	Preparation for GI examination requires 3-4 h; fasting A: PO: 240 mL q10-15min for total of 4 L	For bowel preparation before GI examination. Pregnancy category: C; PB: NA; t½: NA

A, Adult; *b.i.d.,* twice a day; *C,* child; *HF,* heart failure; *h.s.,* at bedtime; *d,* day; *h,* hour; *GI,* gastrointestinal; *max,* maximum; *min,* minute; *NA,* not applicable; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *tab,* tablet; *t.i.d.,* three times a day; *UK,* unknown; *y,* year; *>,* greater than.

or fiber, inactivity), frequency and consistency of stools, and general health status.
- Record baseline vital signs for identification of abnormalities and for future comparison.
- Evaluate renal function.
- Assess electrolyte balance of patients who frequently use laxatives.

Nursing Diagnoses
- Constipation related to ignoring urge to defecate
- Risk for deficient fluid volume related to diuretic therapy
- Deficient knowledge related to overuse of laxatives
- Ineffective health maintenance related to lack of ability to make thoughtful judgments

Planning
- Patient will have a normal bowel elimination pattern.
- Patient will exercise, eat foods high in fiber, and have adequate fluid intake to avoid constipation.

Nursing Interventions
- Monitor fluid intake and output.
- Note signs and symptoms of fluid and electrolyte imbalances that may result from watery stools. Habitual use of laxatives can cause fluid volume deficit, electrolyte losses, and loss of urge to defecate.

Patient Teaching
General
- Encourage patient to increase water intake (if not contraindicated), which will decrease hard, dry stools.

- Advise patient to avoid overuse of laxatives, which can lead to fluid and electrolyte imbalances and drug dependence. Suggest exercise to help increase peristalsis.
- Teach patient not to chew tablets but to swallow them whole.
- Direct patient to store suppositories at less than 86° F (30° C).
- Council patient to take drug only with water to increase absorption.
- Educate patient not to take drug within 1 hour of any other drug.
- Warn patient that drug is not for long-term use; bowel tone may be lost.
- Encourage patient to time administration of drug so as not to interfere with activities or sleep.

Side Effects

- Advise patient to discontinue use if rectal bleeding, nausea, vomiting, or cramping occurs.

Diet

- Inform patient to increase foods high in fiber, such as bran, whole grains, and fruits.

Cultural Considerations

- Provide explanation and written information as needed related to the use and abuse of stimulant laxatives. Respect values and beliefs of patients from various cultural groups, and incorporate their traditional practices into treatment plan when possible.

Evaluation

- Determine effectiveness of nonpharmacologic methods for alleviating constipation.
- Evaluate patient's use of laxatives in managing constipation. Identify laxative abuse.

Nursing Process
Patient-Centered Collaborative Care

Laxative: Bulk Forming

Assessment

- Obtain a history of constipation and possible causes (insufficient water or fluid intake, diet deficient in bulk or fiber, inactivity), frequency and consistency of stools, and general health status.
- Record baseline vital signs for identification of abnormalities and for future comparisons.
- Assess renal function, urine output, blood urea nitrogen (BUN), and serum creatinine.

Nursing Diagnoses

- Constipation related to inadequate fiber in diet
- Risk for deficient fluid volume related to overuse of laxatives

Planning

- Patient will have a normal bowel elimination pattern.
- Patient will exercise, eat foods high in fiber, and have adequate fluid intake to avoid constipation.

Nursing Interventions

- Check fluid intake and output. Note signs and symptoms of fluid and electrolyte imbalances that may result from watery stools. Habitual use of laxatives can cause fluid volume deficit and electrolyte losses.
- Monitor bowel sounds.
- Identify cause of constipation.
- Avoid inhalation of psyllium dust.

Patient Teaching

General

- Teach patient to mix drug with water immediately before use to avoid GI obstruction.
- Advise patient *not* to swallow drug in dry form.
- Counsel patient to avoid overuse of laxatives, which can lead to fluid and electrolyte imbalances and drug dependence. Suggest exercise to help increase peristalsis.
- Advise patient to avoid inhaling psyllium dust; it may cause watery eyes, runny nose, and wheezing.

Side Effects

- Encourage patient to discontinue use if nausea, vomiting, cramping, or rectal bleeding occurs.

Diet

- Instruct patient to mix drug in 8 to 10 oz of water, stir, and drink immediately. At least one glass of extra water should follow. Insufficient water can cause drug to solidify and lead to dry, hard stools, and fecal impaction.
- Encourage patient to increase foods rich in fiber (bran, grains, vegetables, fruits).
- Inform patient to increase water intake (at least 8 oz of fluids per day), which will decrease hard, dry stools.

Cultural Considerations

- Respect patient's cultural beliefs and alternative methods for treating constipation. Suggest nonpharmacologic methods that might be of benefit.
- Provide additional explanation about use and abuse of laxatives, and provide written materials in a language that patient speaks and reads most easily.

Evaluation

- Determine effectiveness of nonpharmacologic methods for alleviating constipation.
- Evaluate patient's use of laxatives in managing constipation.
- Identify laxative abuse.

KEY WEBSITES

Activated charcoal: *www.mayoclinic.com/health/drug-information/DR602267*

Promethazine: *www.nlm.nih.gov/medlineplus/druginfo/meds/a682284.html*

CRITICAL THINKING CASE STUDY

CS, a 34-year-old woman, has been vomiting for 48 hours. In the last 12 hours, CS has had vomiting and diarrhea. Prochlorperazine (Compazine) 10 mg was administered intramuscularly.

1. What nonpharmacologic measures should the nurse suggest when vomiting occurs?
2. Why was CS given prochlorperazine intramuscularly and not orally or rectally? Prochlorperazine should be given deep intramuscularly. Why?
3. What electrolyte imbalances may occur as a result of vomiting and diarrhea? Explain how they can be replaced.
4. What are the side effects of prochlorperazine? Could these occur to CS? Explain your answer.
5. Could a serotonin antagonist be given to CS instead of prochlorperazine? Explain your answer.

   CS was prescribed diphenoxylate with atropine (Lomotil) 2.5 mg t.i.d.
6. Is the diphenoxylate with atropine (Lomotil) dosage for CS within the normal prescribed range? Explain your answer.
7. What clinical conditions are contraindicated for the use of Lomotil?
8. What are some combination drugs that may be prescribed to control diarrhea? Give their advantages and disadvantages.
9. Explain the similarities of two over-the-counter antidiarrheals. Explain how frequently they should be administered.
10. Do you think CS should receive an adsorbent? Explain your answer.
11. Explain the similarities and differences between ipecac and charcoal.

NCLEX STUDY QUESTIONS

1. A patient complains of constipation and requires a laxative. In providing teaching for this patient, the nurse reviews the common causes of constipation, including which cause?
   a. Motion sickness
   b. Poor dietary habits
   c. Food intolerance
   d. Bacteria *(Escherichia coli)*
2. A patient with nausea is taking ondansetron (Zofran). She asks the nurse how this drug works. The nurse is aware that this medication has which action?
   a. Enhances histamine$_1$ receptor sites
   b. Blocks serotonin receptors in the CTZ
   c. Blocks dopamine receptors in the CTZ
   d. Stimulates anticholinergic receptor sites
3. A patient who has constipation is prescribed a bisacodyl (Dulcolax) suppository. Which explanation will the nurse use to explain the action of bisacodyl?
   a. Acts on smooth intestinal muscle to gently increase peristalsis
   b. Absorbs water into the intestines to increase bulk and peristalsis
   c. Lowers surface tension and increases water accumulation in the intestines
   d. Pulls salts into the colon and increases water in the feces to increase bulk
4. A patient is using scopolamine (Transderm-Scōp) to prevent motion sickness. About which common side effect should the nurse teach the patient?
   a. Diarrhea
   b. Vomiting
   c. Insomnia
   d. Dry mouth
5. When metoclopramide (Reglan) is given for nausea, the nurse plans to caution the patient to avoid which substance?
   a. Milk
   b. Coffee
   c. Alcohol
   d. Carbonated beverages
6. The nurse is administering diphenoxylate with atropine (Lomotil) to a patient. Which should be included in the patient teaching regarding this medication? (Select all that apply.)
   a. Caution the patient to avoid laxative abuse.
   b. Record the frequency of bowel movements.
   c. Caution the patient against taking sedatives concurrently.
   d. Encourage the patient to increase fluids.
   e. Instruct the patient to avoid this drug if he or she has narrow-angle glaucoma.
   f. Teach the patient that the drug acts by drawing water into the intestine.

Answers: 1, b; 2, b; 3, a; 4, d; 5, c; 6, a, b, c, d, e.

CHAPTER 48

Antiulcer Drugs

evolve WEBSITE

- Key Points
- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Explain the predisposing factors for peptic ulcers.
- Differentiate between peptic ulcer, gastric ulcer, duodenal ulcer, and gastroesophageal reflux disease.
- Compare the actions of seven groups of antiulcer drugs used in the treatment of peptic ulcer: tranquilizers, anticholinergics, antacids, histamine$_2$ blockers, proton pump inhibitors, pepsin inhibitor, and prostaglandin analogue.
- Plan patient teaching for the following drug groups: anticholinergics, antacids, and histamine$_2$ blockers.
- Differentiate between the side effects of anticholinergics and systemic and nonsystemic antacids.
- Apply the nursing process, including teaching, to antiulcer drugs.

OUTLINE

Predisposing Factors in Peptic Ulcer Disease

histamine$_2$ receptor antagonists, p. 698
hydrochloric acid, p. 693
pepsin, p. 694
peptic ulcer, p. 693
stress ulcer, p. 694

Peptic ulcer is a broad term for an ulcer occurring in the esophagus, stomach, or duodenum within the upper gastrointestinal (GI) tract. Ulcers are more specifically named according to the site of involvement: esophageal, gastric, and duodenal ulcers. Duodenal ulcers occur 10 times more frequently than gastric and esophageal ulcers. The release of **hydrochloric acid** (HCl) from the parietal cells of the stomach is influenced by histamine, gastrin, and acetylcholine. Peptic ulcers occur when there is a hypersecretion of hydrochloric acid and pepsin, which erode the GI mucosal lining.

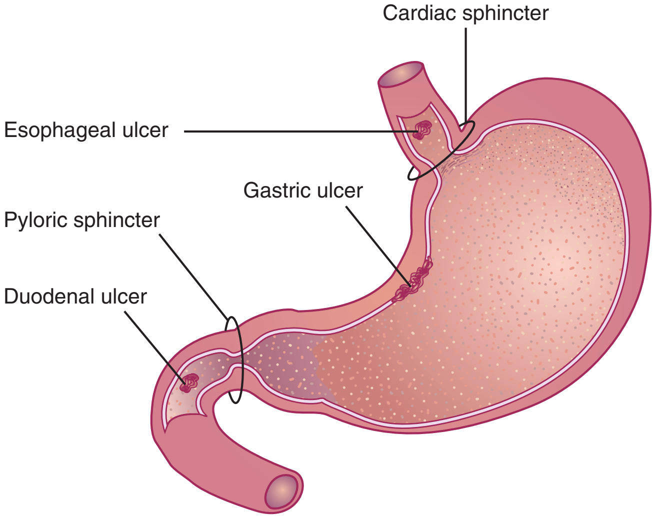

FIGURE 48–1 Common sites of peptic ulcers.

The gastric secretions in the stomach strive to maintain a pH of 2 to 5. **Pepsin,** a digestive enzyme, is activated at a pH of 2, and the acid-pepsin complex of gastric secretions can cause mucosal damage. If the pH of gastric secretions increases to pH 5, the activity of pepsin declines. The **gastric mucosal barrier** (**GMB**) is a thick, viscous, mucous material that provides a barrier between the mucosal lining and acidic gastric secretions. The GMB maintains the integrity of the gastric mucosal lining and is a defense against corrosive substances. The two sphincter muscles—the *cardiac,* located at the upper portion of the stomach, and the *pyloric,* located at the lower portion of the stomach—act as barriers to prevent reflux of acid into the esophagus and duodenum. Figure 48-1 shows common sites of peptic ulcers.

An **esophageal ulcer** results from reflux of acidic gastric secretions into the esophagus as a result of a defective or incompetent cardiac sphincter. A **gastric ulcer** frequently occurs because of a breakdown of the GMB. A **duodenal ulcer** is caused by hypersecretion of acid from the stomach passing into the duodenum because of (1) insufficient buffers to neutralize gastric acid in the stomach, (2) a defective or incompetent pyloric sphincter, or (3) hypermotility of the stomach. **Gastroesophageal reflux disease** (**GERD**) is inflammation or erosion of the esophageal mucosa caused by a reflux of gastric acid content from the stomach into the esophagus.

PREDISPOSING FACTORS IN PEPTIC ULCER DISEASE

The nurse needs to assist the patient in identifying possible causes of the ulcer and to teach ways to alleviate them. Predisposing factors include mechanical disturbances, genetic influences, bacterial organisms, environmental factors, and certain drugs. Healing of an ulcer takes 4 to 8 weeks. Complications can occur as the result of scar tissue. Table 48-1 lists the predisposing factors for peptic ulcers and their effects.

TABLE 48-1 PREDISPOSING FACTORS FOR PEPTIC ULCER DISEASE

PREDISPOSING FACTORS	EFFECTS
Mechanical disturbances	Hypersecretion of acid and pepsin. Inadequate GMB mucous secretion. Impaired GMB resistance. Hypermotility of the stomach. Incompetent (defective) cardiac or pyloric sphincter.
Genetic influences	Increased number of parietal cells in the stomach. Susceptibility of mucosal lining to acid penetration. Susceptibility to excess acetylcholine and histamine. Excess hydrochloric acid caused by external stimuli.
Environmental influences	Foods and liquids containing caffeine; fatty, fried, and highly spiced foods; alcohol. Nicotine, especially from cigarette smoking. Stressful situations. Pregnancy, massive trauma, major surgery.
Helicobacter pylori	A gram-negative bacterium, *H. pylori,* infects gastric mucosa and can cause gastritis, gastric ulcer, and duodenal ulcer. If not eradicated, peptic ulcer may return as frequently as every year. *H. pylori* can lead to atrophic gastritis in some patients. Serology and special breath tests can detect the presence of *H. pylori.*
Drugs	NSAIDs, including aspirin and aspirin compounds, ibuprofen (Motrin, Advil, Nuprin), and indomethacin (Indocin); corticosteroids (cortisone, prednisone); potassium salts; antineoplastic drugs.

GMB, Gastric mucosal barrier; *NSAIDs,* nonsteroidal antiinflammatory drugs.

The classic symptom of peptic ulcers is gnawing, aching pain. With a gastric ulcer, pain occurs 30 minutes to 1.5 hours after eating, and with a duodenal ulcer, 2 to 3 hours after eating. Small, frequent meals of nonirritating foods decrease the pain. With treatment, pain usually subsides in 10 days; however, the healing process may take 1 to 2 months.

A **stress ulcer** usually follows a critical situation such as extensive trauma or major surgery (e.g., burns, cardiac surgery). Prophylactic use of antiulcer drugs decreases the incidence of stress ulcers.

Helicobacter pylori

Helicobacter pylori, a gram-negative bacillus, is linked with the development of peptic ulcer and is known to cause gastritis, gastric ulcer, and duodenal ulcer. When a peptic ulcer recurs after antiulcer therapy, and the ulcer is not caused by nonsteroidal antiinflammatory drugs (NSAIDs) such as aspirin or ibuprofen, the patient should be tested for the presence of the bacterium *H. pylori,* which may have infected the gastric mucosa. In the past, endoscopy and a biopsy of the gastric antrum were needed to check for *H. pylori.* Currently a noninvasive breath test, the Meretek UBT, can detect *H. pylori.* This test consists of drinking a liquid containing 13C urea and breathing into a container. If *H. pylori* is present, the bacterial urease hydrolyzes the urea, releasing $13CO_2$, which is detected by a spectrometer. This test is 90% to 95% effective for detecting *H. pylori.* In addition, a serology test may be performed to check for antibodies to *H. pylori.*

There are various protocols for treating *H. pylori* infection, but antibacterial agents are the treatment of choice. The use of only one antibacterial agent is not effective for eradicating *H. pylori,* because the bacterium can readily become resistant to that drug. Treatment to eradicate this bacterial infection includes using a dual-, triple-, or quadruple drug therapy program in a variety of drug combinations, such as amoxicillin (Amoxil), tetracycline (Achromycin V), clarithromycin (Biaxin), omeprazole (Prilosec), lansoprazole (Prevacid), metronidazole (Flagyl), bismuth subsalicylate (Pepto-Bismol), and ranitidine bismuth citrate (Tritec), on a 7- to 14-day treatment plan. The combination of drugs differs for each patient according to the patient's drug tolerance. A common treatment protocol is the triple therapy of metronidazole (or amoxicillin), omeprazole (or lansoprazole), and clarithromycin (MOC). The drug regimen eradicates more than 90% of peptic ulcer caused by *H. pylori* (Herbal Alert 48-1).

HERBAL ALERT 48-1

Herbs and Tetracycline

St. John's wort may increase the risk for photosensitivity when taken with tetracycline.

One of the proton pump inhibitors (PPIs) (e.g., omeprazole, lansoprazole) is frequently used as a component of combination drug therapy, because each suppresses acid secretion by inhibiting the enzyme hydrogen or potassium ATPase, which makes gastric acid. These agents block the final steps of acid production. If triple therapy fails to eradicate *H. pylori,* then quadruple therapy using two antibiotics, a PPI, and a bismuth or histamine$_2$ (H_2) blocker is recommended. After completion of the treatment regimen, 6 weeks of standard acid suppression, such as H_2 blocker therapy, is recommended. Table 48-2 lists agents used to treat *H. pylori* with their dosages, uses, and considerations.

Gastroesophageal Reflux Disease

Gastroesophageal reflux disease (GERD), also called *reflux esophagitis,* is an inflammation of the esophageal mucosa caused by reflux of gastric acid content into the esophagus. Its main cause is an incompetent lower esophageal sphincter. Smoking tends to accelerate the disease process.

Medical treatment for GERD is similar to the treatment for peptic ulcers. This includes use of the common antiulcer drugs to neutralize gastric contents and reduce gastric acid secretion. Drugs used in treatment include H_2 blockers such as ranitidine (Zantac), and PPIs such as omeprazole (Prilosec), lansoprazole (Prevacid), rabeprazole (Aciphex), pantoprazole (Protonix), or esomeprazole (Nexium). A PPI relieves symptoms faster and maintains healing better than an H_2 blocker. Once the strictures are relieved by dilation, they are less likely to recur if the patient was taking PPIs rather than an H_2 blocker.

Effective management of GERD keeps the esophageal mucosa healed and the patient free from symptoms, but GERD is a chronic disorder that requires continuous care.

TABLE 48-2 PHARMACOLOGIC AGENTS USED TO TREAT *HELICOBACTER PYLORI*

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Antiinfective Agents		
metronidazole HCl (Flagyl)	A: PO: 250 q.i.d.	To treat numerous organisms, including *H. pylori.* Used in combination with other drugs to treat *H. pylori.*
amoxicillin (Amoxil)	A: PO: 1000 mg b.i.d	Used in triple or quadruple therapy for *H. pylori*
clarithromycin (Biaxin)	A: PO: 500 mg b.i.d.	Used in dual and triple therapy for *H. pylori*
tetracycline (Sumycin)	A: PO: 500 mg q.i.d.	Used in triple and quadruple therapy for *H. pylori*
Proton Pump Inhibitors (PPIs)		
omeprazole (Prilosec)	A: PO: 20 mg/b.i.d. or 40 mg/d	Used in dual, triple, and quadruple therapy for *H. pylori*
lansoprazole (Prevacid)	A: PO: 30 mg b.i.d.	Used in dual and triple therapy for *H. pylori*
esomeprazole (Nexium)	A: PO: 40 mg/d	Used in therapy for *H. pylori*
pantoprazole (Protonix)	A: PO: 40 mg/d	Used in therapy for *H. pylori*
rabeprazole (Aciphex)	A: PO: 20 mg b.i.d.	Used in therapy for *H. pylori*
Antacids		
bismuth subsalicylate	A: PO: 525 mg q.i.d. (or 2 tabs q.i.d.)	Used in combination with other drugs to treat *H. pylori*
bismuth subcitrate potassium	A: PO: 420 mg (or 3 caps) q.i.d.	Used in combination with other drugs to treat *H. pylori*

A, Adult; *b.i.d.,* twice a day; *d,* day; *PO,* by mouth; *q.i.d.,* four times a day; *t.i.d.,* three times a day; *tab,* tablet.

NONPHARMACOLOGIC MEASURES FOR MANAGING PEPTIC ULCER AND GASTROESOPHAGEAL REFLUX DISEASE

Nonpharmacologic measures, along with drug therapy, are an important part of treatment for a GI disorder. Once the GI problem is resolved, the patient should continue to follow nonpharmacologic measures to avoid recurrence of the condition.

Avoiding tobacco and alcohol can decrease gastric secretions. With GERD, nicotine relaxes the lower esophageal sphincter, permitting gastric acid reflux. Obesity enhances GERD; weight loss is helpful in decreasing symptoms. The patient should avoid hot, spicy, and greasy foods, which could aggravate the gastric problem. Certain drugs like NSAIDs, which include aspirin, should be taken with food or in a decreased dosage. Glucocorticoids can cause gastric ulceration and should be taken with food.

To relieve symptoms of GERD, the patient should raise the head of the bed, not eat before bedtime, and wear loose-fitting clothing.

SAFETY: Preventing Medication Errors

Do not confuse …

- **ranitidine** (H_2 blocker) with **rimantadine** (an antiviral) or **amantadine** (an antiviral and antiparkinsonism agent)
- **Zantac** (H_2 blocker) with **Xanax** (anxiolytic)

ANTIULCER DRUGS

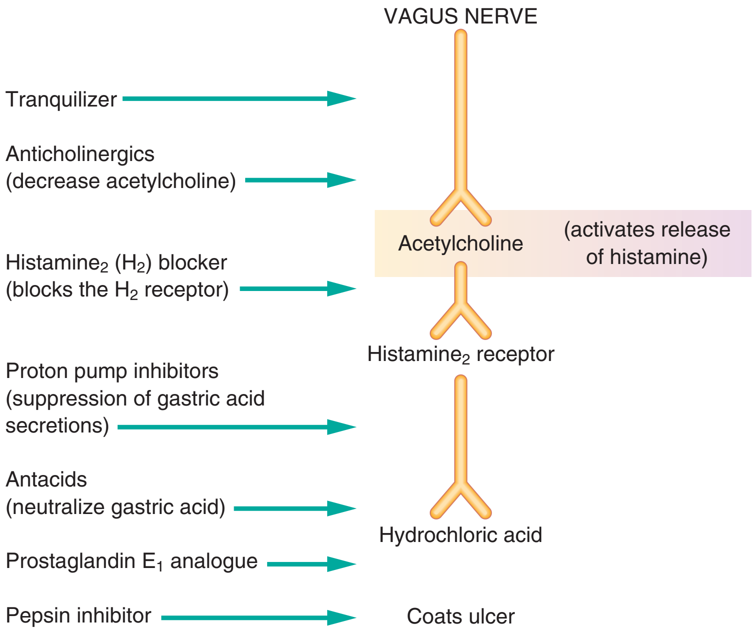
There are seven groups of antiulcer agents: (1) tranquilizers, which decrease vagal activity; (2) anticholinergics, which decrease acetylcholine by blocking the cholinergic receptors; (3) antacids, which neutralize gastric acid; (4) H_2 blockers, which block the H_2 receptor; (5) PPIs, which inhibit gastric acid secretion, regardless of acetylcholine or histamine release; (6) the pepsin inhibitor sucralfate; and (7) the prostaglandin E_1 analogue misoprostol, which inhibits gastric acid secretion and protects the mucosa. Currently, tranquilizers and anticholinergics are used infrequently due to potential adverse effects and much more effective drugs on the market. Figure 48-2 shows the action of the antiulcer drug groups, each of which is discussed separately.

Tranquilizers

Tranquilizers have minimal effect in preventing and treating ulcers; however, they reduce vagal stimulation and decrease anxiety. Generic versions of Librax, a reformulated product of the anxiolytic chlordiazepoxide (Librium) and the anticholinergic clidinium bromide (Quarzan), may be used in the treatment of ulcers. Adverse effects may include edema, ataxia, confusion, extrapyramidal syndrome (EPS), and agranulocytosis.

Anticholinergics

Anticholinergics (antimuscarinics, parasympatholytics) and antacids were the drugs of choice for peptic ulcers for many



VAGUS NERVE
Tranquilizer
Anticholinergics (decrease acetylcholine)
Acetylcholine
(activates release of histamine)
Histamine$_2$ (H$_2$) blocker (blocks the H$_2$ receptor)
Histamine$_2$ receptor
Proton pump inhibitors (suppression of gastric acid secretions)
Antacids (neutralize gastric acid)
Hydrochloric acid
Prostaglandin E$_1$ analogue
Pepsin inhibitor
Coats ulcer

FIGURE 48–2 Actions of the antiulcer drug groups.

TABLE 48-3 ANTIULCER DRUGS: ANTICHOLINERGICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
clidinium bromide and chlordiazepoxide HCl	A: PO: 1-2 cap t.i.d./q.i.d. a.c./h.s.	Decreases anxiety and GI distress. Contains a benzodiazepine. Pregnancy category: D; PB: UK; t½: 5-100 h
glycopyrrolate (Robinul)	A/C: >12 y: PO: 1-2 mg b.i.d./t.i.d.; *max:* 6 mg/d IM/IV: 0.1-0.2 mg t.i.d./q.i.d.	For peptic ulcers and gastric disorders caused by hyperacidity. Used as a preanesthetic drug. Same contraindications as belladonna. Pregnancy category: B; PB: UK; t½: UK
propantheline bromine (Pro-Banthine)	A: PO: 15 mg t.i.d. 30 min a.c. and 30 mg h.s.; *max:* 120 mg/d Older adults: PO: 7.5 mg b.i.d./t.i.d. a.c.; *max:* 90 mg/d	For peptic ulcers; decreases gastric secretions, irritable bowel syndrome, pancreatitis, and urinary bladder spasm. Standard anticholinergic side effects. Pregnancy category: C; PB: UK; t½: 1.6 h

A, Adult; *a.c.,* before meals; *b.i.d.,* twice a day; *C,* child; *cap,* capsule; *d,* day; *GI,* gastrointestinal; *h,* hour; *h.s.,* at bedtime; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown.

years. However, anticholinergic use has declined with the introduction of H_2 blockers in 1975. These drugs relieve pain by decreasing GI motility and secretion. They act by inhibiting acetylcholine and blocking histamine and hydrochloric acid. Anticholinergics delay gastric emptying time, so they are used more frequently for duodenal ulcers than for gastric ulcers. The anticholinergic propantheline bromine (Pro-Banthine) inhibits gastric secretions in the treatment of peptic ulcers.

Anticholinergics should be taken before meals to decrease the acid secretion that occurs with eating. Antacids can slow the absorption of anticholinergics and therefore should be taken 2 hours after anticholinergic administration.

Table 48-3 lists selected the anticholinergic drugs used to treat peptic ulcer. Anticholinergics should be used as adjunctive therapy and not as the only antiulcer drug. Anticholinergics are discussed in more detail in Chapter 19.

Side Effects and Adverse Reactions

Anticholinergics have many side effects, including dry mouth, decreased secretions, headache, blurred vision, drowsiness, dizziness, lethargy, palpitations, bradycardia, tachycardia, urinary retention, and constipation. Because anticholinergics decrease GI motility, gastric emptying time is delayed, which can stimulate gastric secretions and aggravate the ulceration.

Antacids

Antacids promote ulcer healing by neutralizing hydrochloric acid and reducing pepsin activity; they do not coat the ulcer. There are two types of antacids: those that have a *systemic* effect and those that have a *nonsystemic* effect.

Sodium bicarbonate, a systemically absorbed antacid, was one of the first antiulcer drugs. Because it has many side effects (sodium excess, causing hypernatremia and water retention; metabolic alkalosis caused by excess bicarbonate; and acid rebound [excess acid secretion]), sodium bicarbonate is seldom used to treat peptic ulcers. An example of a sodium bicarbonate compound is Alka-Seltzer.

Calcium carbonate is most effective in neutralizing acid; however, one third to one half of the drug can be systemically absorbed and can cause acid rebound. Hypercalcemia and Burnett's syndrome, formerly called *milk-alkali syndrome*, can result from excessive use of calcium carbonate. Burnett's syndrome is intensified if milk products are ingested with calcium carbonate. It is identified by the presence of alkalosis, hypercalcemia, and in severe cases crystalluria and renal failure.

The nonsystemic antacids are composed of alkaline salts such as aluminum (aluminum hydroxide) and magnesium (magnesium hydroxide, magnesium trisilicate). There is a small degree of systemic absorption with these drugs, mainly of aluminum. Magnesium hydroxide has greater neutralizing power than aluminum hydroxide. Magnesium compounds can cause diarrhea, and aluminum and calcium compounds can cause constipation with long-term use. A combination of magnesium and aluminum salts neutralizes gastric acid without causing severe diarrhea or constipation. Simethicone (an antigas agent) is found in many antacids, including Mylanta Gas, Maalox Antigas, and Mylicon. Prototype Drug Chart 48-1 lists the pharmacologic data for aluminum hydroxide antacids.

Pharmacokinetics Aluminum hydroxide (Amphojel) was one of the first antacids used to neutralize hydrochloric acid. Aluminum products are frequently used to lower high serum phosphate (hyperphosphatemia). Because aluminum hydroxide alone can cause constipation, and magnesium products alone can cause diarrhea, combination drugs such as aluminum hydroxide and magnesium hydroxide (Maalox Caplet) have become popular, because they decrease these side effects.

Only a small amount of aluminum hydroxide is absorbed from the GI tract. It is primarily bound to phosphate and excreted in the feces. The small portion that is absorbed is excreted in the urine.

Pharmacodynamics Aluminum hydroxide neutralizes gastric acid, including hydrochloric acid, and increases the pH of gastric secretions (an elevated pH inactivates pepsin). The onset of action is fairly rapid, but the duration of action varies, depending on whether the antacid is taken with or without food. If the antacid is taken after a meal, the duration of action may be up to 3 hours, because food delays gastric emptying time. Frequent dosing may be necessary if the antacid is given during a fasting state or early in the course of treatment.

PROTOTYPE DRUG CHART 48-1

Aluminum Hydroxide

Drug Class Antiulcer: antacid Trade Name: Amphojel Pregnancy Category: C	**Dosage** Antacid: A: PO: susp: 5-15 mL 1 h p.c. and h.s. Hyperphosphatemia: A: PO: 10-30 mL (suspension) t.i.d./q.i.d. with meals
Contraindications Hypersensitivity to aluminum products, hypophosphatemia Caution: In older adults	**Drug-Lab-Food Interactions** Drug: Decrease effects with tetracycline, phenothiazine, isoniazid, phenytoin, digitalis, quinidine, amphetamines. May increase effect of benzodiazepines Lab: Increase urine pH
Pharmacokinetics Absorption: PO: Small amount absorbed Distribution: PB: UK Metabolism: $t\frac{1}{2}$: UK Excretion: In feces; small amount in urine	**Pharmacodynamics** PO: Onset: 15-30 min Peak: 0.5 h Duration: 1-3 h
Therapeutic Effects/Uses To treat hyperacidity, peptic ulcer, and reflux esophagitis; to reduce hyperphosphatemia Mode of Action: Neutralizes gastric acidity	
Side Effects Anorexia, constipation	**Adverse Reactions** Hypophosphatemia, osteoporosis, nephrolithiasis; long-term use can result in GI obstruction

A, Adult; *cap,* capsule; *GI,* gastrointestinal; *h,* hour; *h.s.,* at bedtime; *min,* minute; *PB,* protein-binding; *p.c.,* after meals; *PO,* by mouth; *q.i.d.,* four times a day; *susp,* suspension; $t\frac{1}{2}$, half-life; *t.i.d.,* three times a day; *UK,* unknown.

The ideal dosing interval for antacids is 1 and 3 hours after meals (maximum acid secretion occurs after eating) and at bedtime. Antacids taken on an empty stomach are effective for 30 to 60 minutes before passing into the duodenum. Chewable tablets should be followed by water. Liquid antacids should also be taken with water (2 to 4 ounces) to ensure that the drug reaches the stomach; however, no more than 4 ounces of water should be taken, because water quickens gastric emptying time.

Antacids containing magnesium salts are contraindicated in patients with impaired renal function because of the risk for hypermagnesemia. Magnesium is primarily excreted by the kidneys; however, hypermagnesemia is usually not a problem unless a patient with renal insufficiency is ingesting magnesium. Prolonged use of aluminum hydroxides can cause hypophosphatemia (low serum phosphate), osteoporosis, nephrolithiasis, and osteomalacia. If hyperphosphatemia occurs because of poor renal function, aluminum hydroxide can be given to decrease the phosphate level. In patients with renal insufficiency, aluminum salt ingestion can cause encephalopathy from accumulation of aluminum in the brain. Table 48-4 lists the antacids and their dosages, uses, and considerations.

Histamine$_2$ Blockers

The histamine$_2$ (H_2) blockers (**histamine$_2$ receptor antagonists**) are popular drugs used in the treatment of gastric and duodenal ulcers. Histamine$_2$ blockers prevent acid reflux in the esophagus (reflux esophagitis). These drugs block the H_2 receptors of the parietal cells in the stomach, thus reducing gastric acid secretion and concentration. Antihistamines, used to treat allergic conditions, act against histamine$_1$ (H_1); they are not the same as H_2 blockers.

The first H_2 blocker was cimetidine (Tagamet), introduced in 1975. Cimetidine, which has a short half-life and a short duration of action, blocks about 70% of acid secretion for 4 hours. Good kidney function is necessary, because approximately 50% to 80% of the drug is excreted unchanged in the urine. In patients with renal insufficiency, the dose and frequency may need to be reduced. Antacids can be given 1 hour before or after cimetidine as part of an antiulcer drug regimen; however, if they are given at the same time, the effectiveness of the H_2 blocker is decreased.

Nursing Process

Patient-Centered Collaborative Care

Antiulcer: Antacids

Assessment

- Evaluate patient's pain, including type, duration, severity, and frequency.
- Check patient's renal function.
- Assess for fluid and electrolyte imbalances, especially serum phosphate and calcium levels.

TABLE 48-4 ANTIULCER DRUGS: ANTACIDS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
aluminum hydroxide (Amphojel, AlternaGEL)	See Prototype Drug Chart 48-1.	
calcium carbonate (Tums)	A: PO: 0.5-2 g b.i.d./t.i.d.	To alleviate heartburn, acid indigestion, esophagitis, and hiatal hernia caused by hyperacidity. Also used to treat hyperphosphatemia in patients with renal disorders. OTC drug. One third of drug dose absorbed from GI tract. Constipation can be a problem. Pregnancy category: C; PB: 40%; t½: UK
magaldrate (Riopan)	A: PO: 5-10 mL PRN or 1-2 tab PRN; *max:* 100 mL/d or 20 tab/d	To alleviate heartburn, gastritis, esophagitis, and peptic ulcers caused by hyperacidity. Contains aluminum and magnesium hydroxide. Low sodium content. Simethicone decreases flatus. Drug is minimally absorbed. Pregnancy category: B; PB: UK; t½: UK
calcium carbonate and magnesium hydroxide (Rolaids, Mylanta, Tums)	A: PO: Chew 2-4 tabs between meals and h.s.	For heartburn, dyspepsia, and flatulence. Pregnancy category: C; PB: UK; t½: UK
magnesium hydroxide and aluminum hydroxide (Maalox Caplet, Mylanta Ultimate Strength)	A: PO: 2-4 tab PRN; *max:* 16 tab/d or 10-30 mL, 1-3 h p.c. and h.s.	Same as magaldrate. Caution for patients with renal disorder caused by magnesium content. OTC drug. Pregnancy category: B; PB: UK; t½: UK
magnesium hydroxide and aluminum hydroxide with simethicone (Mylanta, Maalox, Gelusil)	A: PO: 10-20 mL PRN; *max:* 120 mL/d; or 2-4 tab PRN; *max:* 24 tab/d	Same as magaldrate. Also contains simethicone, which decreases flatus. OTC drug. Pregnancy category: B; PB: UK; t½: UK
magnesium trisilicate with aluminum hydroxide (Gaviscon Regular Strength)	A: PO: 2-4 tab q.i.d.; *max:* 16 tab/d	To relieve gastric disorders caused by hyperacidity. OTC drug. Contains magnesium trisilicate and aluminum hydroxide. Pregnancy category: UK; PB: UK; t½: UK
sodium bicarbonate (Alka-Seltzer Heartburn Relief)	A: PO: 300 mg-2 g 1-4 times/d	Previously used for gastric hyperacidity. Short-acting, potent antacid that is systemically absorbed. Acid-base imbalance could occur. Pregnancy category: C; PB: UK; t½: UK

A, Adult; *cap,* capsule; *d,* day; *GI,* gastrointestinal; *h,* hour; *h.s.,* at bedtime; *max,* maximum; *OTC,* over-the-counter; *PB,* protein-binding; *p.c.,* after meals; *PO,* by mouth; *PRN,* as needed; *t½,* half-life; *tab,* tablet; *tsp,* teaspoon; *UK,* unknown.

- Obtain drug history; report probable drug-drug interactions.

Nursing Diagnoses

- Acute pain related to repeated spicy food and alcohol ingestion
- Ineffective health maintenance related to misuse of antacids
- Deficient knowledge related to misinterpretation of information

Planning

- Patient's abdominal pain will decrease after 1 to 2 weeks of antiulcer drug management.

Nursing Interventions

- Avoid administering antacids with other oral drugs, because antacids can delay their absorption. Do not give an antacid with tetracycline, digoxin, or quinidine, because it binds with and inactivates most of the drug. Antacids are given 1 to 2 hours after other medications.
- Shake suspension well before administering; follow with water.
- Monitor electrolytes and urinary pH, calcium, and phosphate levels.

Patient Teaching

General

- Teach patient to report pain, coughing, or vomiting of blood.
- Encourage patient to drink 2 oz of water after antacid to ensure that drug reaches stomach.
- Direct patient to take antacid 1 to 3 hours after meals and at bedtime. Instruct patient not to take antacids at mealtime; they slow gastric emptying time, causing increased GI activity and gastric secretions.
- Advise patient to notify health care provider if constipation or diarrhea occurs; the antacid may have to be changed. Self-treatment should be avoided.
- Warn that taking an unlimited amount of the antacid is contraindicated.
- Warn patient to avoid taking antacids with milk or foods high in vitamin D.
- Advise patient to avoid taking antacids within 1 to 2 hours of other oral medications, because they may interfere with absorption.

- Guide patient on a sodium-restricted diet to check antacid labels for sodium content.
- Alert patient to consult with health care provider before taking self-prescribed antacids for longer than 2 weeks.
- Inform patient on use of relaxation techniques.

Self-Administration

- Teach patient how to take antacids correctly. Chewable tablets must be thoroughly chewed and followed with water. With liquid antacid, patient should follow antacid with 2 to 4 ounces of water. Increased amount of water with antacids increases gastric emptying time.

Side Effects

- Direct patient to avoid food and beverages that can cause gastric irritation (high-fat or spicy meals; caffeine-containing coffee and soda; alcohol).
- Explain to patient that stools may become speckled or white.

Cultural Considerations

- Respect patient's cultural beliefs and alternative methods for treating GI discomfort.
- Discuss with patient the safety of those methods and the use of drugs prescribed to heal and lessen the symptoms.
- Recognize that patients of various cultural backgrounds may need guidance in understanding the disease process of their GI disturbance. Use of a written plan of care with modifications should be considered.

Evaluation

- Determine the effectiveness of the antiulcer treatment and the presence of side effects. Patient should be free of pain, and healing should progress.

Three H_2 blockers, ranitidine (Zantac), famotidine (Pepcid), and nizatidine (Axid), are more potent than cimetidine. In addition to blocking gastric acid secretions, they promote healing of the ulcer by eliminating its cause. Their duration of action is longer, decreasing the frequency of dosing, and they have fewer side effects and fewer drug interactions than cimetidine. Prototype Drug Chart 48-2 lists the pharmacologic data for ranitidine (Zantac), the most frequently prescribed H_2 blocker.

Pharmacokinetics Ranitidine is 5 to 12 times more potent than cimetidine but less potent than famotidine. It is rapidly absorbed and reaches its peak concentration after a single dose in 1 to 3 hours. Ranitidine has a low protein-binding power and a short half-life. With liver disease, the half-life of ranitidine is prolonged. About 50% of the absorbed drug is excreted unchanged in the urine.

Ulcer healing occurs in 4 weeks for 70% of patients and in 8 weeks for 90% of patients taking ranitidine. Large doses of ranitidine are effective for controlling Zollinger-Ellison syndrome, whereas cimetidine is not effective in controlling the symptoms of this disorder.

Pharmacodynamics Ranitidine inhibits histamine at the H_2 receptor site. The drug is effective in treating gastric and duodenal ulcers and can be used prophylactically. It is also useful in relieving symptoms of reflux esophagitis, preventing stress ulcers that can occur following major surgery, and preventing aspiration pneumonitis that can result from aspiration of gastric acid secretions.

Ranitidine has a longer onset of action and duration of action (up to 12 hours) than cimetidine. Because the duration of action of cimetidine is only 4 to 5 hours, it is frequently given three to four times a day.

Famotidine (Pepcid) is 50% to 80% more potent than cimetidine and is five to eight times more potent than ranitidine. It is indicated for short-term use (4 to 8 weeks) for duodenal ulcer and for Zollinger-Ellison syndrome.

Nizatidine (Axid) is an H_2 blocker that can relieve nocturnal gastric acid secretion for 12 hours. This drug is similar to famotidine and ranitidine, and none of these agents suppresses the metabolism of other drugs. To prevent recurrence of duodenal ulcers, administer nizatidine 150 mg/day at bedtime or famotidine 20 mg/day at bedtime. Both nizatidine and famotidine have similar protein-binding times and half-lives.

Table 48-5 lists the H_2 blockers and their dosages, uses, and considerations.

Side Effects and Adverse Reactions. Side effects and adverse reactions of H_2 blockers include headache, dizziness, constipation, pruritus, skin rash, gynecomastia, decreased libido, and impotence. Ranitidine and famotidine have fewer side effects than cimetidine.

Drug and Laboratory Interactions. Cimetidine interacts with many drugs. By inhibiting hepatic drug metabolism, it enhances the effects of oral anticoagulants, theophylline, caffeine, phenytoin (Dilantin), diazepam (Valium), propranolol (Inderal), phenobarbital, and calcium channel blockers. Cimetidine can cause an increase in blood urea nitrogen (BUN), serum creatinine, and serum alkaline phosphatase. Neither cimetidine nor ranitidine should be taken with antacids, because their H_2 blocking action could be decreased. Ranitidine can increase the effect of oral anticoagulants. Table 48-5 lists the H_2 blockers and their dosages, uses, and considerations.

Nursing Process
Patient-Centered Collaborative Care

Antiulcer: Histamine$_2$ Blocker

Assessment

- Determine patient's pain, including type, duration, severity, frequency, and location.
- Evaluate GI complaints.
- Check mental status.
- Assess fluid and electrolyte imbalances, including intake and output.

PROTOTYPE DRUG CHART 48-2

Ranitidine

Drug Class

Antiulcer: histamine$_2$ blocker
Trade Name: Zantac
Pregnancy Category: B

Dosage

A: PO: 150 mg q12h or 300 mg h.s.; maint: 150 mg h.s.
A: IM: 50 mg q6-8h
A: IV: 50 mg q6-8h diluted
C: PO: 2-4 mg/kg/d divided q12h
C: IV: 1-2 mg/kg/d divided q6-8h

Contraindications

Hypersensitivity, severe renal or liver disease
Caution: Pregnancy, lactation

Drug-Lab-Food Interactions

Drug: Decrease absorption with antacids; decrease absorption of ketoconazole; toxicity with metoprolol
Lab: Increase serum alkaline phosphatase

Pharmacokinetics

Absorption: PO: well absorbed, 50%
Distribution: PB: 15%
Metabolism: t½: 2-3 h
Excretion: In urine and feces

Pharmacodynamics

PO: Onset: 15 min
Peak: 1-3 h
Duration: 8-12 h
IM/IV: Onset: 10-15 min
Peak: 15 min
Duration: 8-12 h

Therapeutic Effects/Uses

To prevent and treat peptic ulcers, gastroesophageal reflux, and stress ulcers
Mode of Action: Inhibits gastric acid secretion by inhibiting histamine at histamine$_2$ receptors in parietal cells

Side Effects

Headache, confusion, nausea, vertigo, diarrhea or constipation, depression, rash, blurred vision, malaise, decreased libido

Adverse Reactions

Life-threatening: Hepatotoxicity, cardiac dysrhythmias, blood dyscrasias

A, Adult; *C,* child; *d,* day; *h,* hour; *h.s.,* at bedtime; *IM,* intramuscular; *IV,* intravenous; *maint,* maintenance; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life.

TABLE 48-5 ANTIULCER DRUGS: HISTAMINE$_2$ BLOCKERS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
cimetidine (Tagamet)	A: PO: 200 mg q.i.d. OR 800 mg h.s.; maint: 300 mg h.s. IV: 300 mg q6-8h diluted in 50 mL (administered over 15-30 min) IV: continuous infusion: 37.5 mg/h over 24 h; *max:* 900 mg/d C: PO: 10-40 mg/kg/d divided q6h	For peptic ulcers (gastric and duodenal). First H$_2$ blocker marketed. Many drug interactions and side effects. Duration of action 4-6 h. Pregnancy category: B; PB: 20%; t½: 2 h
famotidine (Pepcid)	A: PO: 20 mg b.i.d. or 40 mg h.s.; maint: 20 mg h.s. IV: 20 mg b.i.d. diluted	For active duodenal ulcer. Inhibits gastric secretion. More potent than cimetidine. Pregnancy category: B; PB: 15%-20%; t½: 2.5-4 h
nizatidine (Axid)	A: PO: 150 mg b.i.d. or 300 mg h.s.; maint: 150 mg h.s.	Same as famotidine. Also used to treat gastroesophageal reflux. Give drug after meals or at bedtime. Do not give within 1 h of antacids. Pregnancy category: B; PB: 35%; t½: 1-2 h
ranitidine (Zantac)	See Prototype Drug Chart 48-2.	

A, Adult; *C,* child; *d,* day; *h,* hour; *h.s.,* at bedtime; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life.

- Monitor gastric pH (>5 is desired), blood urea nitrogen (BUN), and creatinine.
- Determine drug history; report probable drug-drug interactions.

Nursing Diagnoses

- Acute pain related to excess gastric secretion

Planning

- Patient's abdominal pain will decrease after 1 to 2 weeks of drug therapy.

Nursing Interventions

- Administer drug just before meals or at bedtime to decrease food-induced acid secretion.

- Be alert that older adults have less gastric acid and need reduced doses of drug. Metabolic acidosis must be prevented.
- Administer IV drug in 20 to 100 mL of solution.

Patient Teaching

General

- Teach patient to report pain, coughing, or vomiting of blood.
- Advise patient to avoid smoking, because it can hamper effectiveness of drug.
- Remind patient that drug must be taken exactly as prescribed to be effective.
- Direct patient to separate ranitidine and antacid dosage by at least 1 hour.
- Warn patient not to drive a motor vehicle or engage in dangerous activities until stabilized on the drug.
- Tell patient that drug-induced impotence and gynecomastia are reversible.
- Educate patient in use of relaxation techniques to decrease anxiety.

Diet

- Teach patient to eat foods rich in vitamin B_{12} to avoid deficiency as a result of drug therapy.
- Alert patient to avoid foods and liquids that cause gastric irritation, such as caffeine-containing beverages, alcohol, and spices.

Cultural Considerations

- Respect patient's cultural beliefs and alternative methods for treating GI discomfort. Discuss safety of these methods and use of drugs prescribed to heal and lessen symptoms.
- Recognize that patients of various cultural backgrounds may need guidance in understanding the disease process of their GI disturbance. Use of a written plan of care with modifications should be considered.

Evaluation

- Determine effectiveness of drug therapy and presence of any side effects or adverse reactions. Patient should be free of pain, and healing should progress.

Proton Pump Inhibitors (Gastric Acid Secretion Inhibitors, Gastric Acid Pump Inhibitors)

PPIs suppress gastric acid secretion by inhibiting the hydrogen/potassium adenosine triphosphatase (ATPase) enzyme system located in the gastric parietal cells. They tend to inhibit gastric acid secretion up to 90% greater than the H_2 blockers (histamine antagonists). These agents block the final step of acid production.

Omeprazole (Prilosec) was the first PPI marketed, followed by lansoprazole (Prevacid), rabeprazole (Aciphex), pantoprazole (Protonix), esomeprazole (Nexium), and dexlansoprazole (Dexilant), a delayed-release oral capsule. These agents are effective in suppressing gastric acid secretions and are used to treat peptic ulcers and GERD. With lansoprazole, ulcer relief usually occurs in 1 week. Rabeprazole is more effective in treating duodenal ulcers than gastric ulcers, but it is most effective for treating GERD and hypersecretory disease (Zollinger-Ellison syndrome). Pantoprazole is prescribed to treat short-term erosive GERD. Intravenous pantoprazole is also reported as effective in treating Zollinger-Ellison syndrome. Esomeprazole has the highest success rate for healing erosive GERD, more so than omeprazole. Omeprazole promotes irreversible hydrogen or potassium ATPase inhibition until new enzyme is synthesized, which could take days, whereas rabeprazole causes reversible ATPase inhibition. Dexlansoprazole is prescribed to treat erosive esophagitis and symptomatic nonerosive GERD. All PPIs in large doses can be combined with antibiotics to treat *H. pylori*. Prototype Drug Chart 48-3 lists the pharmacologic data for esomeprazole.

SAFETY: Preventing Medication Errors

Do not confuse …

- **Protonix** (proton pump inhibitor) with **Lotronex** (serotonin 5-HT3 receptor antagonist used for irritable bowel syndrome)
- **Aciphex** (proton pump inhibitor) with **Aricept** (Alzheimer's agent)
- **Nexium** (proton pump inhibitor) with **Nexavar** (biologic response modifier) **Rabeprazole** (proton pump inhibitor) with **Aripiprazole** (atypical antipsychotic)
- **Misoprostol** (antiulcer agent) with **mifepristone** (postcoital contraceptive agent)

Two combination medications involving PPIs are omeprazole with sodium bicarbonate (Zegerid) and esomemprazole with Naproxen (Vimovo). Zegerid is the only drug given to prevent stress ulcers in critically ill patients. It also is used to treat GERD, erosive esophagitis, and gastric or duodenal ulcers. Zegerid can now be found over the counter as well. Vimovo is an immediate-release PPI layered over an enteric-coated NSAID in one tablet used to prevent NSAID-associated gastric ulcers.

Pharmacokinetics and Pharmacodynamics The duration of action for esomemprazole is 24 hours. These drugs have a short half-life and are highly protein-bound (97%). PPIs should usually be taken before meals. Caution should be used in patients with hepatic impairment; liver enzymes should be monitored. Possible side effects include headache, dizziness, diarrhea, abdominal pain, and rash. Prolonged use of PPIs may increase the risk for cancer, although this has only been proven in mice, not humans.

Table 48-6 lists the PPIs and their dosages, uses, and considerations.

Drug Interactions. PPIs can enhance the action of digoxin, oral anticoagulants, certain benzodiazepines, and phenytoin, because they interfere with liver metabolism of these drugs.

PROTOTYPE DRUG CHART 48-3

Esomeprazole

Drug Class	**Dosage**
Antiulcer: proton pump inhibitor Trade Name: Nexium Pregnancy Category: B	Erosive esophagitis: A: PO: 20-40 mg/d for 4-8 wk, then 20 mg daily GERD: A: PO: 15 mg/d for 4 wk C: PO: 1-11 y: 1.5 mg/kg/d *max:* 30 mg/d *H. pylori:* A: PO: 40 mg b.i.d. for 2 wk in combination therapy for 10-14 d Duodenal ulcer: A: PO: 15 mg/d for 4 wk
Contraindications	**Drug-Lab-Food Interactions**
Hypersensitivity, pregnancy, lactation Caution: Hepatic disease	Drug: May decrease theophylline levels; sucralfate decreases lansoprazole bioavailability; may interfere with absorption of ampicillin, ketoconazole, digoxin Food: Food decreases peak levels
Pharmacokinetics	**Pharmacodynamics**
Absorption: Rapidly absorbed in GI tract Distribution: PB: 97% Metabolism: $t\frac{1}{2}$: 1.5 h Excretion: Primarily in urine; also in bile and feces	PO: Onset: 2 h Peak: 1.5-3 h Duration: 24 h
Therapeutic Effects/Uses	
To treat peptic and duodenal ulcers, GERD, erosive esophagitis, *H. pylori,* and Zollinger-Ellison syndrome Mode of Action: Suppresses gastric acid secretion by inhibiting hydrogen/potassium ATPase enzyme in gastric parietal cells	
Side Effects	**Adverse Reactions**
Headache, dizziness, blurred vision, fatigue, thirst, dry mouth, increased appetite, anorexia, nausea, hiccups, diarrhea, constipation, rash	Elevated AST, ALT

A, Adult; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *ATP,* adenosine triphosphate; *b.i.d.,* two times a day; *C,* child; *d,* day; *GERD,* gastroesophageal reflux disease; *GI,* gastrointestinal; *h,* hour; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; $t\frac{1}{2}$, half-life; *wk,* weeks; *y,* years.

Pepsin Inhibitor (Mucosal Protective Drug)

Sucralfate (Carafate), a complex of sulfated sucrose and aluminum hydroxide, is classified as a pepsin inhibitor, or *mucosal protective drug.* It is nonabsorbable and combines with protein to form a viscous substance that covers the ulcer and protects it from acid and pepsin. This drug does not neutralize acid or decrease acid secretions.

The dosage of sucralfate is 1 gram, usually four times a day before meals and at bedtime. If antacids are added to decrease pain, they should be given either 30 minutes before or 30 minutes after the administration of sucralfate. Because sucralfate is not systemically absorbed, side effects are few; however, it can cause constipation. If the drug is stored at room temperature in an airtight container, it will remain stable for up to 2 years. Prototype Drug Chart 48-4 lists the pharmacologic data for sucralfate.

Pharmacokinetics Less than 5% of sucralfate is absorbed by the GI tract. It has a half-life of 6 to 20 hours. Ninety percent of the drug is excreted in feces.

Pharmacodynamics Sucralfate promotes healing by adhering to the ulcer surface. Onset of action occurs within 30 minutes, and duration of action is short. Sucralfate decreases the absorption of tetracycline, phenytoin fat-soluble vitamins, and the antibacterial agents, ciprofloxacin and norfloxacin. Antacids decrease the effects of sucralfate.

Nursing Process
Patient-Centered Collaborative Care

Antiulcer: Pepsin Inhibitor

Assessment

- Evaluate patient's pain, including type, duration, severity, and frequency. Ulcer pain usually occurs after meals and during the night.
- Determine patient's renal function. Report urine output of <600 mL/d or <30 mL/h.
- Assess for fluid and electrolyte imbalances.
- Measure gastric pH (>5 is desired).

Nursing Diagnosis

- Acute pain related to excess gastric secretion

TABLE 48-6 ANTIULCER DRUGS: PROTON PUMP INHIBITORS, PEPSIN INHIBITOR, AND PROSTAGLANDIN ANALOGUE

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Proton Pump Inhibitors (Gastric Acid Secretion Inhibitors)		
esomeprazole magnesium (Nexium)	See Prototype Drug Chart 48-3.	
lansoprazole (Prevacid)	A : PO: 15 mg/d	For treatment of duodenal and gastric ulcers, GERD, and esophagitis. Pregnancy category: B; PB: 97%-99%; t1/2: 1-1.5 h
omeprazole (Prilosec)	GERD and peptic ulcer: A: PO: 20 mg/d for 4-8 wk Hypersecretory: A: PO: Initially: 60 mg/d; may increase to 120 mg t.i.d.	For GERD, esophagitis, Zollinger-Ellison syndrome, and *H. pylori*. Poorly absorbed, only 35%-40% in circulation. Antacids can be taken with drug. Pregnancy category: C; PB: 95%; t½: 0.5-1.5 h
pantoprazole (Protonix)	A: PO/IV: 20-40 mg/d for up to 14 days	For gastric and duodenal ulcers and GERD. Action same as rabeprazole: suppresses gastric acid secretion. Pregnancy category: B; PB: 99%; t½: 3.5-10h.
rabeprazole (AcipHex)	Duodenal ulcer/GERD: A: PO: 20 mg/d Hypersecretory disease: A: PO: 60 mg/d or 60 mg b.i.d.	For duodenal ulcer, GERD, and hypersecretory syndrome (Zollinger-Ellison syndrome). Decreases gastric acid production by inhibiting hydrogen/potassium ATPase enzyme at gastric parietal cells. Pregnancy category: B; PB: 96.3%; t½: 1-2 h
dexlansoprazole (Dexilant)	A: PO: 30-60 mg/d for up to 8 weeks	For erosive esophagitis and symptomatic nonerosive GERD. May be given without regard to food. Pregnancy category: B; PB: 96%-98%; t½: 1-2 h
Pepsin Inhibitor		
sucralfate (Carafate)	See Prototype Drug Chart 48-4.	
Prostaglandin Analogue		
misoprostol (Cytotec)	A: PO: 100-200 mcg q.i.d. p.c.	Prevention of NSAID-induced gastric ulcer. May be taken during NSAID therapy, including with aspirin. Side effects include diarrhea, abdominal pain, flatulence, nausea, vomiting, constipation, and menstrual spotting. Short duration of action. Pregnancy category: X; PB: 85%; t½: 20-40 min

A, Adult; *a.c.,* before meals; *ATP,* adenosine triphosphate; *b.i.d.,* two times a day; *C,* child; *d,* day; *GERD,* gastroesophageal reflux disease; *h,* hour; *IV,* intravenous; *NSAIDs,* nonsteroidal antiinflammatory drugs; *p.c.,* after meals; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week; *y,* year; <, less than.

Planning

- Patient will have relief of abdominal pain after 1 to 2 weeks of antiulcer drug management.

Nursing Interventions

- Administer drug on empty stomach.
- Administer antacid 30 minutes before or 30 minutes after sucralfate. Allow 1 to 2 hours to elapse between sucralfate and other prescribed drugs; sucralfate binds with certain drugs (e.g., tetracycline, phenytoin), reducing their effect.

Patient Teaching

General

- Advise patient to take drug exactly as ordered. Therapy usually requires 4 to 8 weeks for optimal ulcer healing. Advise patient to continue to take drug even if feeling better.
- Increase fluids, dietary bulk, and exercise to relieve constipation.
- Educate patient in use of relaxation techniques.
- Monitor for severe, persistent constipation.
- Encourage need for follow-up medical care.
- Emphasize cessation of smoking as indicated.

Side Effects

- Direct patient to report pain, coughing, or vomiting of blood.

Diet

- Teach patient to avoid liquids and foods that can cause gastric irritation, such as caffeine-containing beverages, alcohol, certain fats, and spices.

PROTOTYPE DRUG CHART 48-4

Sucralfate

Drug Class
Antiulcer: pepsin inhibitor
Trade Names: Carafate, 🍁 Apo-Sucralfate
Pregnancy Category: B

Dosage
Active disease:
A: PO: 1 g q.i.d. 1 h a.c. and h.s.
Maint:
A: PO: 1 g b.i.d.

Contraindications
Hypersensitivity
Caution: Renal failure

Drug-Lab-Food Interactions
Drug: Decrease effects with tetracycline, phenytoin, fat-soluble vitamins, digoxin; altered absorption with ciprofloxacin, norfloxacin, antacids

Pharmacokinetics
Absorption: PO: Minimal absorption (<5%)
Distribution: PB: UK
Metabolism: t½: 6-20 h
Excretion: In urine

Pharmacodynamics
PO: Onset: 30 min
Peak: UK
Duration: 5 h

Therapeutic Effects/Uses
To prevent gastric mucosal injury from drug-induced ulcers (aspirin, NSAIDs); to manage ulcers
Mode of Action: In combination with gastric acid, forms a protective covering on the ulcer surface

Side Effects
Dizziness, headache, nausea, flatulence, constipation, dry mouth, rash, pruritus, sleepiness

Adverse Reactions
Hyperglycemia, hypomagnesemia

A, Adult; *a.c.,* before meals; *b.i.d.,* twice a day; *h,* hour; *h.s.,* at bedtime; *maint,* maintenance; *min,* minute; *NSAIDs,* nonsteroidal antiinflammatory drugs; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *UK,* unknown; 🍁, Canadian drug name; <, less than.

Cultural Considerations

- Greet the patient by name with appropriate title (e.g., Mr., Ms., Dr.). Wait until patient gives permission to use his or her first name.
- Orthodox Jewish men do not touch women other than their wives, so their failure to take a hand offered in greeting should not be interpreted as impoliteness.

Evaluation

- Determine the effectiveness of the antiulcer treatment and the presence of any side effects. Patient should be free of pain, and healing should progress.

Prostaglandin Analogue Antiulcer Drug

Misoprostol, a synthetic prostaglandin analogue, is a drug used to prevent and treat peptic ulcer. It appears to suppress gastric acid secretion and increase cytoprotective mucus in the GI tract. It causes a moderate decrease in pepsin secretion. Misoprostol is considered as effective as cimetidine. Patients who complain of gastric distress from NSAIDs such as aspirin or indomethacin prescribed for long-term therapy can benefit from misoprostol. When a patient takes high doses of NSAIDs, misoprostol is frequently recommended for the duration of the NSAID therapy. Misoprostol is contraindicated during pregnancy and for women of childbearing age.

Table 48-6 lists the pharmacologic data for the PPIs, pepsin inhibitors, and a prostaglandin analogue.

Proton pump inhibitors: *www.aafp.org/afp/20020715/273.html*

CRITICAL THINKING CASE STUDY

JH, a 48-year-old patient, complains of a gnawing, aching pain in the abdominal area that usually occurs several hours after eating. He says that over-the-counter antacids help somewhat but that the pain has recently intensified. Diagnostic tests indicate that the patient has a duodenal ulcer.

1. Differentiate between peptic ulcer, gastric ulcer, and duodenal ulcer. Explain your answer.
2. What are the predisposing factors related to peptic ulcers? What additional information do you need from JH?
3. What nonpharmacologic measures can you suggest to alleviate symptoms related to peptic ulcer?

The health care provider prescribed Mylanta 2 tsp to be taken 2 hours after meals, and ranitidine (Zantac) 150 mg twice a day. The dose of magnesium hydroxide and aluminum hydroxide with simethicone (Mylanta) is to be taken either 1 hour before or 1 hour after the ranitidine.

4. JH asks the nurse the purposes for Mylanta and ranitidine. What is the nurse's best response?
5. Why does the health care provider suggest that the patient take ranitidine with meals? Why should Mylanta and ranitidine not be taken at the same time?
6. In what ways are ranitidine and cimetidine (Tagamet) the same, and how do they differ? Explain your answer.
7. As part of patient teaching, the nurse discusses side effects of ranitidine with JH. What is the most effective way to present this information? Develop a plan.

JH states that he drinks beer at lunch and has two gin and tonics in the afternoon. He states that the drinks help him relax.

8. What nursing intervention should be taken in regard to his alcohol intake?
9. What foods should he avoid?

A week later JH states that he discontinued the prescribed medications because he "felt better." However, the pain recurred and he asked whether he should resume taking the medications.

10. What is the nurse's best response? What should be included in the patient teaching?

NCLEX STUDY QUESTIONS

1. A patient is diagnosed with peptic ulcer disease. The nurse realizes that which factor is a predisposing factor for this condition?
   a. *Helicobacter pylori*
   b. Hyposecretion of pepsin
   c. Decreased hydrochloric acid
   d. *Escherichia coli*
2. A student nurse is preparing to administer sucralfate (Carafate) to a patient. Which statement by the student nurse demonstrates understanding of sucralfate's mode of action?
   a. "Sucralfate neutralizes gastric acidity."
   b. "Gastric acid secretion is decreased by inhibiting histamine at H_2 receptors in parietal cells."
   c. "Gastric acid secretion is suppressed by inhibiting the hydrogen/potassium ATPase enzyme."
   d. "Sucralfate combines with protein to form a viscous substance that forms a protective covering of ulcer."
3. A patient is taking ranitidine (Zantac). What information should the nurse teach the patient about this drug? (Select all that apply.)
   a. Drug-induced impotence is irreversible.
   b. The drug must be administered 30 minutes before meals.
   c. The drug must be administered separately from an antacid by at least 1 hour.
   d. The drug must always be administered with magnesium hydroxide.
   e. Smoking should be avoided while taking this drug.
   f. Foods high in vitamin B_{12} should be increased in diet.
4. When a patient complains of pain accompanying a peptic ulcer, why should the nurse give an antacid?
   a. Antacids decrease GI motility.
   b. Antacids decrease gastric acid secretion.
   c. Antacids strengthen the lower esophageal sphincter's action.
   d. Antacids neutralize HCl and reduce pepsin activity.
5. A patient is taking famotidine (Pepcid) to inhibit gastric secretions. Which side effects of famotidine will the nurse teach the patient? (Select all that apply.)
   a. Diarrhea
   b. Dizziness
   c. Dry mouth
   d. Headaches
   e. Blurred vision
   f. Decreased libido
6. The patient is taking esomeprazole magnesium (Nexium) for an erosive GERD. Which should the nurse include in patient teaching?
   a. Take with breakfast daily.
   b. Healing should occur in one week.
   c. This medication decreases stomach acid secretion.
   d. Blood test to check kidney function should be done.

Answers: 1, a; 2, d; 3, c, e, f; 4, d; 5, b, d, f; 6, c.

UNIT XVI

Eye, Ear, and Skin Agents

Drugs used to treat eye and ear disorders are also discussed in other chapters. Antibiotics are covered in Chapter 29, Penicillins and Cephalosporins; Chapter 30, Macrolides, Tetracyclines, Aminoglycosides, and Fluoroquinolones; and Chapter 31, Sulfonamides. Unit XVI discusses in detail the agents used to treat disorders of the eye, ear, and skin. Chapter 49, Drugs for Eye and Ear Disorders, presents medications used to treat eye disorders, particularly glaucoma and ocular infections. Drugs used to treat ear disorders are also covered. Chapter 50, Drugs for Dermatologic Disorders, presents the agents used to treat skin conditions such as acne and psoriasis.

OVERVIEW OF THE EYE

The eyeballs, protected within the orbits of the skull, are controlled by the third, fourth, and sixth cranial nerves and are connected to six extraocular muscles. The eye has three layers: (1) the cornea and sclera; (2) the choroid, iris, and ciliary body; and (3) the retina. Figure XVI-1 illustrates the basic structures of the eye.

The cornea, the anterior covering of the eye, is transparent, enabling light to enter the eye. It has no blood vessels and receives nutrition from the aqueous humor. An abraded cornea is susceptible to infection. Loss of corneal transparency is usually caused by increased intraocular pressure (IOP).

The sclera is the opaque, white fibrous envelope of the eye. Within the sclera are the posterior chamber and the anterior chamber. The posterior chamber has a blind spot, which is not sensitive to light, around the optic nerve. The lens, held in place by ligaments, separates these two chambers. The normally transparent lens focuses light on the retina by changing its shape through a process called *accommodation.*

The anterior chamber, filled with aqueous humor secreted by the ciliary body, lies in front of the lens. The fluid flows into the anterior chamber through a space between the lens and iris. The excess fluid drains into the canal of Schlemm. An increase in IOP, resulting in glaucoma, occurs with increased production or decreased drainage of aqueous humor.

The choroid, iris, and ciliary body (thickened part of the vascular covering of the eye that provides attachment to ligaments and support to the lens) constitute the second layer. The choroid absorbs light. The iris surrounds the pupil and gives the eye its color. By dilating and constricting, the iris controls the quantity of light reaching the lens.

The retina, the third layer, consists of nerves, rods, and cones that serve as visual sensory receptors. The retina is connected to the brain via the optic nerve.

The eyebrows, eyelashes, eyelids, tears, and corneal and conjunctival reflexes all serve to protect the eye. Bilateral blinking occurs every few seconds during waking hours to keep the eye moist and free of foreign material.

OVERVIEW OF THE EAR

The ear is divided into the external, middle, and inner ear. Figure XVI-2 illustrates the basic structures of the ear.

The *external ear* consists of the pinna and the external auditory canal. The external auditory canal transmits sound to the tympanic membrane (eardrum), a transparent partition between the external and middle ear. The eardrum in turn transmits sound to the bones of the middle ear; it also serves a protective function.

The *middle ear,* an air-filled cavity, contains three auditory ossicles (malleus, incus, and stapes) that transmit sound waves to the inner ear. The tip of the malleus is attached to the eardrum; its head is attached to the incus, which is attached to the stapes. The Eustachian tube provides a direct connection to the nasopharynx and equalizes air pressure on both sides of the eardrum to prevent it from rupturing. Swallowing, yawning, and chewing gum help the Eustachian tube relieve pressure changes during airplane flights.

The *inner ear,* a series of labyrinths (canals), consists of a bony section and a membranous section. The vestibule, cochlea, and semicircular canals make up the bony labyrinth. The vestibular area is responsible for maintaining equilibrium and balance. The cochlea is the principal hearing organ.

Professional evaluation of ear problems is essential, because hearing loss can result from untreated disorders. Middle ear problems require prescription medications and are not treated with over-the-counter preparations.

OVERVIEW OF THE SKIN

Skin, the largest organ of the body, consists of two major layers: the *epidermis* (the outer layer of skin) and the *dermis* (the layer of skin beneath the epidermis). The functions of the skin include (1) protecting the body from the environment, (2) aiding in body temperature control, and (3) preventing body fluid loss.

FIGURE XVI–2 Basic structures of the ear.

The epidermis has four layers: (1) the basal layer (stratum germinativum), the deepest layer lying over the dermis; (2) the spinous layer (stratum spinosum); (3) the granular layer (stratum granulosum); and (4) the cornified layer (stratum corneum), the outer layer of the epidermis. As the epidermal cells migrate to the surface, they die, and their cytoplasm converts to keratin (hard and rough texture), forming keratinocytes. Eventually the keratinocytes slough off as new layers of epidermal cells migrate upward.

The dermis has two layers: (1) the papillary layer, next to the epidermis, and (2) the reticular layer, which is the deeper layer of the dermis. The dermal layers consist of fibroblasts, collagen fibers, and elastic fibers. The collagen and elastic fibers give the skin its strength and elasticity. Within the dermal layer, there are sweat glands, hair follicles, sebaceous glands, blood vessels, and sensory nerve terminals. Figure XVI-3 shows the layers of the skin.

The subcutaneous tissue, primarily fatty tissue, lies under the dermis. Besides fatty cells, subcutaneous tissue contains blood and lymphatic vessels, nerve fibers, and elastic fibers. It supports and protects the dermis.

OBJECTIVES

- Describe the medication groups commonly used for disorders of the eye and ear.
- Discuss the mechanisms of action, route, side effects and adverse reactions, and contraindications for selected drugs in each group.
- Develop teaching plans for the drug groups presented.
- Describe the nursing process related to drugs used in treating and managing disorders of the eye and ear.

OUTLINE

Drugs for Disorders of the Eye
  Diagnostic Stains
  Topical Anesthetics
  Antiinfectives
  Antiinflammatories

DRUGS FOR DISORDERS OF THE EYE

Problems associated with the eyes may occur as the result of injuries, infections, and specific eye disorders like glaucoma and macular degeneration. Most drugs used to treat these conditions are topical medications in formulations developed specifically for sensitive eyes. Drugs designed to be applied to the eyes are known as **ocular** or **ophthalmic** drugs.

Diagnostic Stains

Diagnostic stains (Table 49-1) are frequently used to locate lesions or foreign objects, evaluate dry eye, or evaluate eye changes from poorly fitting contact lenses. Stains may be combined with local anesthetics to allow more thorough examination when pain is present. Patients should be informed that these drugs may stain nasal secretions if the **lacrimal ducts** (tear ducts) are patent; they can also discolor soft contact lenses. Contact lenses should be removed before administration. After the procedure, the stain should be flushed out with normal saline; contact lenses can be replaced after 1 hour.

Topical Anesthetics

Topical anesthetics are used in selected aspects of a comprehensive eye examination and in a variety of ophthalmic procedures. The two most common topical ophthalmic anesthetics are proparacaine HCl and tetracaine HCl (Pontocaine). Both medications are administered as drops.

Corneal anesthesia is achieved within 1 minute and generally lasts about 15 minutes. The blink reflex is temporarily lost; therefore, the corneal epithelium may become dry. To protect the eye, a patch is usually worn until the effects of the drug are gone. However, because patching of the eye may impede healing, the patch should be removed once sensation and the blink reflex return.

TABLE 49-1 **DIAGNOSTIC STAINS FOR EYE DISORDERS**

DIAGNOSTIC AID	PURPOSE
Fluorescein sodium (Fluorescite)	Demonstration of defects in corneal epithelium. When viewed through the cobalt blue filter of the ophthalmoscope or under a Wood's lamp, corneal scratches and lesions fluoresce a bright yellow-green.
Rose Bengal	Demonstration of defects and dryness of the conjunctival tissues. Defects are stained a pink-violet color. Stinging and mild tissue toxicity limits use.
Lissamine green	Demonstration of defects and dryness of the conjunctival tissues. Defects are stained green. Because it is not toxic to tissues and does not usually cause stinging, it has largely replaced Rose Bengal.

Ophthalmic anesthetics are *not* to be self-administered by the patient. Repeated doses are given only under strict medical supervision.

Antiinfectives

Antiinfectives (Table 49-2) are frequently used for eye infections. **Conjunctivitis,** an inflammation of the delicate membrane covering the eye and inner eyelids, is the most common eye condition requiring antibiotic therapy. Examples of other ocular conditions treated with ophthalmic antiinfective drugs include the following:

- Blepharitis (infection of margins of eyelid)
- Chalazion (infection of meibomian glands of the eyelids that may produce cysts, causing blockage of the ducts)
- Bacterial and fungal endophthalmitis (infection and inflammation of structures of the inner eye)
- Hordeolum (local infection of eyelash follicles and glands on lid margins, also known as a *stye*)
- Infectious keratitis (corneal infection and inflammation)
- Infectious uveitis (infection of vascular layer of eye [ciliary body, choroid, and iris])

Before administering ophthalmic antiinfectives, the nurse should screen the patient for previous allergic reactions. Noninfectious conjunctivitis and local skin and eye irritation are possible side effects of topical antiinfective drugs.

Antiinflammatories

Inflammatory conditions of the eye often require treatment with antiinflammatory drugs (Table 49-3) such as NSAIDs and corticosteroids. If the inflammation is secondary to a bacterial or fungal infection, an antibiotic or antifungal agent is included in the medication regimen. Antiinflammatories should not be given if the patient has a viral infection.

When allergies are the cause of eye inflammation, ophthalmic antihistamines and mast cell stabilizers are commonly prescribed to treat the underlying cause. Antihistamines block histamine from activating histamine receptors in the tissues. Examples of ophthalmic antihistamines include emedastine (Emadine) and epinastine (Elestat). Mast cell stabilizers prevent mast cells from breaking open and releasing histamine and other inflammatory mediators. Ophthalmic mast cell stabilizers include cromolyn (Crolom) and nedrocromil ophthalmic (Alocril). Some drugs, such as azelastine (Optivar), epinastine, ketotifen (Zaditor) and olopatadine (Patanol), have both antihistamine and mast cell stabilizer effects. Burning, headache, and stinging may occur in some patients and are the most frequent adverse effects of these drugs.

Decongestants

Eye inflammation typically presents with redness due to vascular congestion of the conjunctiva. Ophthalmic decongestants are vasoconstrictors that manage these effects by narrowing these blood vessels. Examples of ophthalmic decongestants are phenylephrine (Neo-Synephrine Ophthalmic), naphazoline (Clear Eyes), tetrahydrozoline (Opti-Clear), and oxymetazoline (Ocuclear). If these are absorbed

TABLE 49-2 OPHTHALMIC ANTIINFECTIVES

GENERIC (BRAND)	ROUTE AND DOSAGE*	USES AND CONSIDERATIONS
Antibacterials		
chloramphenicol	A/C: Ophthalmic: Instill 1-2 gtt or ½-inch ribbon of oint q3-4h for 48 h; increase interval to b.i.d./t.i.d.	For severe ophthalmic infections that are unresponsive to other antibiotics. Effective against gram-negative and gram-positive bacteria. Boxed warning: Bone marrow suppression and deaths have resulted from topical administration. Continue treatment for at least 48 h after eye appears normal. Contact lenses should not be worn for duration of treatment. Pregnancy category: C
ciprofloxacin (Ciloxan) 5 mg/mL sol	Bacterial conjunctivitis: Solution: A/C: >1 y: 1-2 gtt q2h while awake for 2 d, then q4h while awake for 5 d Bacterial conjunctivitis: Ointment: A/C: >2 y: ½-inch ribbon t.i.d for 2 d, then ½-inch ribbon b.i.d for 5 d Corneal ulcer: A/C: >1 y: Day 1: 2 gtt q15min for 6 h, then 2 gtt q30min for rest of day Day 2: 2 gtt q1h Days 3-14: 2 gtt q4h	For bacterial conjunctivitis and corneal ulceration. Contact lenses should not be worn for duration of treatment. Pregnancy category: C
erythromycin	Chlamydial conjunctivitis or ophthalmia neonatorum caused by *Chlamydia trachomatis:* Oral dosage: Neonates/infants: CDC recommends 50 mg/kg/d PO divided q.i.d. for 14 d. Second course may be required. CDC states that topical therapy alone is inadequate and unnecessary when systemic therapy is administered. Ophthalmia neonatorum caused by *Neisseria gonorrhoeae* or *Chlamydia trachomatis:* Ophthalmic dosage: A: Instill 1-2 gtt of 0.25% sol into each affected eye b.i.d., or instill 1-2 gtt of 0.5% sol into each affected eye once/d. Greater than 1 gtt of 0.5% preparation b.i.d. generally does not further reduce IOP and is not recommended. Neonates: Apply a ribbon of 0.5% ophthalmic ointment into each lower conjunctival sac no later than 1 hour after birth	For chlamydial conjunctivitis caused by *C. trachomatis* and ophthalmia neonatorum caused by *C. trachomatis* or *N. gonorrhoeae*. Prolonged use can lead to acquired sensitivity. Contact lenses should not be worn for duration of treatment. Pregnancy category: B
gentamicin sulfate (Garamycin Ophthalmic, Gentak)	A/C: Sol 0.3%: 1-2 gtt q4h; may increase to 2 gtt q1h for severe infections Oint 0.3%: ½-inch ribbon b.i.d./t.i.d.	For blepharitis, blepharo-conjunctivitis, bacterial conjunctivitis, corneal ulcer, dacryocystitis, keratitis, kerato-conjunctivitis, and acute meibomianitis. Ophthalmia neonatorum secondary to *N. gonorrhoeae* May cause ototoxicity (toxic effect on eighth cranial nerve), which may be permanent. Contact lenses should not be worn for duration of treatment. Pregnancy category: C
levofloxacin	A: 1-2 gtts q2h; *max:* 8 doses/d for 1-2 d; then q4h; *max:* 4 doses/d for 5 d	For bacterial conjunctivitis and corneal ulcers (Systemic therapy is required for treatment of hordeolum, dacryocystitis, and meibomianitis). Contact lenses should not be worn for duration of treatment. Pregnancy category: C
silver nitrate 1% (Dey-Drop)	Neonate: Instill 2 gtt in each eye within 1 h of birth	For prophylaxis of ophthalmia neonatorum caused by *N. gonorrhoeae* Pregnancy category: C
sulfacetamide (Bleph-10)	A/C: >12 y: Sol: 1 gtt q1-3h while awake; then q3-4h while sleeping	For conjunctivitis, corneal ulcer, and adjunctive therapy for chlamydial conjunctivitis. Effectiveness of sulfonamides decreased in presence of PABA and purulent drainage; hence, remove exudates before instilling drops. Contact lenses should not be worn for duration of treatment. Pregnancy category: C

TABLE 49-2 OPHTHALMIC ANTIINFECTIVES—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE*	USES AND CONSIDERATIONS
tobramycin (Tobrex)	A/C: >12 y: Oint 0.3%: ½-inch ribbon b.i.d./t.i.d Sol 0.3%: 1-2 gtt q4h For severe infections: Oint: ½-inch ribbon q3-4h Sol: 2 gtt q30-60min until improvement, then decrease frequency	For external ocular infections. Contact lenses should not be worn for duration of treatment. Pregnancy category: D
tetracycline HCl	A: Instill 1-2 gtt b.i.d./q.i.d. A: Instill ½-inch ribbon q2-12h	Bacteriostatic action; alternative to silver nitrate for prevention of ophthalmia neonatorum. Contact lenses should not be worn for duration of treatment. Pregnancy category: D
triple antibiotic ophthalmic ointment (neomycin, polymyxin B Sulfate, bacitracin ophthalmic)	A/C: >12 y: 1 cm applied in conjunctival sac q3-4h	Combination antibiotic effective against many gram-positive and gram-negative organisms. Do not use longer than 10 d. Contact lenses should not be worn for duration of treatment. Pregnancy category: C
Antifungals		
natamycin (Natacyn Ophthalmic)	A/C: Sol 5%: 1 gt q2h for 3-4 d; then 1 gt q3h for 14-21 d	May cause transient stinging or temporary blurring of vision. Pregnancy category: C
Antivirals		
idoxuridine (IDU, Herplex Liquifilm)	A/C: Sol 1%: Initially: 1 gt q1h during day and q2h at night; when definite improvement occurs, use 1 gt q2h during day and q4h at night; continue 3-7 d after healing occurs Oint 0.5%: Place ½-inch ribbon q4h while awake	For cytomegalovirus and herpes simplex keratitis. Store in refrigerator; do not mix with boric acid. Discontinue if no response in 1 wk. Pregnancy category: C
trifluridine (Viroptic)	A: Sol 1%: Instill 1 gt into infected eye q2h while awake; *max:* 9 gtt/d until corneal ulcer reepithelialized; then 1 gt q4h for 7 d; *max:* 21 d of treatment	For herpetic ophthalmic infections and keratoconjunctivitis caused by HSV-1 and HSV-2. Pregnancy category: C

*To minimize systemic absorption, gently apply pressure on inner canthus.

TABLE 49-3 OPHTHALMIC ANTIINFLAMMATORIES

GENERIC (BRAND)	ROUTE AND DOSAGE*	USES AND CONSIDERATIONS
Nonsteroidal Antiinflammatory Drugs (NSAIDs)		
diclofenac sodium (Voltaren Ophthalmic)	A: 1 gt to affected eye q.i.d. for 2 wk; start 24 h after cataract surgery	For postoperative inflammation and photophobia after cataract surgery. May increase bleeding and delay healing. Increased risk for keratitis and elevated IOP. Pregnancy category: C
flurbiprofen sodium (Ocufen)	A: Instill 1 gt q30min starting 2 h before surgery; total dose is 4 gtt	For prevention of intraoperative miosis. May increase bleeding and delay healing. Pregnancy category: C
ketorolac tromethamine (Acular)	Allergic conjunctivitis: A/C >2 y: Sol 0.5%: Instill 1 gt q.i.d. Following cataract surgery: A: Begin q.i.d 24 h postop, and continue for 2 weeks	For relief of itching due to allergic conjunctivitis and management of inflammation post–cataract surgery. May increase bleeding and delay healing. Pregnancy category: C
suprofen (Profenal) (Maple Leaf)	Preoperative: A: Instill 2 gtt in sac q4h while awake on day preceding surgery; instill 2 gtt in conjunctival sac at 3, 2, and 1 h before surgery	For prevention of intraoperative miosis. May increase bleeding and delay healing. Pregnancy category: C
Corticosteroids		
dexamethasone (Maxidex)	A/C: Oint: Apply into conjunctival sac t.i.d./q.i.d.; gradually decrease to discontinue Susp: Instill 2 gtt q1h while awake and q2h during night; taper to q3-4h; then t.i.d./q.i.d.	For uveitis; allergic conditions; and inflammation of conjunctiva, cornea, and lids. Not recommended for minor abrasions and wounds. May delay healing. Avoid use with viral infections. Pregnancy category: C

TABLE 49-3 OPHTHALMIC ANTIINFLAMMATORIES—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE*	USES AND CONSIDERATIONS
medrysone (HMS Liquifilm)	A/C: Susp: Initially: Instill 1 gt in conjunctival sac q1-2h (1-2 d); then 1 gt b.i.d./q.i.d.	For allergic conditions, burns, and inflammation of conjunctiva, cornea, and lids. May delay healing. Avoid use with viral infections. Pregnancy category: C
prednisolone acetate (Econopred Plus)	A: Initially instill 1-2 gtt in conjunctival sac q1h while awake, q2h during night until desired effect; maint: 1 gt q4-6h Susp: 0.125% and 1%	For uveitis; allergic conditions; burns; and inflammation of conjunctiva, cornea, and lids. May delay healing. Avoid use with viral infections. Pregnancy category: C
prednisolone sodium phosphate	A/older adults: Sol 0.125% and 1%: 1-2 gtt q1h during day; q2h at night; with response, give 1 gt q4-6h Oint: thin coat t.i.d./q.i.d.; with response, decrease to b.i.d., then daily	To prevent or decrease tissue response to inflammatory process. May delay healing. Avoid use with viral infections. Pregnancy category: C
Ophthalmic Antihistamines		
emedastine (Emadine)	A/C ≥3 y: 1 gtt up to 4 times/d	For allergic conjunctivitis. Wait 10 minutes after administration before inserting contact lenses. Pregnancy category: B
epinastine (Elestat)	A/C ≥3 y: 1 gtt b.i.d.	For allergic conjunctivitis Wait 10 minutes after administration before inserting contact lenses. Pregnancy category: C
Ophthalmic Mast Cell Stabilizers		
cromolyn (Crolom)	A/C >4 y: 1-2 gtt in each eye 4-6 times/d	For allergic conjunctivitis Contact lenses should not be worn for duration of therapy Pregnancy category: B
nedrocromil ophthalmic (Alocril)	A/C ≥3 y: 1-2 gtt b.i.d.	For allergic conjunctivitis About 40% experience headache; 10%-30% experience burning sensation Contact lenses should not be worn for duration of therapy Pregnancy category: B
Ophthalmic Drugs with Both Antihistamines and Mast Cell Stabilizer Properties		
azelastine (Optivar)	A/C ≥3 y: 1 gtt in each eye b.i.d.	For allergic conjunctivitis. Has both antihistamine and mast-cell stabilizing actions. 11.5% experience drowsiness; enhances CNS depressants Wait 10 minutes after administration before inserting contact lenses. Pregnancy category: C
epinastine (Elestat)	A/C ≥3 y: 1 gtt each eye b.i.d.	For allergic conjunctivitis. Has both antihistamine and mast-cell stabilizer actions 1%-10% develop coldlike symptoms. Wait 10 minutes after administration before inserting contact lenses. Pregnancy category: C
ketotifen (Zaditor)	A/C ≥3 y: 1 gtt in each eye q8-12h	For allergic conjunctivitis. 10%-25% experience mild hyperemia and headache. Wait 10 minutes after administration before inserting contact lenses. Pregnancy category: C
olopatadine (Patanol)	A/C ≥3 y: 0.1% sol: 1 drop in each affected eye b.i.d. at an interval of 6-8 h	For allergic conjunctivitis. May potentiate CNS depressants if systemically absorbed. Wait 10 minutes after administration before inserting contact lenses. If eyes turn red, do not wear contact lenses. Pregnancy category: C

*To minimize systemic absorption, gently apply pressure on inner canthus.

A, Adult; *b.i.d.,* twice a day; *C,* child; *d,* day; *gt,* drop; *gtt,* drops; *h,* hour; *maint,* maintenance; *max,* maximum; *min,* minute; *NA,* not applicable; *oint,* ointment; *PB,* protein-binding; *q.i.d.,* four times a day; *sol,* solution; *susp,* suspension; *t½,* half-life; *t.i.d.,* three times a day; *q.i.d.,* four times a day; *wk,* week.

in significant amounts, their sympathetic nervous system effects may pose problems for patients with hypertension. Patients who have narrow-angle glaucoma should not use these drugs because they may contribute to acute angle-closure, which is a medical emergency.

Lubricants

Eye lubricants replace tears to alleviate discomfort associated with eye dryness. They are also used to moisten contact lenses and artificial eyes. During anesthesia and in acute or chronic central nervous system (CNS) disorders that result in unconsciousness or decreased blinking, lubricants keep eyes moist and maintain the integrity of the epithelial surface of the eye.

Most lubricants are available over the counter (OTC) in both liquid and ointment form. Popular lubricants include Isopto Tears, Tearisol, Ultra Tears, Tears Naturale, Tears Plus, Lens Mate, and Lacri-Lube. While these agents typically are safe, the nurse must be alert to potential allergic reactions to preservatives in lubricants.

Immunosuppressants

Cyclosporine ophthalmic emulsion (Restasis) relieves dry eyes by a mechanism that is different from lubricants. It is prescribed for patients who have decreased tear production due to inflammation. Cyclosporine suppresses the immune response that leads to inflammation, allowing tear production to resume.

Ophthalmic corticosteroids are another type of immunosuppressant. Corticosteroids are used to treat a number of conditions that manifest as significant eye inflammation. Examples include prednisolone (Pred Forte), dexamethasone (Maxidex), loteprednol (Lotemax), rimexolone (Vexol), and fluorometholone (FML). Refer to Chapter 25 for more information on corticosteroids.

Because they suppress the immune response, ophthalmic immunosuppressants should not be given to patients with bacterial infections of the eye unless accompanied by an antibiotic that treats the underlying infection. Ophthalmic immunosuppressants are contraindicated for viral eye infections such as herpes.

Antiglaucoma Agents

Glaucoma is an eye condition in which optic nerve damage occurs as a result of increased **intraocular pressure (IOP),** which is a buildup of pressure within the eye that occurs when there is too much aqueous humor. Without treatment, permanent loss of vision can occur.

Typically, as aqueous humor is formed, excess fluid drains though the trabecular meshwork structure of the eye and out the canal of Schlemm, with a much smaller fraction of the fluid exiting through the uveoscleral structure at the root of the iris (Figure 49-1, *A*). In glaucoma, excess fluid is prevented from draining through the trabecular structure.

There are two types of glaucoma. In **open-angle glaucoma,** the trabecular network becomes clogged (Figure 49-1, *B*). Over time, as blockage of the trabecular network worsens, the IOP gradually increases.

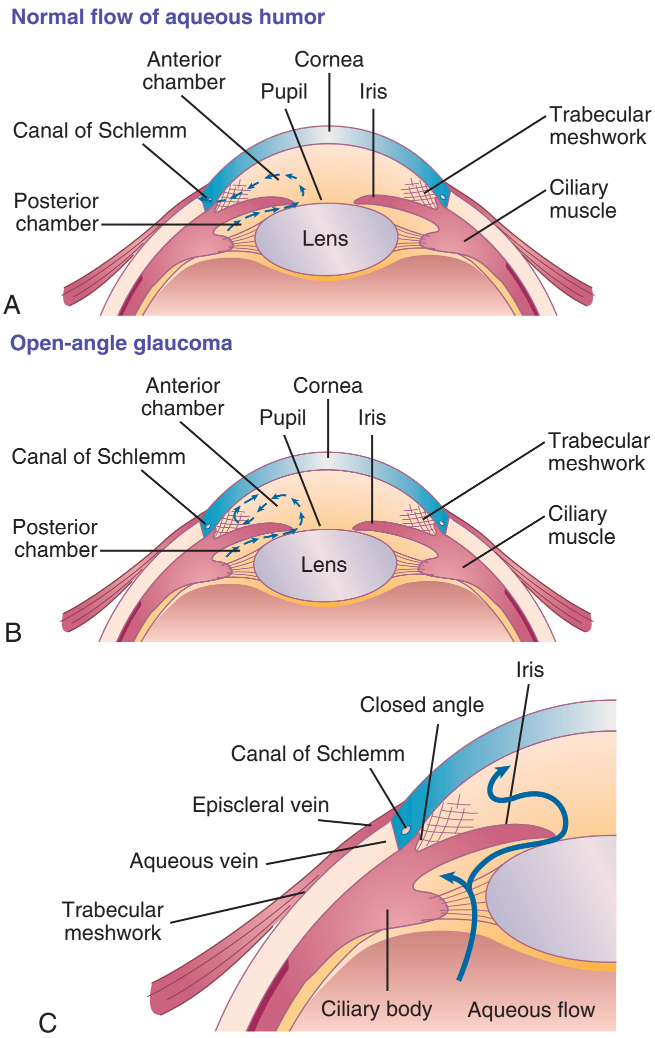

FIGURE 49–1 *A,* Normal flow of aqueous humor. *B,* Open-angle glaucoma. *C,* Closed-angle glaucoma.

In **narrow-angle glaucoma**, also known as closed-angle or angle-closure glaucoma, the iris bows and blocks the trabecular network by narrowing or closing the angle where fluid typically exits the eye (Figure 49-1, *C*). Because the excess aqueous humor cannot drain, it builds up within the eye, increasing IOP. Management of narrow-angle glaucoma is often surgical; however, pharmacologic management is sometimes indicated.

Glaucoma is further classified as either primary or secondary. Primary glaucoma occurs due to a pathologic change within the eye that happens without a known cause. Primary open-angle glaucoma (POAG), the most common type of glaucoma, is a chronic condition that develops slowly over time as the trabecular meshwork becomes clogged for unknown reasons. Secondary glaucoma occurs in response to a known cause such as injury, disease, or medication. While a number of drugs can increase the risk of secondary glaucoma, those that cause pupillary dilation are particularly problematic because they give the iris more flexibility to move in a way that blocks the trabecular meshwork. Certain herbal preparations can also create problems when given to patients who have glaucoma (Herbal Alert 49-1).

HERBAL ALERT 49-1

Herbs and Antiglaucoma Agents

The following herbs should be avoided in patients with glaucoma: bitter orange, blood root, celandine, coffee, corkwood, ephedra, goldenseal, and jimsonweed. Because all herbs have inherent risks, it is important to receive approval from the patient's health care provider before recommending herbal preparations.

Antiglaucoma drugs belong to one of the following categories: **prostaglandin analogues,** beta-adrenergic blockers, alpha-adrenergic agonists, cholinergic agents, carbonic anhydrase inhibitors, or systemic hyperosmotic drugs. Prostaglandin analogues and beta-adrenergic blockers are typically first-line therapy, followed by alpha-adrenergic agonists. Each category acts in different ways to decrease IOP.

Prostaglandin Analogues

Prostaglandin analogues (Table 49-4) are first-line drugs used primarily in the treatment of open-angle glaucoma; however, studies suggest a role in management of narrow-angle glaucoma, as well. These drugs decrease IOP by improving trabecular outflow and by increasing the uveoscleral pathway, which is an alternate pathway of aqueous humor outflow. Examples of prostaglandin analogues include bimatoprost (Lumigan), latanoprost (Xalatan) (Prototype Drug Chart 49-1), tafluprost (Zioptan), and travoprost (Travatan).

Side Effects and Adverse Reactions. Prostaglandin analogues used for glaucoma have unique side effects. These drugs gradually change the color of the iris by increasing brown pigmentation. This effect, most noticeable in individuals with green-brown and yellow-brown irises, may be permanent. Darkening of the eyelids may also occur. Another unusual side effect is the development of eyelash hypertrichosis, which is a growth in the number, length, thickness, and pigmentation of eyelashes. Up to 15% of patients may also develop blurred vision, redness of the conjunctiva, and itching or stinging of the eye. Systemic effects are rare, however, and these drugs are generally better tolerated than alternative antiglaucoma drugs.

Cholinergic Agents

Ophthalmic cholinergic agents cause **miosis**, which is a constriction of the pupil, and contraction of the ciliary muscle. These actions result in a widening of the trabecular meshwork to improve outflow of excess aqueous humor. Additionally, as the pupil constricts, it straightens the iris, thus opening or widening the angle to relieve narrow-angle glaucoma. There are two types of cholinergics: cholinergic agonists and cholinesterase inhibitors. Although their outcomes are the same, cholinergic agonists and cholinesterase inhibitors differ in their mechanism of action.

Cholinergic agonists are direct-acting cholinergics. Direct-acting cholinergics directly stimulate cholinergic receptors.

TABLE 49-4 PROSTAGLANDIN ANALOGUES USED TO TREAT GLAUCOMA

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
latanoprost (Xalatan)	A: 1 gt 0.005% sol h.s.	Decreases IOP in open-angle glaucoma; may have a role in narrow-angle glaucoma, but more studies needed. Few adverse effects. Not recommended for patients with torn or absent lens or with eye trauma. Do not insert contact lenses for 15 minutes after administration. Pregnancy category: C
bimatoprost (Lumigan)	A: 1 gt 0.03% sol h.s.	Decreases IOP in open-angle glaucoma; may have a role in narrow-angle glaucoma, but more studies are needed. Few adverse effects. Not recommended for patients with torn or absent lens or with eye trauma. May worsen intraocular inflammation. Onset is 4 h, and peak action occurs in 4-12 h. Pregnancy category: C
travoprost (Travatan Z)	A: 1 gt 0.004% sol h.s.	Decreases IOP in open-angle glaucoma; may have a role in narrow-angle glaucoma, but more studies needed. Few adverse effects. Avoid use in patients with torn or absent lens or with eye trauma. More effective in African Americans than in non–African Americans. Onset is 2 h, with peak action occurring in 12 h.
tafluprost (Zioptan)	A: 1 gt every evening	Decreases IOP in open-angle glaucoma; may have a role in narrow-angle glaucoma, but more studies needed. Few adverse effects. Avoid use in patients with torn or absent lens or with eye trauma. Information on contact lenses not available in prescribing information/package insert.

A, Adult; *b.i.d.,* twice a day; *gt,* drop; *h,* hour; *h.s.,* at bedtime; *IOP,* intraocular pressure; *sol,* solution.

PROTOTYPE DRUG CHART 49-1

Latanoprost

Drug Class

Prostaglandin analogue

Generic Name: Latanoprost

Trade Name: Xalatan

Pregnancy Category: C

Dosage

1 gtt (1.5 mcg)/d in affected eye(s)

Contraindications

No absolute contraindication. Use caution in patients with a torn or absent lens, intraocular inflammation, or risk of macular edema.

Drug is absorbed by soft contact lenses, so advise patient to use alternate means of vision correction.

Indicated only for open-angle glaucoma because only limited testing has taken place with narrow-angle glaucoma, neovascular glaucoma, and inflammatory glaucoma.

Patients with history of diabetic retinopathy who took latanoprost experienced retinal detachment, retinal embolus, and vitreous hemorrhage. This may or may not be related to the latanoprost, but caution is urged.

Drug-Lab-Food Interactions

Drugs: Concomitant administration with eyedrops containing thimerosal causes latanoprost to precipitate out of solution.

Bromfenac ophthalmic solution, an NSAID, may reduce latanoprost's ability to lower IOP.

Bimatoprost ophthalmic solution (Latisse), which is prescribed to promote growth of eyelashes, may decrease the ability of latanoprost to lower IOP.

Pharmacokinetics

Absorption: Latanoprost is a prodrug. After absorption through the cornea, it is hydrolyzed to its active form.

Distribution: 0.16 ± 0.02 L/kg. Primary measurable concentration is in the eye. Levels are often undetectable in serum.

Metabolism: Hepatic

Excretion: Primarily in urine (88%) with remainder in feces

Pharmacodynamics

Onset: 3-4 h

Peak: 8-12 h

Duration: 24 h

Therapeutic Effects/Uses

Reduction of IOP in glaucoma

Mechanism of Action

Prostaglandin FP receptor stimulation promotes aqueous humor outflow via uveoscleral pathway.

Side Effects

Brown pigmentation of iris; darkening of eyelid; increased number, length, thickness, and darkening of eyelashes; 5%-15% experience blurred vision; itching, burning, or stinging; conjunctival hyperemia; 1%-4% experience dry eye or excessive tearing, eye pain, eyelid discomfort and/or crusting, sensitivity to light. Macular edema has occurred when administered to patients with lens injuries.

Adverse Reactions

Rare reports of retinal problems (embolus, detachment, and vitreous hemorrhage) in patients with diabetic retinopathy. Up to 4% of patients taking latanoprost reported respiratory problems. Up to 2% of patients taking latanoprost reported chest pain, musculoskeletal discomfort, and skin rashes.

h, Hour; *IOP,* intraocular pressure; *NSAID,* nonsteroidal antiinflammatory drug.

As a result, these drugs have the same action as the parasympathetic neurotransmitter acetylcholine. Pilocarpine (Isopto Carpine) is an example of a cholinergic agonist.

Cholinesterase inhibitors are indirect-acting cholinergics, which inactivate the enzyme cholinesterase that typically breaks down acetylcholine. By inhibiting enzymatic destruction of acetylcholine, more acetylcholine is available to stimulate cholinergic receptors in the eye. Echothiophate (Phospholine Iodide) is an example of a cholinesterase inhibitor. Figure 49-1, *B* and 49-1, *C* illustrate increased IOP resulting in open-angle and narrow-angle glaucoma. Table 49-5 lists the commonly prescribed ophthalmic cholinergic drugs and their dosages, uses, and considerations. Refer to Chapter 19 for more information on cholinergic drugs.

Beta-Adrenergic Blockers

Beta-adrenergic blockers, also known as beta blockers, are one of the first-line drugs used in the treatment of glaucoma. Beta-adrenergic blockers decrease IOP by decreasing the production of aqueous humor. Examples of ophthalmic beta-adrenergic blockers include betaxolol (Betoptic), carteolol, levobunolol (Betagan), metipranolol (OptiPranolol), and timolol (Timoptic).

Side Effects and Adverse Effects

In the eye, beta-adrenergic blockers (see Table 49-5) may cause some eye discomfort, which is possible with most eye medications. Some types cause miosis. Because the pupil does

TABLE 49-5 CHOLINERGICS AND BETA-ADRENERGIC BLOCKERS

GENERIC (BRAND)	ROUTE AND DOSAGE (TO AFFECTED EYE[S])	USES AND CONSIDERATIONS
Direct-Acting Cholinergics		
pilocarpine HCl (Isopto Carpine, Pilopine HS)	A/C: Sol: 1%-2%, 1 gtt, up to q.i.d. Gel: Apply ½-in ribbon in lower eyelid h.s.	Decreases IOP in both open-angle and acute angle-closure glaucoma; prevents postoperative IOP elevation. Miosis decreases vision in darkened environments. Retinal detachment may occur in patients with preexisting retinal disease. May worsen preexisting iritis. Pregnancy category: C
Indirect-Acting Cholinesterase Inhibitors		
echothiophate iodide (Phospholine Iodide)	A: Sol 0.03%-0.25%: 1 gt 1-2 times/d	Decreases IOP in chronic open-angle glaucoma and chronic angle-closure glaucoma after cataract and glaucoma surgery. Miosis decreases vision in darkened environments. May have additive effects in patients with myasthenia gravis who take systemic cholinesterase inhibitors. May cause retinal detachment, iris cysts, and lens opacities. Pregnancy category: C
Beta-Adrenergic Blockers		
betaxolol HCl (Betoptic S)	A: Susp 0.25% or sol 0.5%: Usual dose 1-2 gtts b.i.d.	Decreases IOP in chronic open-angle glaucoma and ocular hypertension. Does not produce miosis like some beta blockers. Relatively contraindicated in patients with asthma, bradycardia, and HF due to systemic effects of beta blockers if absorbed. May have additive effect in patients receiving oral beta blockers. Wait 15 minutes after administration before inserting contact lenses. Pregnancy category: C
carteolol HCl	A: Sol 1%: 1 gtt b.i.d.	Decreases IOP in chronic open-angle glaucoma and ocular hypertension. Less effective in narrow angle glaucoma. Relatively contraindicated in patients with asthma, bradycardia, and HF. May have additive effect in patients receiving oral beta blockers. Miosis decreases night vision. Wait 15 minutes after administration before inserting contact lenses. Pregnancy category: C
levobunolol HCl (Betagan Liquifilm)	A: Instill 1-2 drops of the 0.25% solution into each affected eye b.i.d., or instill 1-2 drops of the 0.5% solution into each affected eye once daily. A dosage greater than 1 drop of the 0.5% preparation b.i.d. generally does not further reduce intraocular pressure (IOP) and is not recommended	Decreases IOP regardless of glaucoma. Decreased miotic effect. Relatively contraindicated in patients with asthma, bradycardia, and HF. May have an additive effect in patients receiving oral beta blockers. Wait 15 minutes after administration before inserting contact lenses. Pregnancy category: C
timolol maleate (Timoptic)	A: Sol 0.25%-0.5%: Initially: 1 gt b.i.d.; maint: 1 gt/d once response occurs with initial dosage	Decreases IOP in chronic open-angle glaucoma and ocular hypertension. Relatively contraindicated in patients with asthma, bradycardia, and HF. May have additive effect in patients receiving oral beta blockers. Wait 15 minutes after administration before inserting contact lenses. Pregnancy category: C

A, Adult; *b.i.d.,* twice a day; *C,* child; *d,* day; *gt,* drop; *gtt,* drops; *HF,* heart failure; *IOP,* intraocular pressure; *maint,* maintenance; *NA,* not applicable; *oint,* ointment; *PB,* protein-binding; *q.i.d.,* four times a day; *sol,* solution; *susp,* suspension; *t½,* half-life; *t.i.d.,* three times a day; *wk,* week.

not dilate adequately in dark environments, patients taking these drugs may experience vision problems at night.

While ophthalmic drugs do not typically enter the general circulation in large amounts, it can occur to the extent that systemic effects occur. Beta-adrenergic blockers can slow the heart rate, which can worsen bradycardia, AV heart block, and heart failure. Also, these drugs can prevent adequate bronchodilation in patients who have asthma and other obstructive pulmonary diseases. Refer to Chapter 18 for more information on adrenergic blockers.

Alpha-Adrenergic Agonists

Alpha-adrenergic agonists decrease IOP by decreasing production and improving outflow of aqueous humor. Examples include apraclonidine (Iopidine), brimonidine (Alphagan), epinephrine, and dipivefrin, a prodrug of epinephrine.

Side Effects and Adverse Effects

The most common effects of topical administration are burning, stinging, blurred vision, and headache. Epinephrine and dipivefrin cause adverse cardiovascular effects such as tachycardia and hypertension; these are less common with dipivefrin. Patients with narrow-angle glaucoma should not take epinephrine and dipivefrin because dilation of the pupil may allow the iris to block the outflow of aqueous humor, triggering acute closed-angle glaucoma. Apraclonidine and brimonidine, on the other hand, are selective alpha$_2$ agonists that decrease IOP without causing mydriasis or adverse cardiovascular effects. Because of the relative safety of alpha$_2$ adrenergic agonists, they are often used when ophthalmic beta-adrenergic antagonists are contraindicated.

Carbonic Anhydrase Inhibitors

Carbonic anhydrase inhibitors (CAIs) decrease IOP by decreasing the production of aqueous humor. These drugs, initially developed as diuretics, are sometimes used for adjunctive treatment of glaucoma. They are indicated for both open-angle and acute closed-angle glaucoma. Carbonic anhydrase inhibitors are not as effective as other antiglaucoma drugs, though, and they carry a greater risk of adverse effects. For these reasons, they are generally added to a therapeutic regimen only after other treatment options have been exhausted. Both topical and systemic formulations are available. Examples of topical carbonic anhydrase inhibitors are brinzolamide (Azopt) and dorzolamide (Trusopt). Acetazolamide (Diamox) and methazolamide are systemic forms. Table 49-6 presents additional information on these drugs.

Side Effects and Adverse Reactions. Adverse effects of carbonic anhydrase inhibitors, particularly for the systemic forms, include CNS effects such as lethargy, drowsiness, headache, seizures, paresthesias, and mental status changes. GI effects such as nausea, vomiting, diarrhea, altered taste, and anorexia may occur. Because they have diuretic effects, polyuria and increased thirst are common, and fluid and electrolyte disturbances may occur as a result. They may promote hyperuricemia, which may precipitate gout attacks. They may also worsen liver disease, resulting in hepatic encephalopathy and even hepatic necrosis. Because they are sulfonamides, they should not be given to patients who have experienced allergic reactions to other sulfonamide drugs.

Osmotics

Osmotics are generally used preoperatively and postoperatively to decrease vitreous humor volume, reducing IOP. These drugs are primarily used in the emergency treatment of acute closed-angle glaucoma because of their ability to rapidly reduce IOP. Commonly prescribed osmotic drugs are presented in Table 49-7.

Side Effects and Adverse Reactions. Osmotic medications can cause headache, nausea, vomiting, and diarrhea. Disorientation resulting from electrolyte imbalances can result from use of mannitol and urea, especially in older adults.

Nursing Process
Patient-Centered Collaborative Care

Antiglaucoma Drugs

Assessment

- Obtain a thorough medical history.
- Obtain a thorough drug history, including allergies and use of herbal preparations and recreational drugs.
- Check baseline vital signs for future comparison.
- Check baseline visual acuity.
- Obtain, or assist with obtaining, baseline IOP measurements.

TABLE 49-6 CARBONIC ANHYDRASE INHIBITORS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
acetazolamide (Diamox)	A: PO: 250-1000 mg/d in divided doses for amounts >250 mg; doses >1000 mg show no increased benefit	Reduces IOP in both open- and narrow-angle glaucoma. Volume loss may cause dehydration and postural hypotension. Electrolyte imbalance may occur. Pregnancy category: C
brinzolamide ophthalmic susp 1% (Azopt)	A: 1 gt t.i.d.	Topical: For elevated IOP in patients with ocular hypertension or open-angle glaucoma by suppressing production of aqueous humor. Pregnancy category: C
Cosopt (timolol/dorzolamide 0.5%/2%)	A: 1 gt 0.25% in affected eye(s) b.i.d.	Decreases aqueous production. Contraindicated with sulfa allergy. Adverse effects include asthma, bronchospasm, bradycardia, and dyspnea.
dorzolamide (Trusopt)	A: sol 2%: 1 gt t.i.d.	Do not use with oral carbonic anhydrase inhibitors. Side effects include burning, stinging, and bitter taste.

A, Adult; *b.i.d.,* two times a day; *C,* child; *d,* day; *gt,* drop; *h,* hour; *IOP,* intraocular pressure; *PB,* protein-binding; *PO,* by mouth; $t_{1/2}$, half-life; *t.i.d.,* three times a day; *UK,* unknown; *>,* greater than.

TABLE 49-7 OSMOTICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Glycerin (Osmoglyn, Ophthalgan)	Osmoglyn: A/C: PO: 1-1.8 g/kg given 1-1.5 h before surgery Ophthalgan: A: 1-2 gtt before examination of edematous cornea	Decreases volume of intraocular fluid to lower ocular tension. Carbohydrate; use with caution in patients with diabetes. Pregnancy category: C; PB: UK; t½: 30-45 min
mannitol (Osmitrol)	A: IV: sol 15%-20%, 1.5-2 g/kg over 0.5-1 h	Monitor I&O; weigh daily. Contraindicated in severe pulmonary congestion, anuria, and dehydration. Use with caution in patients with HF. Pregnancy category: C; PB: UK; t½: 15-100 min

A, Adult; *b.i.d.,* twice a day; *C,* child; *HF,* heart failure; *h,* hour; *I&O,* intake and output; *IV,* intravenous; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *sol,* solution; *t½,* half-life; *UK,* unknown.

- Assess for conditions in which antiglaucoma drugs are contraindicated or relatively contraindicated.
  - Prostaglandin analogues may worsen respiratory conditions.
  - Beta-adrenergic blockers may worsen conditions such as bradycardia, heart block, and obstructive respiratory conditions such as asthma and chronic bronchitis.
  - Alpha adrenergic agonists may worsen conditions such as narrow-angle glaucoma, tachyarrhythmias, and hypertension.
  - Cholinergic agonists and cholinesterase inhibitors may worsen conditions such as acute iritis, bradycardia or heart block, cardiac disease, and obstructive respiratory conditions such as asthma and chronic bronchitis.
  - Carbonic anhydrase inhibitors may worsen conditions such as dehydration, electrolyte imbalances, diabetes, obstructive respiratory conditions such as asthma and chronic bronchitis, bone marrow suppression, hepatic disease, and narrow-angle glaucoma.
  - Systemic hyperosmotic drugs such as mannitol may worsen conditions such as dehydration, electrolyte imbalance, pulmonary edema, heart failure, and obstructive respiratory conditions such as asthma and chronic bronchitis.

Nursing Diagnoses

- Deficient knowledge related to purpose of and administration of antiglaucoma drugs
- Disturbed sensory perception (visual) related to drug-induced visual changes
  - Prostaglandin analogues, beta-adrenergic blockers, alpha-adrenergic agonists, and cholinergic agents may cause blurred vision.
  - Beta-adrenergic blockers typically cause miosis, which impairs vision in dark environments.
  - Alpha adrenergic agonists typically cause mydriasis, which increases sensitivity to light.
  - Cholinergic agonists and cholinesterase inhibitors may cause myopia and will impair vision in dark environments.
  - Carbonic anhydrase inhibitors may cause swelling of the lens.
- Risk for injury related to impaired vision
- Risk for electrolyte imbalance secondary to carbonic anhydrase inhibitors and systemic osmotic
- Anxiety related to drug-induced visual changes

Planning

- Patient will take antiglaucoma medications in dose and times prescribed.
- Patient will demonstrate proper method of ophthalmic drug administration.
- Patient will avoid contamination of tip of tube or dropper.
- Patient's IOP will decrease to within target range.

Nursing Interventions

- Monitor for significant alterations in patient status.
  - Monitor patients taking prostaglandin analogues for blurred vision, dyspnea, and pulmonary crackles and wheeze.
  - Monitor patients taking beta-adrenergic antagonists for blurred vision, bradycardia, and pulmonary wheeze.
  - Monitor patients taking alpha-adrenergic agonist analogues for blurred vision, tachycardia, and elevated blood pressure.
  - Monitor patients taking cholinergics for blurred vision, dry mouth, bradycardia, and pulmonary wheeze.
  - Monitor patients taking carbonic anhydrase inhibitors for blurred vision, dehydration, and electrolyte imbalances, hyperglycemia, blood dyscrasias, and pulmonary wheeze.
  - Monitor patients taking systemic hyperosmotic drugs for dehydration, electrolyte imbalances, pulmonary crackles or wheeze, and peripheral edema.

Patient Teaching

General

- Advise patient to never stop medication suddenly without prior approval of health care provider.

- Advise patient to avoid driving or operating machinery while vision is impaired.
- Explain importance of follow-up appointments for subsequent ophthalmologic examination and reevaluation of intraocular pressure.
- Counsel patients with glaucoma to avoid drugs with potential to increase IOP (Table 49-8).
- If both eyedrops and eye ointment are prescribed, instruct patient to put in eyedrops first.
- If more than one kind of eyedrop is ordered, instruct patient to wait at least 5 minutes before instilling second medication.
- Refer to Chapter 13 for more information on medication administration; Box 13-1 and Figure 13-3 provide information on eyedrops, and Box 13-2 and Figure 13-4 provide information on eye ointments.

Cultural Considerations

- Depending on patient's culture, include appropriate support person in health teaching and decisions. This need is heightened in conditions with possible loss of vision or diminished vision.
- Use an interpreter as needed.
- Provide printed materials in language patient reads and speaks most easily.

Evaluation

- Evaluate patient and family knowledge of purpose and administration of medications.
- Evaluate effectiveness of drug therapy. IOP should be reduced from baseline measurements.
- Evaluate for alleviation or decrease in adverse effects after interventions targeted to unwanted effects of antiglaucoma therapy.

Anticholinergic Mydriatics and Cycloplegics

Mydriatics dilate the pupils; **cycloplegics** paralyze the muscles of accommodation. Both are used in diagnostic procedures and ophthalmic surgery. (See the Unit 5 opener for a review of the autonomic nervous system and a comprehensive discussion of anticholinergics.) Anticholinergics actively block acetylcholine from attaching to cholinergic receptors, resulting in both dilation of the pupils and paralysis of the muscles of accommodation by blocking the response of sphincter muscles that normally constrict the pupil when cholinergic receptors are stimulated. Commonly prescribed anticholinergic mydriatics and cycloplegics are presented in Table 49-9.

Side Effects and Adverse Reactions

Side effects of topical anticholinergics include xerophthalmia (dry eyes), photophobia (sensitivity to light), and blurred vision. Systemic effects, while uncommon with topical use, are typical of all anticholinergic drugs and include dry mouth, increased heart rate, and constipation. These drugs are contraindicated in patients with narrow-angle glaucoma because the paralyzed iris may block the outlet for outflow of aqueous humor (see Figure 49-1, *C*).

TABLE 49-8 DRUGS WITH THE POTENTIAL TO WORSEN GLAUCOMA

DRUG	EFFECT
acetazolamide (Diamox)	While appropriate for *acute* narrow-angle glaucoma, long-term use can worsen *chronic* narrow-angle glaucoma.
Anticholinergics	Anticholinergics cause mydriasis, which can exacerbate narrow-angle glaucoma.
Corticosteroids	Corticosteroids can reduce the outflow of aqueous humor. Steroid-induced IOP does not occur in all patients, but primarily affects those with open-angle glaucoma.
Drugs for Mental Health Disorders • Monoamine oxidase inhibitors • Phenothiazines • Serotonin-norepinephrine reuptake inhibitors • Selective serotonin reuptake inhibitors • Tricyclic antidepressants • trihexyphenidyl (Artane)	These drugs have anticholinergic properties. Anticholinergics typically cause mydriasis, which can exacerbate narrow-angle glaucoma.
Miscellaneous Drugs with Anticholinergic Properties • cyclobenzaprine (Flexeril) • First-generation antihistamines • Opthalmic, nasal, and systemic decongestants • scopolamine (Transderm Scōp) • Urinary antispasmodics	These drugs have anticholinergic properties. Anticholinergics typically cause mydriasis, which can exacerbate narrow-angle glaucoma.
Sulfonamides	These drugs can cause swelling of the lens and anterior rotation of the ciliary body, which can precipitate acute narrow-angle glaucoma.

Drugs for Macular Degeneration

Age-related macular degeneration (ARMD) is a leading cause of vision loss in those age 65 years and older. The macula is that part of the eye responsible for sharp central vision; damage to the macula blurs central vision in the affected eye. There are two forms of ARMD: (1) wet (neovascular or exudative), which progresses quite rapidly, and (2) dry (atrophic), which slowly destroys vision over a period of years.

Dry ARMD is more common. It occurs in response to the deposit of extracellular material, called *drusen,* in the macula of the eye. This is coupled with areas of atrophy in the macula. Occasionally, dry ARMD will progress to wet ARMD.

Wet ARMD is associated with the growth of abnormal blood vessels behind the retina. Leakage of fluid from these vessels collects behind the retina and shifts the macula from its normal position. Wet ARMD accounts for 10% to 15% of ARMD cases; however, it causes greater destruction and is responsible for 80% of cases in which patients suffer severe vision loss or become legally blind.

An effective drug has not been identified to treat dry ARMD, but several drugs are currently in the trial stages. Some studies suggest that antioxidants and zinc supplements may have a role in preventing or slowing progression of dry ARMD.

Pharmacologic management of wet ARMD targets vascular endothelial growth factor (VEGF), a substance that plays a role in the formation of abnormal vessels in the eye. These VEGF inhibitors are intravitreal drugs that are injected into

SAFETY: Preventing Medication Errors

Do not confuse…

- betaxolol ophthalmic (Betoptic) with timolol ophthalmic (Timoptic)
- bevacizumab (Avastin) with Avostatin
- cyclopentolate (Cyclogyl) with cyclopentolate/phenylephrine (Cyclomydril)
- loteprednol ophthalmic (Lotemax) with alosetron (Lotronex)
- ofloxacin ophthalmic (Ocuflox) with flurbiprofen ophthalmic (Ocufen)
- prednisolone ophthalmic (Pred Forte) with chlorzoxazone (Parafon Forte)
- prednisone (Deltasone) with prednisolone ophthalmic (Pred Forte)
- timolol ophthalmic (Timoptic) with atenolol (Tenormin)
- timolol/dorzolamide (Cosopt) with dorzolamide (Trusopt)
- tobramycin ophthalmic (Tobrex) with dexamethasone/tobramycin (TobraDex)
- different strengths of a solution (e.g., Isopto Carpine 1% with Isopto Carpine 2%)
- ophthalmic solutions with otic or other topical solutions of the same name (e.g., cortisporin ophthalmic solution with cortisporin otic solution)

TABLE 49-9 MYDRIATICS AND CYCLOPLEGICS

GENERIC (BRAND)	ROUTE AND DOSAGE*	USES AND CONSIDERATIONS
atropine sulfate (Atropisol, Isopto Atropine)	A: sol 1%: 1-2 gtt up to q.i.d. C: sol 0.5%: 1-2 gtt up to t.i.d. Oint 1%: Apply in lower eyelid sac up to t.i.d.	Most potent cycloplegic. For refraction, especially in children; for iritis and uveitis. Not for use with glaucoma or tachycardia. Wait 5 minutes before using other drugs. Pregnancy category: C
cyclopentolate HCl (Cyclogyl)	A: sol 0.5%-2%: 1-2 gtt; then 1 gt in 5 min C: 1-2 gtt × 1; may repeat × 1 in 5-10 min with 0.5% or 1% sol	Mydriasis and cycloplegia for eye examination. Pregnancy category: C
epinephrine HCl (Epifrin, Glaucon)	A/C: sol 0.1%-2%: 1-2 gtt 1-2 times/d	For open-angle glaucoma and during eye surgery. Discard brown or precipitate solution. Pregnancy category: C
epinephrine borate (Epinal)	Surgery: A: sol 0.5-1%: Instill 1-2 gtt three times Open-angle glaucoma: A: sol 0.5% or 1.0%: Instill 1 gt in eye b.i.d.	For treatment of open-angle glaucoma and during ocular surgery. Contraindicated in narrow-angle glaucoma. Monitor tonometer readings with long-term use. Increased pressor effects. Pregnancy category: C
homatropine hydrobromide (Isopto Homatropine)	A/C: sol 2% and 5%: 1-2 gtt q3-4h Cy: Use only 2%	Similar to atropine but faster onset and shorter duration. Mydriasis and cycloplegia for eye examination. Pregnancy category: C
phenylephrine HCl (AK-Dilate)	Mydriasis: A/C: sol 2.5% or 10%: Instill 1 gt in eye before examination Mydriasis with vasoconstriction: A/C >12 y: Instill 1 gt in eye; repeat once in 1 h PRN Cy: 2.5% sol: Instill 1 gt in eye; repeat once in 1 h PRN	For eye examination or surgery and treatment of wide-angle glaucoma and uveitis. Pregnancy category: C
scopolamine hydrobromide (Isopto Hyoscine)	A: sol 0.25%: 1-2 gtt 1 h before examination; 1-2 gtt for treatment up to q.i.d.	Used for patients sensitive to atropine sulfate. More rapid onset and shorter duration than atropine. Pregnancy category: C
tropicamide (Mydriacyl Ophthalmic)	Refraction: A: 1%: 1-2 gtt; repeat in 5 min Fundus examination: 0.5%: 1-2 gtt 15-20 min before examination	Mydriasis and cycloplegia for eye examination. Pregnancy category: C

*To minimize systemic absorption, apply gentle pressure to the lacrimal duct.

A, Adult; *b.i.d.*, twice a day; *C*, child; *Cy*, cycloplegic; *gt*, drop; *gtt*, drops; *h*, hour; *IOP*, intraocular pressure; *min*, minute; *oint*, ointment; *PB*, protein-binding; *PRN*, as needed; *q.i.d.*, four times a day; *sol*, solution; $t_{1/2}$, half-life; *t.i.d.*, three times a day; *NA*, not applicable; *UK*, unknown; *y*, year; >, greater than.

the eye by ophthalmologists; trials to evaluate topical agents are in progress. Examples of VEGF inhibitors are ranibizumab (Lucentis), bevacizumab (Avastin), pegaptanib (Macugen), and aflibercept (Eylea).

Administration of Eyedrops and Ointments

Techniques for administering eyedrops and ophthalmic ointments are described in Chapter 13. Patients who wear contact lenses should be knowledgeable about the products associated with the lenses.

Patients with Eye Disorders: General Suggestions for Teaching

- Listen to patient concerns. Eye disorders carrying the possibility of blindness promote high anxiety in patients.
- Provide patient education regarding expected drug effect, dosage, side effects, and when to notify the health care provider.
- Use lay terms rather than medical terminology when providing education.
- Provide written instructions for confused or forgetful patients.
- When developing patient education materials, write them at a fifth- to eighth-grade reading level. Use a large, easily-read font. Give instructions in patient's native language.
- Supplement written instructions with images or pictograms to clarify instructions.
- Instruct patient or family member that one drop of eye medication is the preferred amount with prescriptions written for one to two drops; the conjunctival sac of the lower lid typically holds the volume of one drop without overflowing. The second drop may cause overflow, greater chance of systemic toxicity, and increased cost of treatment.
- If a second topical medication is ordered to be given at the same time, instruct patient to wait at least 5 minutes before instilling the second medication.
- Instruct patient or family member on proper administration of eyedrops or ointment. Teach them how to maintain sterile technique and prevent dropper contamination.
- Ask patient for a return demonstration of any procedure to ensure patient's ability to carry it out properly and to determine if additional teaching is needed.
- Advise patient to apply ointments at bedtime, if possible, to avoid safety problems from diminished vision that occurs from looking through the film it places over the eye.
- Instruct patient to store the drug away from heat.
- Counsel patient not to stop medication suddenly without prior approval from the prescribing health care provider.
- Advise patient to check labels on OTC drugs with a pharmacist.
- Instruct patient to carry an identification card or wear a MedicAlert bracelet at all times if allergic to any medications.
- Encourage patient to keep health care appointments. Recommend that patient bring a list of questions about their condition or medications.
- Tailor instructions for patients who wear contact lenses. Notify them regarding any special procedures that need to be done regarding use of contact lenses and the various ophthalmic medications. Advise patients to avoid wearing contact lenses in the presence of eye infections.

DRUGS FOR DISORDERS OF THE EAR

Antiinfectives

Common ear conditions requiring antibacterial drugs are acute otitis media (AOM) and acute otitis externa, commonly known as *swimmer's ear.* AOM occurs more often in children. *Streptococcus pneumoniae* is the most common pathogen, followed by *haemophilus influenzae* and *moraxella catarralis*. AOM may also be caused by other microorganisms, such as viruses.

Risk factors for the development of AOM include age younger than 2 years, attending day care centers, and exposure to tobacco smoke and air pollution. A significant decline in AOM has occurred since the pneumococcal conjugate vaccine (PCV) was introduced in 2000. Because it provides immunization against *S. pneumoniae*, families should be urged to have children receive the scheduled PCV13 as a prophylactic measure against AOM, as well as against the other more serious conditions that this vaccine prevents.

Amoxicillin is usually the drug of choice when antibiotics are indicated for AOM. The recommended dose is 40 to 45 mg/kg twice daily for 5 to 10 days depending on severity of condition and age of patient. Azithromycin and clarithromycin are often ordered if the patient has a severe allergy to penicillin. For more mild penicillin allergies, a cephalosporin may be ordered; however, the nurse should be alert to any signs or symptoms of penicillin-cephalosporin cross-sensitivity.

Otitis externa (OE) is an infection of the external auditory canal (EAC) that occurs when excess moisture and breaks in skin allow bacteria or fungi to invade the tissues. *Pseudomonas aeruginosa* and *Staphylococcus aureus* are the pathogens most often responsible. Treatment is usually with topical antibacterial or antifungal drugs, depending on the source of the infection. These are often prescribed as a combination product containing an antiinflammatory drug. An analgesic may also be needed.

If the EAC becomes so swollen that eardrops cannot reach the inner recesses of the EAC, a wick must be inserted (Figure 49-2). A wick is a thin cylinder composed of highly compressed absorbable material. It is inserted into the edematous canal, and eardrops are applied to the tip of the wick that is exposed. Sufficient drops should be administered to keep the wick moist. The wick pulls the medication down the length of the wick as it is absorbed, exposing the medication to tissues along the EAC. Wicks should be replaced every 24 to 48 hours. Once the swelling resolves, the wick will fall out, or it may be manually removed.

Topical antibacterial preparations are preferred. Oral antibiotics are required if the OE extends to the pinna.

Patency of the tympanic membrane (TM) presents a special concern when antibiotic eardrops are used. This is especially true when an edematous EAC prevents adequate visualization of the TM. Topical antibiotics such as neomycin-polymyxin B-hydrocortisone are very effective in treating OE because polymyxin B is effective against *P. aeruginosa* and neomycin is effective against *S. aureus*. However, if this drug combination is given to a patient with a perforated TM, there is a significant risk of ototoxicity. Chloramphenicol is another drug sometimes ordered for OE but contraindicated with a perforated TM. Fluoroquinolones, on the other hand, are effective against both organisms and are safe to use when the TM is incompetent; therefore, they are usually the first drug of choice when prescribing treatment for OE. When OE is caused by the growth of fungi, restoring an acidic environment with an acidifying solution such as acetic acid is usually sufficient. A topical antifungal otic solution such as clotrimazole is typically used if the fungal infection is severe.

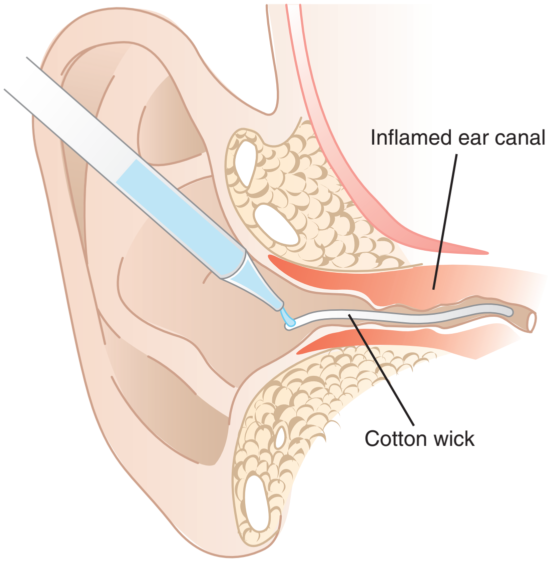

FIGURE 49–2 Ear wick inserted into an edematous canal.

Side Effects and Adverse Reactions

The most common side effect of otic antimicrobials is burning and stinging. Ototoxicity can occur with aminoglycoside antibiotics. Chloroamphenical may cause bone marrow suppression resulting in decreased erythrocytes, leukocytes, and platelets. Opportunistic overgrowth of nonsusceptible organisms may occur with any of these drugs. Hypersensitivity is a contraindication.

Table 49-10 lists selected antibacterial medications used to treat ear disorders and their dosages, uses, and considerations.

TABLE 49-10 OTIC: ANTIINFECTIVES

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Topical (Otic)		
acetic acid (Acetasol, Borofair, VoSol)	A/C >3 y: sol 2%: Insert saturated wick, keep moist × 24 h; instill 4-6 gtt q2-3h	For OE. Acidity of solution provides antibacterial and antifungal activity. May cause stinging and irritation, especially if tissues are inflamed or sloughing. Contraindicated with tympanic membrane perforation. Pregnancy category: C
chloramphenicol (Chloromycetin Otic)	A/C: Otic sol 0.5%: Instill 2-3 gtt into ear every 6-8 h	For OE. Boxed warning of bone marrow suppression after topical administration. Use restricted to serious infections that are resistant to other antimicrobials. Pregnancy category: C
Fluoroquinolones ciprofloxacin (Cetraxal, Floxin Otic) ofoxacin (Ocuflox)	A/C: Otic sol 0.2% in single-use 0.25-mL container: Instill contents into ear every 12 h for 7 d	Drug of choice for treatment of OE. Discontinue if superinfection from overgrowth of unsusceptible organisms such as fungi occurs. Pregnancy category: C
polymyxin B and neomycin	A/C: 3-4 gtt t.i.d./q.i.d. for 7-10 d	For OE. Combination product; each drug provides coverage for a different primary causative organism of OE. A corticosteroid is usually included in otic combinations. Discontinue after 10 days to prevent superinfection from fungal overgrowth. Contraindicated with tympanic membrane perforation due to an increased risk of irreversible ototoxicity. Pregnancy category: C

A, Adult; *b.i.d.,* twice a day; *C,* child; *d,* day; *GI,* gastrointestinal; *gtt,* drops; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minute; *NA,* not applicable; *OE,* otitis externa; *OTC,* over-the-counter; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *sol,* solution; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *y,* year; *>,* greater than.

Nursing Process
Patient-Centered Collaborative Care

Topical Antiinfectives: Ear Conditions

Assessment
- Obtain a medical history.
- Obtain a thorough drug history, including any allergies and use of herbal preparations and recreational drugs.
- Check vital signs. Obtain baseline data that can be compared with future findings.
- Conduct an otoscopic exam and record findings for future comparison.
- Check audiometry and tympanometry, and perform other testing as indicated.
- Assess for conditions in which selected antiinfectives are contraindicated or relatively contraindicated.

Nursing Diagnoses
- Deficient knowledge related to drug regimen (purpose, taking medications as ordered, administration of meds)
- Disturbed sensory perception (auditory) due to diagnosis
- Pain related to infection
- Risk for injury related to adverse drug effects.

Planning
- Patient will be free from ear infection after completion of drug regimen.
- Adverse effects will be minimized.

Nursing Interventions
- Complete culture and sensitivity testing, if ordered, before starting drug.
- Ensure TM patency before administering eardrops other than fluoroquinolones.
- Provide relief of associated pain, if present.
- Monitor for significant alterations in patient status
  - Monitor patients taking acetic acid solutions for burning and ear discomfort.
  - Monitor patients taking chloramphenicol for infections, increased bruising or bleeding, and pallor that could indicate bone marrow suppression. Assess for the development of superinfections.
  - Monitor patients taking fluoroquinolones for superinfections in the ear.
  - Monitor patients taking neomycin-polymyxin B-hydrocortisone for evidence of ototoxicity manifested by worsening of hearing or of alterations in balance.

Patient Teaching
- Instruct patient to complete entire course of medication (usually 10 to 14 days) and *not* to stop medication when the ear(s) feels better.
- If patient is prone to OE after swimming or showers, give instruction on prevention of OE. The Centers for Disease Control and Prevention recommends the following:
  - Keep water out of ears by using custom-fitted ear plugs.
  - If water enters the ear, tilt the ear downward to allow water to drain out. Pull the ear in different directions to enhance water drainage.
  - Use a portable hair dryer to facilitate drying.
- Instruct the patient to wear a MedicAlert bracelet at all times if allergic to medications.
- Refer to Chapter 13 for information on the administration of eardrops.

Cultural Considerations
- Depending on patient's culture, include appropriate support person in health teaching and decisions. This need is heightened in conditions with possible loss of hearing or diminished hearing.
- Use interpreter as needed.
- Provide printed materials in language patient reads and speaks most easily.

Evaluation
- Evaluate patient and family's knowledge of drug regimen.
- Determine effectiveness of drug therapy.
- Inquire regarding alleviation of side effects.

Antihistamines and Decongestants

For years, antihistamine and decongestants were thought to reduce middle-ear congestion and Eustachian tube dysfunction associated with otitis media with effusion (OME), a noninfectious collection of fluid in the middle ear. The rationale was that these drugs would reduce edema of the Eustachian tube which would promote drainage from the middle ear.

In 2006, a landmark Cochrane review of the medical literature concluded that antihistamines and decongestants were not as effective as once assumed and that the risks of adverse effects outweighed the benefits. Shortly thereafter, the American Academy of Pediatrics recommended against their use for ear conditions in young children. A 2012 report by the Agency for Healthcare Research and Quality makes the following statement regarding the use of these drugs in the management of OME: "The effects on multiple short- and long-term outcomes repeatedly demonstrated no benefit for use of these medications over placebo for treating OME. … The reviewed studies found evidence of increased side effects and harms with use of these medications." Unfortunately, many patients are not aware of these findings and may continue to take these drugs.

The importance of the nurse's role in educating patients regarding this concern cannot be overstated. Numerous

OTC antihistamine-decongestant medications are readily available to unknowing patients. Examples of antihistamines include chlorphenamine (Chlor-Trimeton), clemastine (Tavist), diphenhydramine (Benadryl), and many others. Examples of decongestants are phenylephrine (Neo-Synephrine) and pseudoephedrine (Sudafed). (Pseudoephedrine requires a prescription in some states.) Of even greater concern is that most of these are available as combination products that contain both an antihistamine and decongestant. (Refer to Chapter 40 for a discussion of upper respiratory agents.)

Ceruminolytics

Cerumen (earwax) is produced by glands in the outer half of the EAC. Usually it moves to the external os by itself and is washed away; however, sometimes cerumen accumulates due to overproduction or narrowing of the EAC. In these instances, cerumen can harden in the EAC, creating a cerumen impaction.

Ceruminolytics are topical otic agents that soften or break up the cerumen so that it can be removed. They are usually composed of mineral oil with hydrogen peroxide. An example is carbamide peroxide (Auro Ear Drops, Debrox), which is available OTC. Patients may also elect to use regular mineral oil to soften the wax or prevent cerumen impaction. Generally two to five drops applied twice a day for 4 days is sufficient.

Administration of Ear Medications

Ear medications are usually contained in a liquid vehicle for ease of administration. Guidelines for the administration of eardrops are given in Chapter 13.

Irrigation

Sometimes ceruminolytics alone are insufficient. In these instances, ear irrigation can be used to flush the cerumen deposits out of the ear canal. Irrigation is best accomplished when there is direct visualization of the tympanic membrane (TM). It must be done *gently* to avoid damage to the TM. It is also important to warm the water to prevent nausea and vomiting.

Frequently used irrigating solutions include hydrogen peroxide 3% in a 1:1 solution with warm water, normal saline solution, or acetic acid (vinegar) solution mixed with warm water. Contraindications to irrigation include perforation of the IM and prior hypersensitivity.

Patients with Ear Disorders: General Suggestions for Teaching

- Instruct patient not to insert any foreign objects into the ear canal.
- Instruct patient to keep drug away from heat.
- Provide education regarding the expected drug effect, dosage, side effects, and when to notify health care provider.
- Teach patient about OTC drug concerns, particularly antihistamines and decongestants. OTC drugs may interact with prescribed drug and may have risks that outweigh any drug benefit.
- Advise patient to contact health care provider before using OTC drugs or herbal preparations to treat ear disorders.
- Encourage patient to keep follow-up appointments.

CRITICAL THINKING CASE STUDY

MH, a 70-year-old woman with POAG, is prescribed one drop of latanoprost (Xalatan) 0.005% ophthalmic solution each evening and one drop of timolol (Timoptic) 0.25% ophthalmic solution each morning and evening.

1. What is the purpose of giving two different medications to manage MH's glaucoma?
2. What special concerns related to medication timing are important for MH to consider when administering the evening dose of these medications?
3. Although systemic absorption of ophthalmic beta-adrenergic antagonists is usually small, it may potentially create problems for patients with certain conditions. Which conditions create a risk, and how will the nurse monitor for complications?
4. After a few months on these medications, MH notices changes in the appearance of her eyes. Describe the changes that MH is likely experiencing, and explain which drug is responsible.

NCLEX STUDY QUESTIONS

1. The ophthalmologist prescribes mannitol 20% to be administered IV at a dose of 1.5 g/kg to a patient with acute narrow-angle glaucoma who is awaiting surgery. Before administration, the nurse will assess the patient for which condition?
   a. Dehydration
   b. Constipation
   c. Gastrointestinal bleeding
   d. Allergies to sulfonamides
2. A patient is taking oral acetazolamide, a carbonic anhydrase inhibitor to decrease intraocular pressure. When providing drug education, what will the nurse advise the patient to anticipate?
   a. Increased weight
   b. Light sensitivity
   c. Burning or stinging of the eyes
   d. Increased urine output
3. The camp nurse is reviewing the shopping list of supplies needed for the upcoming camping season. Which product will the nurse purchase to prevent and treat cerumen impaction?
   a. Hydrogen peroxide
   b. Rubbing alcohol
   c. Charcoal
   d. Clove oil
4. A patient is about to undergo a diagnostic eye exam. The ophthalmologist asks the nurse to prepare to assist in the administration of tetracaine (Pontocaine), fluorescein stain (Fluorescite), and atropine (Isopto Atropine). Before assisting in the procedure, it is most important for the nurse to inform the ophthalmologist if the patient has a history of which condition?
   a. Cataracts
   b. Narrow-angle glaucoma
   c. Open-angle glaucoma
   d. Macular degeneration
5. The nurse has a patient demonstrate self-administration of eyedrops. Place the steps in the order in which the patient will perform them.
   a. Pull the lower lid away from the eye so that a pouch is formed.
   b. Gently shake the bottle to evenly distribute the drug.
   c. Press a finger against the inner corner of the eye for 2 to 3 minutes.
   d. Remove the cap.
   e. Tilt the head backward, and look upward.
   f. Place the dropper just above the pouch without touching the tip to the eye or finger.
   g. Wash hands.
   h. Gently squeeze one drop of medicine into the pouch.
6. When collecting a medication history from a patient with primary open angle glaucoma, the nurse identifies several drugs that could exacerbate glaucoma. Which drug poses a priority concern for this particular patient?
   a. cyclobenzaprine (Flexeril), an antispasmodic
   b. oxymetazoline (Afrin nasal spray), a decongestant
   c. prednisone (Deltasone), a corticosteroid
   d. sulfamethoxasole with trimethoprim (Bactrim), a sulfonamide antibiotic combination
7. The nurse asks a parent to demonstrate administration of eardrops on a toddler. Which steps by the parent indicate the need for additional education? (Select all that apply.)
   a. Position with the affected ear upward.
   b. Pull the ear backward and upward.
   c. Instill one drop of medication at a time allowing 3 to 5 minutes between each drop.
   d. Apply gentle pressure to the flap (tragus) over the ear canal.
   e. Keep the ear positioned upward for 5 minutes.

OBJECTIVES

- Differentiate acne vulgaris, psoriasis, drug-induced dermatitis, and contact dermatitis.
- Describe nonpharmacologic measures used to treat mild acne vulgaris.
- Describe at least three drugs that can cause drug-induced dermatitis and their characteristic symptoms.
- Compare the topical antibacterial agents used to prevent and treat burn tissue infection.
- Discuss the nursing process, including teaching, related to commonly used drugs for acne vulgaris, psoriasis, and burns.

papules, p. 727
plaques, p. 728
psoriasis, p. 731
tinea capitis, p. 727
tinea pedis, p. 727
vesicles, p. 728

Numerous skin lesions and eruptions require mild to aggressive drug therapy. Some skin disorders include acne vulgaris, psoriasis, eczema dermatitis, contact dermatitis, drug-induced dermatitis, and burn infection. Skin eruptions may result from viral infections (e.g., herpes simplex, herpes zoster), fungal infections (e.g., **tinea pedis** [athlete's foot], **tinea capitis** [ringworm]), and bacterial infections.

Most treatments for skin eruptions include topical creams, ointments, pastes, gels, lotions, and solutions. Skin lesions may appear as **macules** (flat with varying colors), **papules** (raised, palpable, and less than 1 cm in diameter), **vesicles** (raised, filled with fluid, and less than 1 cm in diameter), or **plaques** (hard, rough, raised, and flat on top). Selected skin disorders and their drug therapy regimens are discussed separately.

ACNE VULGARIS

Acne is the most common skin disorder in the United States. **Acne vulgaris** is the formation of papules, nodules, and cysts on the face, neck, shoulders, and back resulting from keratin plugs at the base of the pilosebaceous oil glands near the hair follicles. Of persons with acne, 90% are adolescents. The increase in androgen production that occurs during adolescence increases the production of sebum, an oily skin lubricant. The sebum combines with keratin to form a plug, which results in acne. Table 50-1 lists the drugs commonly used to control acne vulgaris and their dosages, uses, and considerations.

Nonpharmacologic Approach

Nonpharmacologic measures should be tried before drug therapy is initiated. A prescribed or suggested cleansing agent is necessary for all types of acne. The skin should be gently cleansed several times a day; vigorous scrubbing should be avoided. A well-balanced diet is indicated. Decreasing emotional stress and increasing emotional support are suggested. If drug therapy is necessary, nonpharmacologic measures should be maintained as well.

Topical Antiacne Drugs

Mild acne may require gentle cleansing and the use of keratolytics (keratin dissolvers such as benzoyl peroxide, resorcinol, and salicylic acid). Benzoyl peroxide is applied as a cream, lotion, or gel once or twice a day. This agent loosens the outer horny layer of the epidermis.

Tretinoin (Retin-A, Renova), a derivative of vitamin A, is a topical drug for mild to moderate acne that alters keratinization. Other antiacne agents, such as adapalene (Differin), azelaic acid (Azelex), and tazarotene (Tazorac), are used to treat mild to moderate acne. Adapalene is similar in action to tretinoin. It has antiinflammatory and comedolytic (eliminates blackheads) properties and tends to be more effective than tretinoin in reducing the number of acne lesions. Adapalene should not be used before or after extended sun exposure or sunburn. It can increase the risk of sunburn and intensify existing sunburn. Azelaic acid is as effective as benzoyl peroxide and tretinoin. Adapalene and azelaic acid can cause burning, pruritus, and erythema after several applications; however, this is less common with azelaic acid. Adapalene and tazarotene bind to select retinoid receptors; thus fewer adverse effects are anticipated.

Moderate acne requires a stronger concentration of benzoyl peroxide (10%), and topical antibiotics (e.g., tetracycline, erythromycin, clindamycin) may be added to the treatment regimen. Erythromycin and clindamycin are the most frequently prescribed topical antibiotics and have the fewest side effects.

Systemic Antiacne Drugs

For severe acne, oral antibiotics (doxycycline and minocycline [drugs of choice], tetracycline, erythromycin) and topical glucocorticoids may be prescribed. Pregnant patients should not take tetracycline because of possible teratogenic effects on the fetus. Once the condition is stabilized, the patient commonly progresses to the use of a topical preparation.

TABLE 50-1 DRUGS FOR ACNE VULGARIS AND PSORIASIS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Acne Vulgaris		
Systemic Preparations		
tetracycline HCl	A/C: >12 y: PO: Initially, 125-250 mg every 6 h for 1-2 wk (or 250-500 mg b.i.d)., then decrease slowly to 125-500 mg/d or q.o.d.	For moderate to severe acne. Inexpensive. Contraindicated during pregnancy. Take 1 h before or 2 h after meals. Do not take with milk products or antacids. Pregnancy category: D; PB: 65%; t½: 6-12 h
erythromycin (Ery-Tab)	A: PO: 250 mg q.i.d. Topical dosage: Apply 1.5% or 2% solution, 2% gel, or 2% ointment to affected area b.i.d.	For moderate to severe acne. Substitute for tetracycline. Pregnancy category: B; PB: 73%-81%; t½: 1.5-2 h
minocycline HCl (Solodyn)	A: PO: ER: 1 mg/kg once daily	Once-daily treatment for nonnodular moderate to severe acne. Take with food to decrease esophageal irritation. Do not cut/crush/chew/tabs Pregnancy category: D; PB: >90%; t½: UK.
doxycycline (Adoxa)	A: PO: 100 mg/d; start 100 mg every 12 h for 1 d	For treatment of mild to moderate acne. Adjunct treatment for severe acne. Pregnancy category: D; PB: 90%; t½: 15-24 h
isotretinoin (Amnesteem, Claravis, Sotret, Absorica)	A: PO: 0.5-1 mg/kg/d in 2 divided doses. Treat for 15-20 wk or less if nodule count reduced by >70%; *max:* 2 mg/kg/d. Take with meals. May repeat course PRN after at least 2 mo of being drug free.	For severe acne. Decreases sebum secretion. Used when oral antibiotics have failed. Avoid sunlight, contact lenses, and use with tetracycline and vitamin A to reduce toxic effects. Monitor CBC, glucose, and lipid levels. Swallow whole tab. Pregnancy category: X; PB: 99%; t½: 10-20 h

TABLE 50-1 DRUGS FOR ACNE VULGARIS AND PSORIASIS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Topical Preparations		
Keratolytic Agents		
azelaic acid (Azelex)	A/C: >12 y: Topical: cream 20%; apply b.i.d.	For mild to moderate acne. Inhibits hyperactivity of normal melanocytes. Mild pruritus, erythema, dryness, and peeling of skin might result. Pregnancy category: B; PB: UK; t½: 12 h
benzoyl-peroxide (Benzac, Persa-Gel)	A/C: 2.5%-10% 1-4 times/d (cream, gel, or lotion)	For mild to moderate acne. Promotes **keratolysis** (removal of horny layer of epidermis). May cause skin irritation (burning, blistering, swelling).
salicylic acid (Sebulex)	Antiacne/antiseborrheic: A/C: 2%-6% cream, gel, and shampoo. Use as directed.	For mild to moderate acne; promotes desquamation.
resorcinol (Bicozene)	A/C: 1%-10% cream, ointment, lotion, and shampoo	For mild to moderate acne.
resorcinol and sulfur	A/C: 2% resorcinol + 5% sulfur A/C: 2% resorcinol + 8% sulfur Use as directed.	For mild to moderate acne.
Antibiotics: Topical		
tetracycline	Ointment: 3% Sol: 2.2 mg/mL Use as directed	For moderate acne. Pregnancy category: B; PB: N/A; t½: N/A
erythromycin	Ointment: 2% Gel: 1.5%-2% Use as directed	For moderate acne. Pregnancy category: B; PB: N/A; t½: N/A
clindamycin (Cleocin)	Gel: 1/5 Lotion: 1% Sol: 1% Use as directed	For moderate acne. Pregnancy category: B; PB: N/A; t½: N/A
Topical Vitamin A Derivatives		
tretinoin (Retin-A)	Cream: 0.0.25%-0.1% Gel: 0.025%-0.1% Apply h.s.	For mild to moderate acne. Vitamin A derivative. May be used with benzoyl peroxide or topical antibiotic. Do not apply to open wounds. Cleanse area first. Pregnancy category: B; PB: UK; t½: UK
adapalene (Differin)	A/C: >12 y: topical: 0.1% creme, gel, or lotion; 0.3% gel apply after washing h.s.	For mild to moderate acne. Do not use before or after extended sun exposure (it intensifies sunburn). Pruritus may occur. Pregnancy category: C; PB: UK; t½: UK
adapalene 0.1% + benzoyl peroxide 2.5% gel (Epiduo)	A: After washing, apply thin film to affected areas of face and/or trunk daily. Decrease frequency or discontinue if severe irritation occurs C: Not recommended	For acne vulgaris in patients >12 years. Pregnancy category: C; PB: N/A; t½: N/A
Oral Contraceptives		
Estrostep	A: PO: 1 tab/d for 21 d; no tab for 7 d; Take as OC schedule	FDA approved for treatment of acne. Pregnancy category: X; PB: N/A; t½: 5-14 h with norethindione; 26 h with ethinyl estradiol
Ortho Tri-Cyclen	A: PO: 1 tab/d for 21 d; then no tab for 7 d; take as OC schedule	FDA approved for treatment of acne. Pregnancy category: X; PB: N/A; t½: 12-30 h with deacetyl norgestimate; 26 h with ethinyl estradiol
Drospirenone/ ethinylestradiol (Yaz, and others)	A: PO: 3 mg/0.02 mg, 1 active tab daily for 24 d, then 1 inert tab daily for 4 d	To treat moderate acne in female patients ≥14 y. Take at same time each day.
Psoriasis		
methoxsalen (Oxsoralen, 8MOP, Oxsoralen Ultra, Uvadex)	A: PO: 10-70 mg (according to body weight) 2 h before exposure to therapeutic ultraviolet rays. Topical application before exposure to ultraviolet rays.	For severe psoriasis. Systemic antimetabolite. Avoid during pregnancy. Avoid sunlight during drug therapy; sunlight could cause burning and blistering. Pregnancy category: C/D; PB: 80%-90%; t½: >2 h

Continued

TABLE 50-1 DRUGS FOR ACNE VULGARIS AND PSORIASIS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
acitretin (Soriatane)	A: PO: Initial: 25-50 mg once daily with main meal. Maintenance doses of 25-50 mg/d may be given, dependent upon person's response to initial treatment. Trials found that 25 mg/d for Rx of psoriasis vulgaris are similar in efficacy to 50 mg/d with fewer and less severe adverse clinical and laboratory events.	For recalcitrant psoriasis, including plaque, guttate, erythrodermic, palmar-plantar and pustular types. May take up to 6 mo for response to treatment. Pregnancy category: X; PB: 99%; t½: 4-8 d
Topical Preparations		
anthralin (Psoriatec)	A: Topical: 1.0%-1.2% cream	For moderate psoriasis. Inhibits DNA synthesis thus suppressing proliferation of epidermal cells. May stain clothing, skin, and hair.
calcipotriene (Dovonex)	A: Topical: cream, ointment, and scalp sol: 0.005%; apply daily or b.i.d.	For mild to moderate plaque psoriasis. Burning, stinging, and erythema may occur. Excess use may increase serum calcium level. Pregnancy category: C; PB: UK; t½: UK
calcipotriol/betamethasone dipropionate (Taclonex)	Psoriatic plaque: A: Topical: ointment; apply once daily to affected areas for up to 4 wk; *max:* 100g/wk	First once-daily topical ointment
clobetasol propionate (Clobex)	A: Lotion: Apply thin layer b.i.d.; *max:* 50 g/wk Spray: Spray on b.i.d., rub in gently and completely; *max:* 50g/wk for 4 consecutive wk; avoid occlusion in both forms. Neither product recommended for children <18 y	Super-high-potency corticosteroid for moderate to severe plaque psoriasis of <20% BSA. Adverse effects include reversible hypothalamic-pituitary-adrenal axis suppression and local site burning. Reassess lesions after 2 weeks of treatment. Contraindicated for application to axilla, face, or groin. Pregnancy category: C
coal tar (Scytera)	A: Topical: shampoo, paste, soap, ointment, lotion, solution, foam	For mild to moderate psoriasis. Suppresses DNA synthesis, decreasing mitotic activity. May stain clothing, skin, and hair.
tazarotene (Tazorac)	A: Topical: 0.05% and 0.1% gel. Apply in evening to lesions. Indicated for up to 20% BSA.	For mild to moderate psoriasis; can also be used for acne. Reduces epidermal inflammation. Photosensitivity can occur.
Biologic Agents		
alefacept (Amevive)	A: IM: 15 mg q1wk for 12 weeks	For severe chronic plaque psoriasis. Inhibits T-cell activation. Pregnancy category: B; PB: UK; t½: 270 h
adalimumab (Humira)	Moderate to severe psoriasis: A: subQ: 40 mg q other wk Start 80 mg subQ for 1 wk on wk 0; then 40 mg subQ q2wk on wk 1. Psoriasis arthritis: A: 40 mg subQ q2wk	Human IgG1 monoclonal TNF-alpha antibody. Pregnancy category: B; PB: UK; t½: 10-20 d
etanercept (Enbrel)	A: subQ: Psoriatic arthritis: 50 mg b.i.w. Psoriasis: Start with 50 mg b.i.w. for 3 mo; then 50 mg/wk	For moderate to severe psoriasis. Pregnancy category: B; PB: UK; t½: 115 h
infliximab (Remicade)	A: IV: Psoriasis: 5 mg/kg IV infusion (>120 min) weeks 0, 2, 6, then q8wk	FDA approved in 1999 for treatment of psoriasis Pregnancy category: C; PB: UK; t½: 9.5 d
ustekinumab (Stelara)	A: >18 y: <100 kg: 45 mg subQ once, then 4 wk later, and then once q12wk. >100 kg: 90 mg subQ once, then 4 wk later, and then once q12wk. C: Not recommended for children <18 y	For moderate to severe plaque psoriasis. May affect CYP450 substrates. Pregnancy category: B.
Keratolytic Agents		
salicylic acid, sulfur, resorcinol		See acne vulgaris.

Isotretinoin (Amnesteem) is used for treatment of severe cystic acne. It can be administered orally or topically. It decreases sebum formation and secretion and has antiinflammatory and antikeratinizing (keratolytic) effects. The typical patient takes this drug for 4 to 6 months. It can cause adverse reactions such as chelitis (90%), dizziness, conjunctivitis, skin irritation, pruritus, epistaxis, hirsutism, and photosensitivity. Isotretinoin must not be used during pregnancy because of teratogenic effects. Using vitamin A or tetracycline with isotretinoin may increase its adverse effects. Baseline blood tests are required before initiating isotretinoin therapy and at intervals throughout therapy. Additional cautions associated with isotretinoin include the following: Do not breastfeed, give blood during or for 1 month after therapy, take other medications or herbal products without first consulting the health care provider, drive at night without knowing the effect of isotretinoin on night vision, or have cosmetic procedures to smooth skin. Instruct the patient to avoid excessively vigorous activity and to contact the health care provider and stop taking isotretinoin if experiencing muscle weakness, which may be an indication of serious muscle damage. Monitoring of complete blood count (CBC), glucose and lipid levels, and urinalysis on a regular basis is important. Isotretinoin must not be used during pregnancy; its pregnancy category is X. Because of this drug's powerful teratogenicity, a risk-management system to prevent isotretinoin-related teratogenicity was designed by the FDA Dermatologic and Ophthalmic Advisory Committee in 2002. Named the System to Manage Accutane-Related Teratogenicity (SMART), its purpose was to ensure that no patient is pregnant when treatment is initiated and no patient becomes pregnant while taking the drug or for at least 1 month after completing a course of isotretinoin. The iPLEDGE program replaced SMART in December 2005. An Internet-based registry system, iPLEDGE uses a central database to track isotretinoin users and account for all information and access to the drug. This comprehensive program has rules for the health care provider, patient, pharmacist, and wholesaler, as follows:

- Female patient responsibilities: Female patients must receive warnings of teratogenicity both orally and in writing before use. Two negative pregnancy tests are required before starting the drug, and one negative test is required before each monthly refill. Two effective methods of contraception are required 1 month before, throughout, and 1 month after isotretinoin treatment. (Exceptions are total abstinence from intercourse or following hysterectomy.) Patients must review iPLEDGE educational materials on a variety of topics, including reasons for contraception when using a drug known to be teratogenic. A signed patient information/informed consent document is also required.
- Health care provider responsibilities: Registration by the health care provider for the iPLEDGE program is required, and the patient must follow up by telephone or Internet before treatment, monthly during treatment, and 1 month after treatment. During these contacts, the patient must indicate both birth control methods and respond to questions related to program requirements. After registering and agreeing to follow iPLEDGE, the health care provider must enter the two methods of birth control the patient is using and the results of monthly pregnancy tests. Initial and refill prescriptions must also be entered.
- Pharmacist responsibilities: Pharmacists must be registered with the iPLEDGE program. Isotretinoin must be obtained from a wholesaler also registered with the iPLEDGE program. The pharmacist for each prescription must get authorization from iPLEDGE, confirm with iPLEDGE that the prescription date is within 7 days, dispense a 30-day supply (maximum), and indicate the risk-management authorization number on the prescription.
- Wholesaler responsibilities: Wholesalers must be registered with the iPLEDGE program.

iPLEDGE has recently become less stringent for female patients not of childbearing age and for male patients.

PSORIASIS

Psoriasis is a chronic skin disorder that affects 2% to 4% of the U.S. population. Onset usually occurs before age 30 years, but it may occur as early as age 10 years. Psoriasis is characterized by erythematous papules and plaques covered with silvery scales. It appears on the scalp, elbows, palms of the hands, knees, and soles of the feet. With psoriasis, epidermal cell growth and epidermal turnover are accelerated to approximately five times the normal expected epidermal growth. Antipsoriatic drug therapy uses preparations such as coal tar products and anthralin to keep the psoriasis in check; however, there are usually periods of remission and exacerbation.

Topical and Systemic Preparations

Psoriatic scales may be loosened with keratolytics (salicylic acid, sulfur). Topical glucocorticoids are sometimes used for mild psoriasis. Other topical preparations for psoriasis include anthralin (Dithro-Crème Psoriatec, Zithranol-RR) and coal tar (Estar), Oxipor VHC, Balnetar, and Scytera. Applications of 1% anthralin may cause erythema to occur. This agent can stain clothing, skin, and hair. Coal tar products are available in shampoos, lotions, and creams. They have an unpleasant odor and can cause burning and stinging, so they are rarely used. A topical product for mild to moderate psoriasis is calcipotriene (Dovonex), a synthetic vitamin D_3 derivative useful for suppressing cell proliferation. This drug may cause local irritation and the serious adverse effects of hypercalciuria and hypercalcemia (increased urine and serum calcium levels). A topical antipsoriatic, tazarotene (Tazorac), is used to treat mild to moderate psoriasis. Photosensitivity is a side effect of tazarotene; therefore, the patient should use sunscreen to avoid severe sunburn.

The anticancer drug methotrexate is a systemic drug that slows high growth fraction. It is prescribed to decrease the acceleration of epidermal cell growth in severe psoriasis.

Ultraviolet A (UVA) may be used to suppress mitotic (cell division) activity. Photochemotherapy, a combination of ultraviolet radiation and the psoralen derivative methoxsalen (photosensitive drug), is used to decrease proliferation of epidermal cells. This type of therapy is called *psoralen and ultraviolet A* (PUVA). PUVA permits lower doses of methoxsalen and ultraviolet A to be given.

High-cost biologic agents are helpful in the management of psoriasis in patients who are refractory to ultraviolet B (UVB) phototherapy and need improved control. FDA-approved agents include the T-cell antagonist alefacept (Amevive) and the tumor necrosis factor (TNF) inhibitors etanercept (Enbrel), infliximab (Remicade), adalimumab (Humira), and interleukin antagonist ustekinumab (Stelara). All TNF inhibitors have a risk of severe opportunistic infection. These biologic agents are expensive but tend to have fewer side effects with comparable efficacy to other systemic treatments.

Alefacept (Amevive) is a recombinant protein that modifies the inflammatory process and inhibits the activation of memory effector T lymphocytes. No increased rate of opportunistic infections or malignancy has been observed. The drug is administered IM weekly for 12 weeks. Chills are the most common side effect. A second 12-week cycle may be initiated, but with decreased benefits from the first cycle. Weekly monitoring of CBC and T-cell counts is required, and alefacept must be discontinued if the CD4+ T-cell count falls lower than 250 cells per microliter.

Etanercept (Enbrel) is a soluble recombinant human TNF-alpha inhibitor. This agent worsens infections, especially tuberculosis (TB). A tuberculin test (PPD) is required before initiation of therapy. Etanercept may also worsen heart failure (HF). The drug is administered twice weekly for 12 weeks, and then weekly.

Infliximab (Remicade) is a monoclonal antibody that neutralizes TNF-alpha purified protein derivative (PPD). The drug is administered IV at 0, 2, and 6 weeks, and then every 8 weeks as tolerated. Opportunistic infection rate is higher than with other agents. A tuberculin test before the start and during treatment is recommended. This drug is associated with demyelinating disease. The major side effect is increased risk for infection.

Adalimumab (Humira) is a TNF-alpha inhibitor. The drug is administered subcutaneously every other week.

Table 50-1 lists the drugs used to control psoriasis.

Side Effects and Adverse Reactions

- Anthralin: Erythema (redness) to normal skin, inflamed eyes, and staining effect.
- Coal tar: Skin irritation, such as burning; photosensitivity; and staining effect.
- Methoxsalen: Nausea, headache, vertigo, rash, pruritus, and burning and peeling of skin. Adverse reactions: Anemia, leukopenia, thrombocytopenia, ulcerative stomatitis, bleeding, alopecia, and cystitis.
- Alefacept: Injection site reaction (erythema, itching, pain, swelling), dizziness, throat inflammation, nausea, muscle pain, and chills.
- Etanercept: Injection site reaction (erythema, itching, pain, swelling) and infections, including reactivation of TB.
- Infliximab: Infusion reactions and infections, including reactivation of TB.
- Adalimumab: Injection site reaction (erythema, itching, pain, swelling) and infections, including reactivation of TB.
- Ustekinumab: Nasopharyngitis, URI, headache, fatigue

VERRUCA VULGARIS (WARTS)

The common wart is a hard, horny nodule that may appear anywhere on the body, particularly on the hands and feet. Warts may be benign lesions, or they may be precursors to cancerous lesions, especially those in the genital region. They may be removed by freezing, electrodesiccation, or surgical excision. Drugs commonly used in the treatment of warts include salicylic acid and podophyllum resin. Salicylic acid promotes desquamation. It can be absorbed through the skin, and salicylism (toxicity) might occur. Podophyllum resin is indicated mainly for venereal warts and is not as effective against the common wart. This drug also can be absorbed through the skin; toxic symptoms such as peripheral neuropathy, blood dyscrasias, and kidney impairment may result if a large area is treated. Podophyllum can cause teratogenic effects and should not be used during pregnancy. Imiquimod (Aldara, Zyclara) and podofilox (Condylox) may be prescribed as alternative agents for podophyllin. Both drugs may be used for topical treatment of external genital and perianal warts.

Nursing Process

Patient-Centered Collaborative Care

Acne Vulgaris and Psoriasis

Assessment

- Obtain history from patient of the onset of skin lesions. Note whether or not there is a familial history of the disorder.
- Assess patient's skin eruptions. Describe lesions, location, and drainage, if present.
- Obtain culture of a purulent draining skin lesion.
- Determine baseline vital signs. Report any elevation in temperature.
- Assess the psychological effects of skin lesions and changes in body image.
- Assess type of psoriatic lesions (pustules, plaques, or guttate)

Nursing Diagnoses

- Deficient knowledge related to management of skin lesions and adverse effects of medications used to treat skin lesions
- Risk for impaired skin integrity related to side effects of some medications
- Risk for infection due to selected medications
- Risk for disturbed body image related to skin lesions

- Risk for situational low self-esteem related to skin lesions

Planning

- Patient will have increased knowledge of management of skin condition.
- Patient's lesions will be decreased in size or will be absent after drug therapy and skin care.
- Patient will report improved body image.

Nursing Interventions

- Establish rapport, because patient may be embarrassed.
- Apply topical medications to skin lesions using aseptic technique.
- Monitor vital signs, and report abnormal findings.
- Check lesion sites during drug therapy for improvement or adverse reactions to drug therapy.

Patient Teaching

General

- Advise patient not to use harsh cleansers. Tell patient to gently cleanse the skin several times a day.
- Teach patient to apply topical ointments and creams using clean technique.
- Inform patient about side effects and adverse reactions associated with drugs taken.
- Advise patient to report abnormal findings immediately.
- Instruct patient to notify health care provider if pregnant or if there is possibility of pregnancy. Many agents used to treat acne can cause teratogenic effects on the fetus.
- Advise patient to keep health care appointments and have laboratory tests performed as prescribed.

Self-Administration

- Teach patient and family about how to administer biologic agents given via the parenteral route (e.g., preparation and administration of Amevive: store diluted solution in refrigerator, and use within 4 hours; do not shake medication; rotate injection sites, leaving at least 1 inch between sites).

Cultural Considerations

- Respect patient's cultural beliefs and alternative methods for treating acne vulgaris or psoriasis. Plan may need modification to include pharmacologic treatment for acne or psoriasis.
- Obtain an interpreter when necessary; do not rely on family members, who may not fully disclose because of cultural norms.

Evaluation

- Evaluate patient's knowledge of management of condition.
- Evaluate effectiveness of drug therapy. If improvement is not apparent, drug therapy and skin care regimen may need to be changed.
- Be aware of the different time periods for improvement with various drug therapies.

Cantharidin (Cantharone, Verr-Canth) is used to remove the common wart; however, it can be harmful to normal skin. For treating the common wart, cantharidin is applied to the wart, allowed to dry, and then the wart is covered with nonporous tape for 24 hours. The procedure may be repeated in 1 to 2 weeks.

Many OTC agents are used to remove warts. The efficacy of some of these is questionable; however, some that contain chemical compounds such as salicylic acid may be effective.

DRUG-INDUCED DERMATITIS

An adverse reaction to drug therapy may result in skin lesions that vary from a rash, urticaria, papules, and vesicles to life-threatening skin eruptions such as erythema multiforme (red blisters over a large portion of the body), Stevens-Johnson syndrome (large blisters in the oral and anogenital mucosa, pharynx, eyes, and viscera), and toxic epidermal necrolysis (widespread detachment of the epidermis from underlying skin layers). A hypersensitive reaction to a drug is caused by the formation of sensitizing lymphocytes. If multiple drug therapy is used, the last drug given may be the cause of the hypersensitivity and skin eruptions. The usual skin reactions are a rash, which may take several hours or a day to appear, and urticaria (hives), which usually takes a few minutes to appear. Certain drugs, such as penicillin, are known to cause hypersensitivity.

Other drug-induced dermatitides include discoid lupus erythematosus and exfoliative dermatitis. Hydralazine hydrochloride (isoniazid, phenothiazines, anticonvulsants, and antidysrhythmics), such as procainamide, may cause lupus-like symptoms. If lupus symptoms occur, the drug should be discontinued. Certain antibacterials and anticonvulsants may cause exfoliative dermatitis, resulting in erythema of the skin, itching, scaling, and loss of body hair (e.g., sulfa antibiotics are one cause of toxic epidermal necrolysis).

CONTACT DERMATITIS

Contact dermatitis, also called *exogenous dermatitis,* is caused by chemical or plant irritation. Skin rash with itching, swelling, blistering, oozing, or scaling at the affected skin sites characterizes this disorder. Chemical contacts include cosmetics, cleaning products, perfume, clothing, dyes, and topical drugs. Plant contacts include poison ivy, oak, or sumac.

Nonpharmacologic measures include avoiding direct contact with the causative irritant. Protective gloves or clothing may be necessary if the chemical is associated with work;

skin that has been in contact with the irritant should be immediately cleansed. Patch testing may be needed to determine the causal factor.

Treatment may consist of wet dressings containing Burow's solution (aluminum acetate); lotions, such as calamine, that contain zinc oxide; calcium hydroxide solution; and glycerin. Calamine lotion may contain the antihistamine diphenhydramine and is used primarily for plant irritations. If itching persists, antipruritics (systemic diphenhydramine [Benadryl]) may be used. Topical Benadryl is not recommended, as it increases the risk of allergic reaction to systemic Benadryl. Topical antipruritics should not be applied to open wounds or near the eyes or genital area. Other antipruritic treatments include baths of oatmeal and application of glucocorticoid ointments, creams, or gels.

Dexamethasone (Decadron) cream, hydrocortisone ointment or cream, methylprednisolone acetate (Medrol) ointment, triamcinolone acetonide (Aristocort), and flurandrenolide (Cordran) are examples of topical glucocorticoids that aid in alleviating dermatitis. Box 50-1 lists selected topical glucocorticoids according to their potency for relieving the itching and inflammation associated with dermatitis.

A portion of topical glucocorticoids can be systemically absorbed into the circulation. The amount and rate of absorption depend on the vehicle (cream, lotion), drug concentration, drug composition, and skin area to which the glucocorticoid is applied. Absorption is greater where the skin is more permeable—the face, scalp, eyelids, neck, axilla, and genital area. Side effects and adverse reactions may occur with prolonged use of the topical drug or if the drug is continuously covered with a dressing. Prolonged use of topical glucocorticoids can cause thinning of the skin with atrophy of the epidermis and dermis and purpura from small-vessel eruptions; therefore, prolonged use is discouraged.

BOX 50-1 TOPICAL GLUCOCORTICOIDS

Super High Potency

betamethasone dipropionate, augmented 0.05%

IMPETIGO

Impetigo, a common *Staphylococcus aureus* infection of the skin, is most commonly seen in children 2 to 5 years old. Topical agents are used in the treatment of mild and moderate infection, and oral agents are used for severe infection. The two drugs of choice are mupirocin (Bactroban) and retapamulin (Altabax). With multiple lesions and ineffective topical therapy, oral antibiotics are needed.

HAIR LOSS AND BALDNESS

When the hair shaft is lost and the hair follicle cannot regenerate, male-pattern baldness, or *alopecia,* occurs. Permanent hair loss is associated with a familial history and occurs during the aging process, earlier in some individuals than others. Drugs also known to cause alopecia include anticancer (antineoplastic) agents, sulfonamides, anticonvulsants, aminoglycosides, and some nonsteroidal antiinflammatory drugs (NSAIDs), such as indomethacin. Severe febrile illnesses, pregnancy, myxedema (condition resulting from hypothyroidism), and cancer therapies are some of the health conditions contributing to temporary hair loss.

A 2% minoxidil (Rogaine) solution has been approved by the FDA for treating baldness for men and women. A 5% solution is approved for men only. Minoxidil causes vasodilation, increasing cutaneous blood flow. The increased blood flow tends to stimulate hair follicle growth. When the drug is discontinued, however, hair loss occurs within 3 to 4 months. Systemic absorption of minoxidil is minimal, so adverse reactions seldom occur. Occasionally, headaches and a slight decrease in systolic blood pressure occur.

Finasteride (Propecia, Proscar) is an oral drug used for male baldness. It is available in 1-mg tablets. (A 5-mg tablet is prescribed for benign prostatic hyperplasia.) For growing hair, finasteride is effective in 50% of men. It has been reported that it is relatively ineffective in growing hair in older men, even with an increased dose.

SUNSCREENS

Chemical screens are those that absorb ultraviolet (UV) radiation, and physical screens are those that scatter UV radiation. Chemical screens account for most FDA-approved sunscreens. Most absorb UV-UVB, less than half absorb UVA, and one (avobenzone) protects against UVA and UVB. Physical screens prevent skin penetration of UV. Examples of these products are titanium dioxide and zinc oxide, generally applied to limited areas of the body such as the nose and ears.

UV radiation causes many problems, including premature aging of the skin, burns, and skin cancer. Sunscreens protect against sunburn photosensitivity to selected drugs but do not guard against melanoma and basal cell carcinoma. Sun protection factor (SPF) is a rating on sunscreen products of protection against UVB radiation. The highest rating approved by the FDA is SPF 30+. A higher protection rating is not proportional to the amount of UVB radiation blocked. For example, SPF 15 blocks 93% of UVB, and SPF 30 blocks 96.7%. Sunscreens with SPF greater than 15 are recommended for children older than 6 months and all adults.

The FDA requires UVA ratings and separate labeling for UVB and UVA SPF protection. Use of the term *sunblock* is not permitted. Lack of UVA protection is to be clearly indicated on the product label. The FDA requirements for sunscreens are summarized in Table 50-2.

Using common sense is the best way to protect the skin. UV radiation is most intense between 10:00 AM and 3:00 PM. Apply a sunscreen appropriate for the circumstances at least 30 minutes before going out into the sun. (For sunscreens with PABA or padimate, allow 2 hours). Sunscreen will protect for about 2 hours when applied properly and not exposed to moisture through swimming or sweating. Wearing protective clothing (e.g., a wide-brimmed hat, sunglasses, long-sleeved shirt) is a good idea. When using DEET insect repellent with sunscreen, apply DEET first to avoid decreased effectiveness of sunscreen. Contact dermatitis and photosensitivity reaction are adverse effects and occur most commonly with PABA derivatives.

BURNS AND BURN PREPARATIONS

Burns from heat (thermal burns, most common kind of burn injury), electricity (electrical burns), and chemical agents (chemical burns) can cause skin lesions. Burns are classified according to degree and tissue depth (Table 50-3).

Moderately severe sunburn is an example of a first-degree burn. Severe sunburn can result in a second-degree burn. Burns needs immediate attention, regardless of the degree and tissue depth of the burn.

For first-degree (superficial epidermal and superficial partial thickness) and minor burns, a cold, wet compress is applied to the burned area to constrict blood vessels and decrease swelling. This treatment also decreases the amount of pain. The quicker the burn area is cooled, the less tissue damage occurs. No greasy ointment or dressing should be applied, because they can inhibit heat loss from the burn and increase damage to the tissues. A nonprescription antibiotic, such as bacitracin with polymyxin B (Polysporin), may be used for minor burns. Used separately, polymyxin B and neomycin are not drugs of choice, because they do not have a broad-spectrum effect. With chemical burns, clothing should be removed immediately and the skin thoroughly flushed with water.

Persons with second (deep thickness)—and third-degree (full thickness) burns that involve the dermis and subcutaneous tissue should undergo treatment at a burn center or other hospital setting. Intravenous therapy is started immediately, and a nonnarcotic or narcotic analgesic is given for pain.

TABLE 50-2 FDA REQUIREMENTS FOR SUNSCREENS

PROTECTION	UVB RATING AND LABELING	UVA RATING AND LABELING
Low	UVB SPF 2-14	*
Medium	UVB SPF 15-29	**
High	UVB SPF 30-50	***
Highest	UVB SPF 50+	****

FDA, U. S. Food and Drug Administration; *UV,* ultraviolet.

TABLE 50-3 DEGREE AND TISSUE DEPTH OF BURNS

TYPE	DEGREE	DEPTH	CHARACTERISTICS
Superficial epidermal	First	Epidermis	Erythema, painful
Partial-thickness superficial	First-second	Epidermis, upper dermis	Blistering, very painful
Deep-thickness	Second	Epidermis, lower dermis	Mottled, blistering, intense pain
Full-thickness	Third	Epidermis, dermis, nerve ending involvement, subcutaneous tissue	Pearly white skin, charred, no pain

Burn areas are cleansed with sterile saline solution and an antiseptic such as povidone-iodine (Betadine). If a povidone-iodine solution is used, it should be determined that the patient is not allergic to iodine or seafood. Broad-spectrum topical antibacterials, usually effective against many gram-positive and gram-negative organisms and yeast infections, are applied to burn areas to prevent infection. Examples of these antibacterials include mafenide acetate (Sulfamylon), silver sulfadiazine (Silvadene), and silver nitrate 0.5% solution. Prototype Drug Chart 50-1 lists the pharmacologic data for the antibacterial agent mafenide acetate (Sulfamylon).

Analgesics are required for pain control, usually controlled substances and NSAIDs.

Mafenide Acetate

Pharmacokinetics Mafenide acetate is absorbed through the skin and metabolized by the liver to a metabolite. The drug is excreted in the urine. The drug and its metabolite are strong carbonic anhydrase inhibitors, which may lead to acid-base imbalances (e.g., metabolic acidosis, respiratory alkalosis) and fluid loss from the mild diuretic effect. If respiration becomes rapid, labored, or shallow, the cream should be discontinued for a few days until the acid-base balance is restored.

Pharmacodynamics Mafenide, a sulfonamide derivative, interferes with bacterial cell-wall synthesis and metabolism and is bacteriostatic. It is used as a topical water-soluble antibacterial agent to prevent or combat burn infection. After the burn is cleansed and debrided, $\frac{1}{16}$-inch of mafenide cream is applied to the affected area one to two times daily and covered lightly with a dressing. The patient may complain of a burning sensation when the drug is applied.

Table 50-4 lists selected topical medications for burns and their dosages, uses, and considerations.

Silver Sulfadiazine

Silver sulfadiazine (Silvadene, SSD) is commonly used to prevent and treat sepsis in second- and third-degree burns. It acts on the cell membrane and cell wall to produce

PROTOTYPE DRUG CHART 50-1

Mafenide Acetate

Drug Class Topical antiinfective Trade Names: Sulfamylon Cream Pregnancy Category: C	**Dosage** A/C: Topical: Apply $\frac{1}{16}$-inch layer evenly to affected area b.i.d.; reapply PRN
Contraindications Hypersensitivity, inhalation injury Caution: Renal failure	**Drug-Lab-Food Interactions** None known
Pharmacokinetics Absorption: Some absorbed Distribution: PB: UK Metabolism: t$\frac{1}{2}$: UK Excretion: In urine	**Pharmacodynamics** Topical: Onset: On contact Peak: 2-4 h Duration: As long as applied
Therapeutic Effects/Uses To treat second- and third-degree burns; to prevent organism invasion of burned tissue areas; to treat burn infections Mode of Action: Inhibits bacterial cell wall synthesis	
Side Effects Rash, burning sensation, urticaria, pruritus, swelling	**Adverse Reactions** Metabolic acidosis, respiratory alkalosis, blistering, superinfection Life-threatening: Bone marrow suppression, fatal hemolytic anemia

A, Adult; *b.i.d.,* twice a day; *C,* child; *h,* hour; *PB,* protein-binding; *PRN,* as needed; *t*$\frac{1}{2}$, half-life; *UK,* unknown.

TABLE 50-4 TOPICAL ANTIINFECTIVES: BURNS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
mafenide acetate (Sulfamylon) silver nitrate	See Prototype Drug Chart 50-1. 0.5 sol; 10%, 25% sticks; apply only to affected area 2-3 times/wk for 2-3 wk	For second- and third-degree burns. Dressings are soaked in 0.5% silver nitrate solution and then removed before they dry. Effective against some gram-negative organisms. May cause electrolyte imbalance (hypokalemia) if used extensively. Pregnancy category: C; PB: NA; t$\frac{1}{2}$: NA
silver sulfadiazine (Silvadene, SSD)	1% Cream, apply b.i.d. in $\frac{1}{16}$-inch layer	To prevent and treat infection of second- and third-degree burns. Ten percent of drug is absorbed. Excessive use or extensive application area may cause sulfa crystals (crystalluria). Pregnancy category: C; PB: NA; t$\frac{1}{2}$: NA

b.i.d., Twice a day; *d,* day; *NA,* not applicable; *PB,* protein-binding; *t*$\frac{1}{2}$, half-life; *sol,* solution; *wk,* week.

bactericidal effects. Unlike mafenide, it is not a carbonic anhydrase inhibitor. It is contraindicated at or near term pregnancy.

One percent or less of the silver is absorbed, and up to 10% of sulfadiazine is absorbed. Side effects and adverse reactions may include skin discoloration, burning sensation, rashes, erythema multiforme, skin necrosis, and possible leukopenia.

Nursing Process
Patient-Centered Collaborative Care

Topical Antiinfectives: Burns

Assessment
- Assess burned tissue for infection (foul odor, purulent drainage, erythema, heat).
- Culture an oozing wound.
- Check patient's vital signs. Report abnormal findings, such as elevated temperature.
- Determine fluid status. Report signs and symptoms of hypovolemia or hypervolemia.

Nursing Diagnoses
- Impairment of skin integrity related to disruption of skin surface secondary to burns
- Risk for imbalanced fluid volume related to fluid shifts secondary to burns
- Deficient knowledge related to management of burns
- Risk for infection related to loss of skin integrity
- Acute pain related to thermal injury
- Risk for disturbed body image related to loss of skin integrity

Planning
- The patient will remain free from infection.
- The patient's pain will be decreased or tolerable.

Nursing Interventions
- Administer prescribed analgesia before application, if needed.
- Cleanse burned tissue sites using aseptic technique.
- Apply topical antibacterial drug and dressing with sterile technique.
- Monitor patient's fluid balance and renal function.
- Monitor patient for side effects and adverse reactions to topical drug.
- Monitor patient's vital signs, and be alert for signs of infection. Use with caution in patients with acute renal failure.
- Closely monitor patient's acid-base balance, especially in the presence of pulmonary or renal dysfunction.
- Store drug in dry place at room temperature.

Patient Teaching
General
- Instruct patient and family about pain management, medications used to treat burns, and signs of complications from burns, such as fluid excess or deficit.

Self-Administration
- Explain to patient and family the care given to the burned tissue areas using aseptic technique.
- Teach patient and family how to apply topical agent and dressings to burned areas.
- Teach patient and family about signs and symptoms of infection and to report them promptly to the health care provider.

Evaluation
- Evaluate patient and family knowledge of burn management.
- Patient will remain in normovolemic state and be free of complications from burns (e.g., hypervolemia, hypovolemia).
- Evaluate effectiveness of treatment interventions to burned tissue areas by determining whether healing is proceeding and sites are free from infection.

CRITICAL THINKING CASE STUDY

MG, a 15-year-old patient, complains about blackheads and large, raised pimples on her face. She seeks help from a health care provider.

1. To assist in identifying her skin problem, what should the health history and assessment include?
2. Which nonpharmacologic measures might the nurse discuss with MG in caring for her skin condition?

MG's skin disorder does not improve. Her health care provider says she has acne vulgaris and has prescribed benzoyl peroxide and oral tetracycline.

3. M.G. asks the nurse how to use benzoyl peroxide. What should the explanation of the method and frequency for use of benzoyl peroxide include?
4. What should be included in the patient teaching related to the use of oral tetracycline?
5. What other agents for acne might MG use? Explain their uses and side effects.
6. MG asks if she will have to remain on benzoyl peroxide and oral tetracycline for the rest of her life. What is the nurse's best response or course of action? Explain your answer.

NCLEX STUDY QUESTIONS

1. The nurse is reviewing a patient's list of medications. The patient asks, "What do kerolytic agents remove?" What is the nurse's best response?
   - a. A horny layer of dermis
   - b. A horny layer of epidermis
   - c. Erythematous lesions
   - d. Hair follicles
2. A male patient is to begin therapy with isotretinoin and asks, "What do I have to remember to do while taking this medicine?" What is the nurse's best response? (Select all that apply.)
   - a. Avoid sunlight.
   - b. Monitor your weight.
   - c. Keep appointments for laboratory tests.
   - d. Avoid pregnancy.
   - e. Always take the drug with food.
3. The nurse is doing health teaching with a patient with psoriasis. Which is a nursing implication of a biologic agent such as infliximab (Remicade) for the management of psoriasis?
   - a. Monitor daily weight.
   - b. Monitor electrolytes.
   - c. Monitor urine output.
   - d. Monitor CBC.
4. A 55-year-old man is concerned about hair loss. The nurse expects that the patient's baldness may be treated with which oral drug?
   - a. dexamethasone
   - b. PABA
   - c. mupirocin
   - d. finasteride
5. The nurse reviews the patient's medication history. Based on the patient's prolonged use of topical glucocorticoids, what could the nursing assessment include? (Select all that apply.)
   - a. Weight gain
   - b. Thinning of the skin
   - c. Erythematous lesions
   - d. Purpura
   - e. Urinary retention
6. A 20-year-old woman comes to the clinic for follow-up related to isotretinoin use. The nurse reviews the iPLEDGE program, which includes which important information? (Select all that apply.)
   - a. One method of contraception must be used throughout treatment.
   - b. A review of iPLEDGE educational materials
   - c. A negative pregnancy test is required before each monthly refill.
   - d. Informed consent is not required.
   - e. A prescription for 60 days' worth of drug is to be given.
7. The school nurse prepares a program for junior high school students on sun safety. What is important information to include? (Select all that apply.)
   - a. Sunscreen products should contain information about UVA and UVB SPF protection.
   - b. UVB radiation is greatest between 10 AM and 3 PM.
   - c. Clouds block radiation, so sunscreen is not needed on cloudy days.
   - d. SPF should be at least 15 in sunscreen products.
   - e. Sunscreen is to be applied once daily.
8. A patient is receiving etanercept (Enbrel). Which nursing interventions are appropriate for this patient? (Select all that apply.)
   - a. Drug is administered by subQ route.
   - b. PPD is required before start of therapy.
   - c. Monitor for injection site reaction.
   - d. Monitor for seizures.
   - e. Monitor for heart failure.
9. The nurse is teaching the patient about the medication clobetasol (Clobex) to be started today. What information needs to be included in the teaching session? (Select all that apply.)
   - a. Appropriate treatment for 6 months' duration
   - b. Can apply lotion to all body parts
   - c. Super–high-potency corticosteroid
   - d. Maximum dose is 50 g/wk
   - e. Occlusive dressing speeds healing

Answers: 1, b; 2, a, c, d; 3, d; 4, d; 5, b, d; 6, b, c; 7, a, b, d; 8, a, b, c, e; 9, c, d.

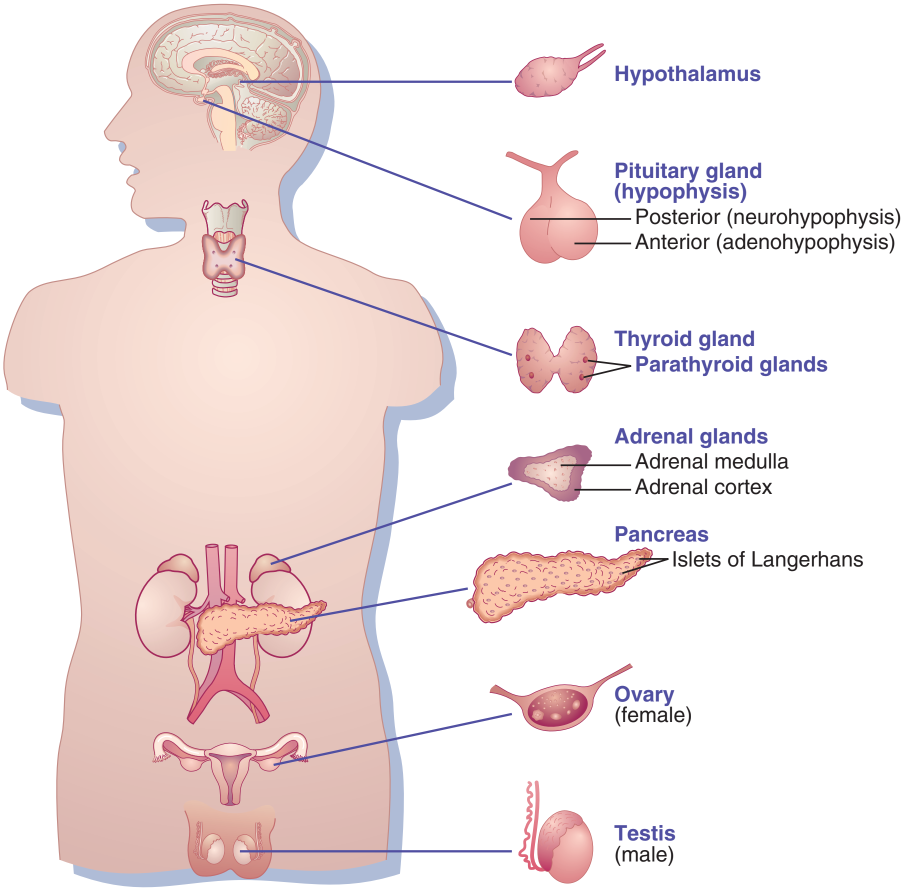
UNIT XVII

Endocrine Agents

The endocrine system consists of ductless glands that secrete hormones into the bloodstream. *Hormones* are chemical substances synthesized from amino acids and cholesterol that act on body tissues and organs and affect cellular activity. Hormones can be divided into two categories: (1) proteins or small peptides and (2) steroids. Hormones from the adrenal glands and the gonads are steroid hormones; the others are protein hormones. The *endocrine glands* include the pituitary (hypophysis), thyroid, parathyroid, adrenals, gonads, and pancreas. Figure XVII-1 illustrates the location and functions of these glands. This unit discusses the hormonal activity of the endocrine glands.

PITUITARY GLAND

The *pituitary gland,* or hypophysis, is located at the base of the brain and has two lobes, the anterior pituitary gland (adenohypophysis) and the posterior pituitary gland (neurohypophysis). The anterior pituitary gland is called the *master gland* because it secretes hormones that stimulate the release of other hormones from target glands, including the thyroid, adrenals, and gonads. The posterior pituitary gland secretes two neurohormones—antidiuretic hormone (ADH), or vasopressin, and oxytocin. Figure XVII-2 shows the anterior and posterior pituitary glands and the types of hormones secreted.



Hypothalamus
Pituitary gland (hypophysis)
Posterior (neurohypophysis)
Anterior (adenohypophysis)
Thyroid gland
Parathyroid glands
Adrenal glands
Adrenal medulla
Adrenal cortex
Pancreas
Islets of Langerhans
Ovary (female)
Testis (male)

FIGURE XVII–1 The endocrine glands.

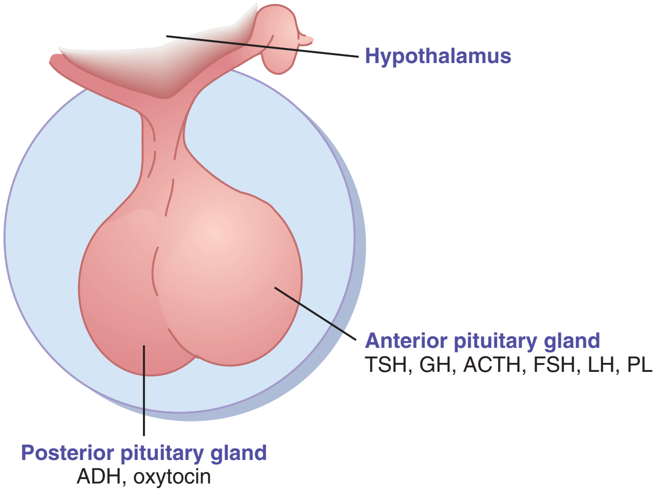


FIGURE XVII–2 The anterior and posterior pituitary glands. *ACTH,* Adrenocorticotropic hormone; *ADH,* antidiuretic hormone; *FSH,* follicle-stimulating hormone; *GH,* growth hormone; *LH,* luteinizing hormone; *PL,* prolactin; *TSH,* thyroid-stimulating hormone.

Anterior Pituitary Gland

The anterior pituitary hormones are (1) thyroid-stimulating hormone (TSH), (2) adrenocorticotropic hormone (ACTH), and (3) the gonadotropins (follicle-stimulating hormone [FSH] and luteinizing hormone [LH]). They control the synthesis and release of hormones from the thyroid, adrenals, and ovaries. Other hormones secreted from the anterior pituitary gland include growth hormone (GH), prolactin (PL), and melanocyte-stimulating hormone (MSH). The amount of each hormone secreted from the anterior pituitary gland is regulated by a negative feedback system. If excess hormone is secreted from the target gland, hormonal release from the anterior pituitary gland is suppressed. If there is a lack of hormone secretion from the target gland, there will be an increase in that particular anterior pituitary hormone.

Thyroid-Stimulating Hormone

The anterior pituitary gland secretes TSH in response to thyroid-releasing hormone (TRH) from the hypothalamus. TSH, or thyrotropic hormone, stimulates the release of thyroxine (T_4) and triiodothyronine (T_3) from the thyroid gland. Hypersecretion of TSH can cause hyperthyroidism and thyroid enlargement, and hyposecretion can cause hypothyroidism. Serum TSH levels should be checked to determine whether there is a TSH deficit or excess. TSH and T_4 levels are frequently measured to differentiate pituitary from thyroid dysfunction. A decreased T_4 level and a normal or elevated TSH level can indicate a thyroid disorder.

Adrenocorticotropic Hormone

Secretion of ACTH occurs in response to corticotropin-releasing factor (CRF) from the hypothalamus. ACTH from the anterior pituitary gland stimulates the release of glucocorticoids (cortisol), mineralocorticoids (aldosterone), and androgen from the adrenal cortex (adrenal glands). Elevated serum cortisol from the adrenal cortex inhibits ACTH and CRF release. When the cortisol level is low, ACTH secretion is stimulated, which in turn stimulates the adrenal cortex to release more cortisol. More ACTH is secreted in the morning than in the evening.

Gonadotropic Hormones

The gonadotropic hormones regulate hormone secretion from the ovaries and testes (the gonads). The anterior pituitary gland secretes the gonadotropic hormones FSH, LH, and prolactin. FSH promotes the maturation of follicles in the ovaries and initiates sperm production in the testes. LH combines with FSH in follicle maturation and estrogen production and promotes secretion of androgens from the testes. Prolactin stimulates milk formation in the glandular breast tissue after childbirth. Estrogen, progesterone, and testosterone are discussed in Chapter 56, Drugs for Women's Reproductive Health and Menopause, and Chapter 57, Drugs for Men's Health and Reproductive Disorders, respectively.

Growth Hormone

GH, or somatotropic hormone (STH), acts on all body tissues, particularly the bones and skeletal muscles. The amount of GH secreted is regulated by growth hormone–releasing hormone (GH-RH) and growth hormone–inhibiting hormone (GH-IH, or somatostatin) from the hypothalamus. Sympathomimetics, serotonin, and glucocorticoids can inhibit the secretion of GH.

Posterior Pituitary Gland

The posterior pituitary gland (neurohypophysis) secretes ADH (vasopressin) and oxytocin. Interconnecting nerve fibers between the hypothalamus and the posterior pituitary gland allow ADH and oxytocin to be synthesized in the hypothalamus and stored in the posterior pituitary gland. ADH increases the reabsorption of water from the renal tubules, returning it to the systemic circulation. Secretion of ADH is regulated by the serum osmolality (concentration of the vascular fluid). An increase in serum osmolality increases the release of ADH from the posterior pituitary gland; more water is then absorbed from the renal tubules to dilute the vascular fluid. Excess ADH can overload the vascular system. A decrease in serum osmolality decreases the release of ADH, promoting more water excretion from the renal tubules. Oxytocin stimulates contraction of the smooth muscle of the uterus; it is discussed in Chapter 54, Female Reproductive Cycle II: Labor, Delivery, and Preterm Neonatal Drugs.

THYROID GLAND

Located anterior to the trachea, the thyroid gland has two lobes that are connected by a bridge of thyroid tissue. The thyroid gland secretes two hormones, thyroxine (T_4) and triiodothyronine (T_3 liothyronine). These hormones affect nearly every tissue and organ by controlling their metabolic rate and activity. Stimulation by the thyroid hormones results in an increase in cardiac output, oxygen consumption, carbohydrate use, protein synthesis, and breakdown of fat (lipolysis). Thyroid hormones also affect body heat regulation and the menstrual cycle. Thyroid hormone levels in the blood are regulated by negative feedback. The anterior pituitary gland secretes TSH, which stimulates the thyroid gland to produce T_4 and T_3. An increased amount of circulating thyroid hormones suppresses the release of TSH, and a decreased amount increases the release of TSH by the adenohypophysis.

PARATHYROID GLANDS

There are four parathyroid glands (two pairs) that lie on the dorsal surface of the thyroid gland. The parathyroid gland secretes parathormone, or parathyroid hormone (PTH), which regulates calcium levels in the blood. A decrease in serum calcium stimulates the release of PTH. PTH increases calcium levels by (1) mobilizing calcium from the bone, (2) promoting calcium absorption from the intestine, and (3) promoting calcium reabsorption from the renal tubules. Calcitonin, a hormone produced primarily by the thyroid gland and to a lesser extent by the parathyroid and thymus glands, inhibits calcium reabsorption by bone and increases renal excretion of calcium. Calcitonin counteracts the action of PTH.

ADRENAL GLANDS

The adrenal glands, located at the top of each kidney, consist of two separate sections—the adrenal medulla (the inner section) and the adrenal cortex (the section surrounding the adrenal medulla). The adrenal medulla releases the catecholamines epinephrine and norepinephrine and is linked with the sympathetic nervous system. The adrenal cortex produces two major types of hormones (corticosteroids)—glucocorticoids and mineralocorticoids. The principal glucocorticoid is cortisol, and the principal mineralocorticoid is aldosterone. The adrenal cortex also produces small amounts of androgen, estrogen, and progestin. Glucocorticoids have a profound influence on electrolytes and the metabolism of carbohydrates, protein, and fat, and glucocorticoid deficiencies can result in serious illness and even death.

PANCREAS

The pancreas, located to the left of and behind the stomach, is both an exocrine and an endocrine gland. The exocrine section of the pancreas secretes digestive enzymes into the duodenum; these enzymes are discussed in Unit XV, Gastrointestinal Agents. The endocrine section has cell clusters called *islets of Langerhans.* The alpha islet cells produce glucagon, which breaks glycogen down to glucose in the liver, and the beta cells secrete insulin, which regulates glucose metabolism. Insulin, an antidiabetic agent, is used to control diabetes mellitus. Antidiabetic agents are discussed in Chapter 52.

DRUGS FOR ENDOCRINE DISORDERS

Chapter 51 (Endocrine Drugs: Pituitary, Thyroid, Parathyroid, and Adrenal Disorders) and Chapter 52 (Antidiabetics) discuss the drugs used to diagnose and treat endocrine disorders. Chapter 51 discusses the agents for disorders involving the pituitary gland, thyroid gland, parathyroid gland, adrenal gland, and ADH. The parenteral and oral antidiabetic drugs (hypoglycemic drugs) are described in Chapter 52.

OBJECTIVES

- Compare the hormones secreted from the adenohypophysis and the neurohypophysis.
- Differentiate the actions and uses of the pituitary hormones: thyroxine (T_4), triiodothyronine (T_3), parathyroid hormone (PTH), and glucocorticoids.
- Differentiate the side effects of thyroxine (T_4) and triiodothyronine (T_3).
- Apply the nursing process, including patient teaching, of drug therapy related to hormonal replacement or hormonal inhibition for the pituitary, thyroid, parathyroid, and adrenal glands.

This chapter describes drugs used for hormonal replacement and for inhibition of hormonal secretion from the pituitary, thyroid, parathyroid, and adrenal glands. Before reading Chapters 51 and 52, review the introduction to Unit XVII, which describes the locations of the endocrine glands and the hormones they secrete. Knowledge of the various **endocrine** (ductless glands that produce internal secretions that flow to all parts of the body) hormones and their functions facilitates an understanding of the drugs that act on the endocrine glands.

PITUITARY GLAND

Anterior Lobe

The pituitary gland, or **hypophysis,** has an anterior and a posterior lobe. The anterior pituitary gland, called the **adenohypophysis,** secretes the following hormones that target glands and tissues:

- Growth hormone (GH), which stimulates growth in tissue and bone
- Thyroid-stimulating hormone (TSH), which acts on the thyroid gland
- Adrenocorticotropic hormone (ACTH), which stimulates the adrenal gland
- Gonadotropins (follicle-stimulating hormone [FSH] and luteinizing hormone [LH]), which affect the ovaries.

Drugs with adenohypophyseal properties used to stimulate or inhibit glandular activity are discussed according to their therapeutic use. The negative feedback system that controls the amount of hormonal secretion from the pituitary gland and the target gland is discussed in the introduction to Unit XVII.

Growth Hormone

Two hypothalamic hormones regulate GH: (1) growth hormone–releasing hormone (GH-RH) and (2) growth hormone–inhibiting hormone (GH-IH; somatostatin). Growth hormone does not have a specific target gland. It affects body tissues and bone; GH replacement stimulates linear growth when there is a GH deficiency. Growth hormone drugs cannot be given orally, because they are inactivated by gastrointestinal enzymes. Subcutaneous (subQ) or intramuscular (IM) administration of GH is necessary.

If a child's height is well below the standard for a specified age, GH deficiency may be diagnosed, and dwarfism can result. Growth hormone replacement is very expensive; therefore, various tests are performed to determine if this therapy is essential. Because GH acts on newly forming bone, it must be administered before the epiphyses are fused. Administration of GH over several years can increase height by a foot. Prolonged GH therapy can antagonize insulin secretion and eventually cause diabetes mellitus. Athletes should be advised not to take GH to build muscle and physique because of its effects on blood sugar and other side effects.

Drug Therapy: Growth Hormone Deficiency

Somatropin (Genotropin) is a growth hormone used to treat growth failure in children because of pituitary GH deficiency. Somatropin is a product that has the identical amino acid sequence as human growth hormone. Somatropin is contraindicated in pediatric patients who have growth deficiency due to Prader-Willi syndrome and are severely obese or who have severe respiratory impairment, because fatalities associated with these risk factors have been reported.

Drug Therapy: Growth Hormone Excess

Gigantism (excessive growth during childhood) and **acromegaly** (excessive growth after puberty) can occur with GH hypersecretion and are frequently caused by a pituitary tumor. If the tumor cannot be destroyed by radiation, the prolactin-release inhibitor bromocriptine can inhibit the release of GH from the pituitary gland.

Octreotide (Sandostatin) is a potent synthetic somatostatin used to suppress GH release. It can be used alone or with surgery or radiation. This drug is expensive. GI side effects are common. This drug can also be used for severe diarrhea resulting from carcinoid tumors.

Table 51-1 lists the drugs used to replace or inhibit GH and their dosages, uses, and considerations.

Thyroid-Stimulating Hormone

The adenohypophysis secretes **thyroid-stimulating hormone** (TSH) in response to thyroid-releasing hormone (TRH) from the hypothalamus, and TSH stimulates the thyroid gland to release thyroxine (T_4) and triiodothyronine (T_3, or liothyronine). Excess TSH secretion can cause hyperthyroidism, and a TSH deficit can cause hypothyroidism. Hypothyroidism may be caused by a thyroid gland disorder (primary cause) or a decrease in TSH secretion (secondary cause). Thyrotropin (Thytropar), a purified extract of TSH, is used as a diagnostic agent to differentiate between primary and secondary hypothyroidism (see Table 51-1).

Adrenocorticotropic Hormone

The hypothalamus releases corticotropin-releasing factor (CRF), which stimulates the pituitary corticotrophs to secrete **adrenocorticotropic hormone** (ACTH). ACTH secretion stimulates the release of glucocorticoids (cortisol), mineralocorticoids (aldosterone), and androgen from the adrenal cortex. Usually ACTH and cortisol secretions follow a diurnal rhythm in which the ACTH and cortisol secretion is higher in the early morning and then decreases throughout the day. Stresses such as surgery, sepsis, and trauma override the diurnal rhythm, causing an increase in secretions of ACTH and cortisol.

The ACTH drug corticotropin (Acthar) is used to diagnose adrenal gland disorders, to treat adrenal gland insufficiency, and as an antiinflammatory drug in the treatment of allergic response. Administration of ACTH intravenously (IV) should increase the serum cortisol level in 30 to 60 minutes if the adrenal gland is functioning. If steroid

TABLE 51-1 ANTERIOR AND POSTERIOR PITUITARY HORMONES

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Anterior Lobe		
Growth Hormone (GH)		
somatropin (Nutropin, Genotropin)	C: subQ/IM: Nutropin: 0.006 mg/kg/d; Genotropin: 0.04 mg/kg in 6-7 equal daily doses; *max:* 0.08 mg/kg/wk	For growth hormone deficiency. Promotes bone growth at epiphyseal plates of long bones. Pregnancy category: Nutropin: C; Genotropin: B; PB: 20%; t½: 15-60 min
Growth Hormone Suppressant Drugs		
bromocriptine mesylate (Parlodel)	A: PO: 1.25-2.5 mg/d for 3 d; range: 10-30 mg/d; *max:* 100 mg/d	For acromegaly. Also used with pituitary radiation or surgery to decrease GH levels. Decreases lactation and prolactinoma. Pregnancy category: B; PB: 93%; t½: 3-6 h
octreotide acetate (Sandostatin)	A: subQ: 50-100 mcg t.i.d.	For acromegaly. To treat severe diarrhea associated with metastatic carcinoid and other tumors. Pregnancy category: B; PB: 65%; t½: 1.5 h
lanreotide acetate (Somatuline Depot)	A: subQ: Initially 90 mg q4wk for 3 mo; then 60-120 mg q4wk for 4 mo	To suppress GH. Monitor glucose levels. Pregnancy category: C; PB: 69%-78%; t½: 23-30 d
Thyroid-Stimulating Hormone (TSH)		
thyrotropin (Thyrogen)	Thyroid cancer: A: IM: 0.9 mg into gluteus maximus, repeat in 24 h for 2 doses; *max:* 0.9 mg/d	For thyroid cancer. . Radioiodine study follows last injection. Pregnancy category: C; PB: UK; t½: 15-35 h
Adrenocorticotropic Hormone (ACTH)		
corticotropin (H.P. Acthar gel)	See Prototype Drug Chart 51-1.	
cosyntropin (Cortrosyn)	A/C: >2 y: IM/IV: 0.25 mg over 2 min or slow infusion over 6 h C: <2 y: IM/IV: 0.125 mg slow infusion over 6 h	For diagnostic testing to differentiate between pituitary and adrenal cause of adrenal insufficiency. Obtain plasma cortisol level before and 30 min after administration. Pregnancy category: C; PB: UK; t½: 15 min
Posterior Lobe		
Antidiuretic Hormone (ADH)		
desmopressin acetate (DDAVP, Stimate)	DDAVP: A: Intranasal: 0.1-0.4 mL/d in divided doses Stimate: A: subQ/IV: 0.2-0.4 mcg A/C: >11 mo: intranasal: 150 mcg/kg	For DI, hemophilia A, and von Willebrand disease. Can have a long duration of action (5-21 h). Pregnancy category: B; PB: UK; t½: 1.5-2.5 h
vasopressin (aqueous) (Pitressin)	Diabetes insipidus: A: subQ/IM: 5-10 units, b.i.d./q.i.d. C: subQ/IM: 2.5-10 units, b.i.d./q.i.d.	For DI. For relief of intestinal distention. Decreases GI bleeding from esophageal varices. Can also be given intranasally. Promotes reabsorption of water from renal tubules. Duration of action is 2-8 h. Pregnancy category: C; PB: UK; t½: 15 min
demeclocycline (Declomycin)	A: PO: 600 mg/d in 3-4 divided doses	For treatment of SIADH. Inhibits ADH-induced water reabsorption in renal distal tubules. Closely monitor sodium levels. Pregnancy category: C; PB: 99%; t½: 12 h
conivaptan (Vaprisol)	A: IV: LD 20 mg over 30 min; maint: 20 mg continuous IV over 24 h; then 20 mg/d for 1-3 d; *max:* 4 days therapy	For hypervolemic hyponatremia associated with SIADH. Closely monitor sodium levels. Pregnancy category: C; PB: 99%; t½: 5 h
tolvaptan (Samsca)	A: PO: Initially 15 mg/d; then 15-30 mg/d; *max:* 60 mg/d	For hyponatremia associated with SIADH. Closely monitor sodium levels. Pregnancy category: C; PB: 99%; t½: 12 h

A, Adult; *ADH,* antidiuretic hormone; *b.i.d.,* twice a day; *C,* child; *d,* day; *DI,* diabetes insipidus; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *LD,* loading dose; *min,* minute; *NSS,* normal saline solution; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *subQ,* subcutaneous; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week; *y,* year; *>,* greater than; *<,* less than.

deficiency is caused by pituitary insufficiency, ACTH should eventually stimulate cortisol production. ACTH decreases the symptoms of multiple sclerosis during its exacerbation phase. Prototype Drug Chart 51-1 lists the pharmacologic data for repository corticotropin.

Pharmacokinetics Corticotropin stimulates the adrenal gland to secrete corticosteroids. The aqueous and gel preparations are well absorbed into the circulation. Zinc is added to some formulations to slow the absorption rate. A portion of the drug is bound to protein; however, the percentage is unknown. The half-life of the drug is 15 to 20 minutes. It is excreted in the urine.

PROTOTYPE DRUG CHART 51-1

Repository Corticotropin

Drug Class
Pituitary adrenocorticotropic hormone
Trade Name: H.P. Acthar Gel
Pregnancy Category: C

Dosage
Inflammation:
A/C: subQ/IM: 40-80 units, q24-72h; *max:* 80 units/d
Acute multiple sclerosis (MS):
A: subQ/IM: 80-120 units/d for 2-3 wk; *max:* 120 units/d

Contraindications
Severe fungal infection, adrenal insufficiency, Cushing's syndrome, HF, peptic ulcer, osterporosis, scleroderma, ocular herpes simplex, recent surgery
Caution: Hepatic disease, psychiatric disorders, cardiac disease, diabetes mellitus, renal impairment, hypertension, hypothyroidism, myasthenia gravis

Drug-Lab-Food Interactions
Drug: Increase potential for ulcer formation and hypoprothrombinemia with aspirin and NSAIDs; may increase potassium loss with thiazide and loop diuretics; barbiturates, phenytoin decrease corticotropin effects; estrogens increase corticotropin effects

Pharmacokinetics
Absorption: IM: Well absorbed
Distribution: PB: UK
Metabolism: t½: 15-20 min
Excretion: In urine

Pharmacodynamics
IM: Onset: <6 h
Peak: 6-18 h
Duration: 12-24 h
IV: Onset: UK
Peak: 1 h
Duration: UK

Therapeutic Effects/Uses
To diagnose adrenocortical disorders; acts as antiinflammatory agent; to treat acute MS
Mode of Action: Stimulates adrenal cortex to secrete cortisol

Side Effects
Nausea, vomiting, diarrhea, constipation, mood swing (euphoria to depression), petechiae, water and sodium retention, hypokalemia, hypocalcemia, acne

Adverse Reactions
Edema, ecchymosis, osteoporosis, muscle atrophy, growth retardation, decreased wound healing, cataracts, glaucoma, seizures, menstrual irregularities, hypertension,
Life-threatening: Ulcer perforation, pancreatitis

A, Adult; *HF,* heart failure; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *MS,* multiple sclerosis; *q.i.d.,* four times a day; *subQ,* subcutaneous; *PB,* protein-binding; *t½,* half-life; *UK,* unknown; *wk,* week; *<,* less than.

Pharmacodynamics Corticotropin suppresses the inflammatory and immune responses. It is also prescribed to treat adrenal insufficiency secondary to inadequate corticotropin secretion. The drug is administered IM and IV. Its onset of action, peak concentration time, and duration of action are prolonged when it is injected IM. The IV preparation is in aqueous form; therefore its actions are faster than those of the gel and zinc-additive preparations.

Drug Interactions. Corticotropin has numerous drug interactions. Diuretics and anti-*Pseudomonas* penicillins such as piperacillin can decrease the serum potassium level (hypokalemia). If the patient is taking a digitalis preparation and hypokalemia is present, digitalis toxicity can result. Phenytoin, rifampin, and barbiturates increase the metabolic rate, which can decrease the effect of the ACTH drug. Persons with diabetes may need increased insulin and oral antidiabetic (hypoglycemic) drugs because ACTH stimulates cortisol secretion, which increases the blood sugar level.

Posterior Lobe

The posterior pituitary gland, known as the **neurohypophysis,** secretes **antidiuretic hormone (ADH)** (vasopressin) and oxytocin. (Oxytocin is discussed in Chapter 54.)

ADH promotes water reabsorption from the renal tubules to maintain water balance in the body fluids. When there is a deficiency of ADH, large amounts of water are excreted by the kidneys. This condition, called **diabetes insipidus (DI),** can lead to severe fluid volume deficit and electrolyte imbalances. Head injury and brain tumors resulting in trauma to the hypothalamus and pituitary gland can also cause DI. Fluid and electrolyte balance must be closely monitored in these patients, and ADH replacement may be needed. The ADH preparations vasopressin (Pitressin) and desmopressin acetate (DDAVP) can be administered intranasally or by injection.

Nursing Process
Patient-Centered Collaborative Care

Pituitary Hormones

Assessment

- Obtain baseline vital signs for future comparison. Report abnormal results.
- Determine patient's urinary output and weight.

- Assess patient for an infectious process. Corticotropin can suppress signs and symptoms of infection.
- Note patient's physical growth. Compare child's growth with reported standards. Report findings.

Nursing Diagnoses

- Ineffective health maintenance related to lack of ability to maintain drug regimen
- Delayed growth and development related to deficient stimulation of growth hormone
- Deficient knowledge related to inexperience with medication regimen

Planning

- Patient will be free from pituitary disorder with appropriate drug regimen.

Nursing Interventions

Antidiuretic Hormone (ADH)

- Monitor vital signs. Increased heart rate and decreased systolic pressure can indicate fluid volume loss resulting from decreased ADH production. With less ADH secretion, more water is excreted, decreasing vascular fluid (hypovolemia).
- Record urinary output. Increased output can indicate fluid loss caused by a decrease in ADH.

Repository Corticotropin

- Avoid administering corticotropin to patients with adrenocortical hyperfunction. Corticotropin stimulates the release of cortisol from the adrenal glands.
- Monitor the growth and development of a child receiving corticotropin.
- Observe patient's weight. Check for edema if weight gain occurs. A side effect of repository corticotropin is sodium and water retention.
- Watch carefully for adverse effects when corticotropin is discontinued. Dose should be tapered and not stopped abruptly, because adrenal hypofunction may result.
- Check laboratory findings, especially electrolyte levels. Electrolyte replacement may be necessary.

Growth Hormone (GH)

- Monitor blood sugar and electrolyte levels in patients receiving GH. Hyperglycemia can occur with high doses.

Patient Teaching

Adrenocorticotropic Hormone (ACTH)

- Advise patient to adhere to drug regimen. Discontinuation of certain drugs, such as corticotropin, can cause hypofunction of gland being stimulated.
- Direct patient to decrease salt intake to decrease or avoid edema. Potassium supplement may be needed.
- Teach patient to report side effects such as muscle weakness, edema, petechiae, ecchymosis, decrease in growth, decreased wound healing, and menstrual irregularities.

Growth Hormone (GH)

- Advise athletes not to take GH because of side effects. GH can be effective for children whose height is markedly below expected norm for their age. Because GH acts on newly forming bone, administer before epiphyses are fused.
- Inform patient with diabetes to closely monitor blood sugar levels. Insulin regulation may be necessary.
- Suggest that patient or family monitor patient's growth rate.

Cultural Considerations

- Individuals in some cultural groups may misunderstand purpose and use of GH. Health care provider needs to emphasize that these are not drugs for building muscles and that they can cause many serious side effects, such as diabetes mellitus, when abused.

Evaluation

- Evaluate effectiveness of drug therapy.

When there is excess secretion of ADH from the posterior pituitary gland, the most common cause is small cell carcinoma of the lung. Medications, other malignancies, and stressors (e.g., pain, infection, anxiety, trauma) may also be causative factors. These conditions lead to an excessive amount of water retention expanding the intracellular volume. This increased fluid volume causes enhanced glomerular filtration and decreased tubular sodium reabsorption. Natriuresis (excretion of urinary sodium) results, leading to hyponatremia.

SIADH can be treated by fluid restriction, demeclocycline, conivaptan, and tolvaptan. Serum sodium levels must be monitored closely. Table 51-1 lists the drugs used for pituitary disorders and their dosages, uses, and considerations.

THYROID GLAND

Thyroxine (T_4) and **triiodothyronine** (T_3) are secreted by the thyroid gland. The functions of T_4 and T_3 are to regulate protein synthesis and enzyme activity and to stimulate mitochondrial oxidation. Approximately 20% of circulating T_3 is secreted from the thyroid gland, and 80% of T_3 comes from the degradation of about 40% of T_4, which occurs in the periphery. T_4 and T_3 are carried in the blood by thyroxine-binding globulin (TBG) and albumin, which protect the hormones from being degraded. T_3 is more potent than T_4, and only unbound free T_3 and T_4 are active and produce a hormonal response.

Feedback mechanisms regulate T_4 and T_3 secretion from the thyroid gland. The hypothalamus releases thyrotropin-releasing hormone (TRH), which stimulates the release of TSH from the pituitary gland. TSH stimulates the synthesis and release of T_4 and T_3 from the thyroid gland. Excess free T_4 and T_3 inhibit the hypothalamus-pituitary-thyroid (HPT) axis, which results in decreased TRH and TSH secretion. Likewise, too low an amount of T_4 and T_3 increases the function of the HPT axis.

For thyroid deficiency (hypothyroidism), synthetic T_4 and T_3 may be prescribed, either alone or in combination. When the thyroid gland secretes an overabundance of thyroid hormones (hyperthyroidism), antithyroid drugs are usually indicated.

Hypothyroidism

Hypothyroidism, a decrease in thyroid hormone secretion, can have either a primary cause (thyroid gland disorder) or a secondary cause (lack of TSH secretion). Primary hypothyroidism occurs more frequently. Decreased T_4 and elevated TSH levels indicate primary hypothyroidism, the causes of which are acute or chronic inflammation of the thyroid gland, radioiodine therapy, excess intake of antithyroid drugs, and surgery. **Myxedema** is severe hypothyroidism in the adult; symptoms include lethargy, apathy, memory impairment, emotional changes, slow speech, deep coarse voice, edema of the eyelids and face, dry skin, cold intolerance, slow pulse, constipation, weight gain, and abnormal menses. In children, hypothyroidism can have a congenital (**cretinism**) or prepubertal (juvenile hypothyroidism) onset. Drugs containing T_4 and T_3, alone or in combination, are used to treat hypothyroidism.

Drug Therapy: Hypothyroidism

Levothyroxine sodium (Synthroid) is the drug of choice for replacement therapy for the treatment of hypothyroidism. It increases the levels of T_3 and T_4. Levothyroxine is also used to treat simple goiter and chronic lymphocytic (Hashimoto) thyroiditis.

Liothyronine (Cytomel) is a synthetic T_3 that has a short half-life and duration of action; it is not recommended for maintenance therapy. Liothyronine is better absorbed from the GI tract than levothyroxine, and because of its rapid onset of action and short half-life, it is frequently used as initial therapy for treating myxedema.

Liotrix (Thyrolar) is a mixture of levothyroxine sodium and liothyronine sodium in a 4 : 1 ratio. For treating hypothyroidism, there is no significant advantage to using liotrix over levothyroxine sodium alone, because levothyroxine converts T_4 to T_3 in the peripheral tissues.

Prototype Drug Chart 51-2 lists the pharmacologic data for levothyroxine.

PROTOTYPE DRUG CHART 51-2

Levothyroxine Sodium

Drug Class Thyroid hormone Trade Names: T_4, Synthroid Pregnancy Category: A	**Dosage** A: PO: Initially: 25-50 mcg/d; maint: 50-200 mcg/d; A: IV: 50-100 mcg/d C: >12 y: PO: 2-3 mcg/kg/d
Contraindications Thyrotoxicosis, myocardial infarction, severe renal disease, adrenal insufficiency Caution: Cardiovascular disease, hypertension, angina pectoris, diabetes mellitus, osteoporosis	**Drug-Lab-Food Interactions** Drug: Increase cardiac insufficiency with epinephrine; increase effects of anticoagulants, tricyclic antidepressants, vasopressors, decongestants; decrease effects of antidiabetics (oral and insulin), digitalis products; decrease absorption with estrogens, antacids, cholestyramine, colestipol; increase risk of digitalis toxicity Food: Should be taken on an empty stomach, t½-1 h before eating
Pharmacokinetics Absorption: PO: 50%-75% Distribution: PB: 99% Metabolism: t½: 6-7 days Excretion: In bile and feces	**Pharmacodynamics** PO: Onset: UK Peak: 24 h-1 wk Duration: 1-3 wk IV: Onset: 6-8 h Peak: 24-48 h Duration: UK
Therapeutic Effects/Uses To treat hypothyroidism, myxedema, and cretinism Mode of Action: Increases metabolic rate, oxygen consumption, and body growth	
Side Effects Nausea, vomiting, anorexia, diarrhea, cramps, tremors, nervousness, irritability, insomnia, headache, weight loss, diaphoresis, amenorrhea	**Adverse Reactions** Tachycardia, hypertension, palpitations, osteoporosis, seizures Life-threatening: Thyroid crisis, angina pectoris, cardiac dysrhythmias (atrial fibrillation), cardiovascular collapse

A, Adult; *C,* child; *d,* day; *h,* hour; *IV,* intravenous; *maint,* maintenance; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *wk,* week; *y,* year; *>,* greater than.

Pharmacokinetics Levothyroxine (T_4) is a synthetic thyroid hormone preparation. The GI mucosa absorbs 50% to 75% of levothyroxine. It is highly protein-bound, and when administered with other highly protein-bound drugs like oral anticoagulants, side effects can result. The half-life of levothyroxine is longer than that of liothyronine. Levothyroxine is excreted in the bile and feces.

Pharmacodynamics Levothyroxine increases metabolic rate, cardiac output, protein synthesis, and glycogen use. The peak concentration time and duration of action are much longer with levothyroxine than with liothyronine. Liotrix is a combination of T_4 and T_3 with a greater concentration of T_4.

Drug Interactions. Many drug interactions are associated with T_4 and T_3 drugs. Thyroid preparations increase the effect of oral anticoagulants because of drug displacement from the protein-binding sites. When these thyroid replacement drugs are taken with an adrenergic agent (e.g., decongestant or vasopressor), the cardiac and central nervous system (CNS) actions are increased. Levothyroxine and liothyronine can decrease the effectiveness of digitalis preparations. Estrogen can increase the effect of liothyronine. Insulin and oral antidiabetic drug dosages may need to be increased.

Table 51-2 lists the natural and synthetic thyroid preparations and their dosages, uses, and considerations.

Hyperthyroidism

Hyperthyroidism is an increase in circulating T_4 and T_3 levels, which usually results from an overactive thyroid gland or excessive output of thyroid hormones from one or more thyroid nodules. Hyperthyroidism may be mild with few symptoms or severe, as in thyroid storm in which death may occur from vascular collapse. **Graves' disease,** or **thyrotoxicosis,** is the most common type of hyperthyroidism caused by hyperfunction of the thyroid gland. It is characterized by a rapid pulse *(tachycardia)*, palpitations, excessive perspiration, heat intolerance, nervousness, irritability, exophthalmos (bulging eyes), and weight loss.

Hyperthyroidism can be treated by surgical removal of a portion of the thyroid gland (subtotal thyroidectomy), radioactive iodine therapy, or antithyroid drugs, which inhibit either synthesis or release of thyroid hormone. Any of these treatments can cause hypothyroidism. Propranolol (Inderal) can control cardiac symptoms like palpitations and tachycardia that result from hyperthyroidism. It does not lower T_4 and T_3.

TABLE 51-2 THYROID HORMONE: REPLACEMENTS AND ANTITHYROID DRUGS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Thyroid Replacements: Hypothyroidism		
levothyroxine sodium (Synthroid)	See Prototype Drug Chart 51-2.	
liothyronine sodium (Cytomel)	A: PO: Initially: 5-25 mcg/d; maint: 25-75 mcg/d C: PO: Initially: 5 mcg/d; >3 y: 25-75 mcg/d	For hypothyroidism. Synthetic T_3 drug. Faster acting than other thyroid drugs. Effects seen in 24-72 h. Cardiac side effects. Pregnancy category: A; PB: 99%; t½: 2.5 d
liotrix (Thyrolar)	A/C: PO: Initially: 50-100 mcg/d	For hypothyroidism. Synthetic T_4 and T_3 drug; 4 : 1 ratio. Common side effects include irritability, nervousness, insomnia, tachycardia, and weight loss. Pregnancy category: A; PB: 99%; t½: <7 d
thyroid (Armour, Thyrotab)	A: PO: Initially: 15-30 mg/d; maint: 60-120 mg/d C: >6 mo: PO: maint: 30-90 mg/d	For hypothyroidism to reduce goiter size. Natural form obtained from animals. T_4 and T_3: 4 : 1 ratio. Common side effects include irritability, nervousness, insomnia, tachycardia, and weight loss. Pregnancy category: A; PB: 99%; t½: <7 d (T_3: 1-2 h; T_4: 6-7 d)
Antithyroid Drugs: Hyperthyroidism		
Thioamides		
methimazole (Tapazole)	A: PO: 15-60 mg/d in 1-3 divided doses C: PO: 0.2-0.4 mg/kg/d in 1-3 divided doses	For hyperthyroidism. Inhibits thyroid hormone synthesis. Onset of action: 1 wk for effect. Rash, urticaria, headache, and GI upset may occur. Pregnancy category: D; PB: 0%; t½: 5-9 h
propylthiouracil (PTU)	A: PO: Initially 300 mg/d divided q8h; then 100-150 mg/d divided q8h C: >6 y: PO: 50-150 mg/d in divided doses	For hyperthyroidism, Graves' disease. Inhibits conversion of T_4 and T_3. May be used before surgery or radioactive iodine treatment and for palliative control of toxic goiter. May cause severe liver damage, liver failure, and death. Pregnancy category: D; PB: 80%; t½: 1-5 h
Iodine		
potassium iodide (SSKI)	A/C: PO: 250 mg t.i.d. for 10-14 d before surgery	For hyperthyroidism. To reduce size and vascularity of thyroid gland. Dilute drug and administer after meals; sip through straw to avoid discoloration of teeth. Maximum effect after 10-15 days. Pregnancy category: D; PB: UK; t½: UK

A, Adult; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *maint,* maintenance; *PB,* protein-binding; *p.c.,* after meals; *PO,* by mouth; *t½*, half-life; *T_4*, thyroxine; *T_3*, triiodothyronine; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week; *y,* year; *>,* greater than; *<,* less than.

Drug Therapy: Hyperthyroidism

The purpose of antithyroid drugs is to reduce the excessive secretion of thyroid hormones (T_4 and T_3) by inhibiting thyroid secretion. The use of surgery (subtotal thyroidectomy) and radioiodine therapy frequently leads to hypothyroidism. Thiourea derivatives (thioamides) are the drugs of choice used to decrease thyroid hormone production. This drug group interferes with synthesis of thyroid hormone. Thiourea derivatives do not destroy thyroid tissue, but rather block thyroid hormone action.

Propylthiouracil (PTU) and methimazole (Tapazole) are effective thioamide antithyroid drugs. They are useful for treating thyrotoxic crisis and in preparation for subtotal thyroidectomy. Methimazole does not inhibit peripheral conversion of T_4 to T_3 as does PTU; however, it is 10 times more potent and it has a longer half-life than PTU. Prolonged use of thioamides may cause goiter because of increased TSH secretion and inhibited T_4 and T_3 synthesis. Minimal doses of thioamides should be given when indicated to avoid goiter formation.

Strong iodide preparations such as potassium iodide have been used to suppress thyroid function for patients who have undergone subtotal thyroidectomy as a result of Graves' disease. Table 51-2 lists the antithyroid drugs used to treat hyperthyroidism and their dosages, uses, and considerations.

Drug Interactions. Antithyroid drugs interact with many other drugs. When used with oral anticoagulants (e.g., warfarin [Coumadin]), they can cause an increase in the anticoagulation effect. In addition, thyroid drugs decrease the effect of insulin and oral antidiabetics; digoxin and lithium increase the action of thyroid drugs; and phenytoin (Dilantin) increases serum T_3 level.

PARATHYROID GLANDS

The parathyroid glands secrete **parathyroid hormone** (PTH), which regulates calcium levels in the blood. A decrease in serum calcium stimulates the release of PTH. Calcitonin decreases serum calcium levels by promoting renal excretion of calcium. The functions of PTH and calcitonin are discussed in the introduction to Unit XVII.

Hypoparathyroidism

Parathyroid hormone agents treat hypoparathyroidism. Hypocalcemia (serum calcium deficit) can be caused by PTH deficiency, vitamin D deficiency, renal impairment, or diuretic therapy, and PTH replacement helps correct the calcium deficit. The action of PTH is to promote calcium absorption from the GI tract, promote reabsorption of calcium from the renal tubules, and activate vitamin D.

Calcitriol

Calcitriol is a vitamin D analogue that promotes calcium absorption from the GI tract and secretion of calcium from bone to the bloodstream. Prototype Drug Chart 51-3 lists the pharmacologic data for calcitriol.

PROTOTYPE DRUG CHART 51-3

Calcitriol

Drug Class Vitamin D analogue Trade Name: Rocaltrol Pregnancy Category: C	**Dosage** A/C: >6 y: PO: 0.25 mcg/d
Contraindications Hypersensitivity, hypercalcemia, hypervitaminosis D, malabsorption syndrome Caution: Cardiovascular disease, renal calculi, renal failure, hyperphosphatemia, dehydration, excess sunlight exposure	**Drug-Lab-Food Interactions** Drug: Increase cardiac dysrhythmias with digoxin, verapamil; decrease calcitriol absorption with cholestyramine Lab: Increase serum calcium with thiazide diuretics, calcium supplements
Pharmacokinetics Absorption: PO: Well absorbed Distribution: PB: UK; crosses placenta Metabolism: t½: 3-8 h Excretion: Mostly in feces	**Pharmacodynamics** PO: Onset: 2-6 h Peak: 10-12 h Duration: 3-5 d
Therapeutic Effects/Uses To treat hypoparathyroidism and manage hypocalcemia in chronic renal failure Mode of Action: Enhances calcium deposits in bones	
Side Effects Anorexia, nausea, vomiting, diarrhea, cramps, drowsiness, headache, dizziness, vertigo, metallic taste, lethargy, photophobia	**Adverse Reactions** Hypercalciuria, hypercalcemia, hyperphosphatemia, hematuria

A, Adult; *d,* day; *h,* hour; *PB,* protein binding; *PO,* by mouth; *t ½,* half-life; *UK,* unknown.

Pharmacokinetics Calcitriol is readily absorbed from the GI tract. Its half-life is moderate (3 to 8 hours). Most of the drug is excreted in feces.

Pharmacodynamics Calcitriol is given for the management of hypocalcemia. It increases serum calcium levels by promoting calcium absorption from the intestines and renal tubules. Calcitriol has a long onset of action, peak action, and duration of action.

Nursing Process
Patient-Centered Collaborative Care

Thyroid Hormone: Replacement and Antithyroid Drugs

Assessment

- Determine baseline vital signs for future comparison. Report abnormal results.
- Check serum T_3, T_4, and TSH levels. Report abnormal results.

Thyroid Replacement

- Obtain history of drugs patient currently takes. Be aware that thyroid drugs enhance action of oral anticoagulants, sympathomimetics, and antidepressants and decrease action of insulin, oral hypoglycemics, and digitalis preparations. Phenytoin and aspirin can enhance action of thyroid hormone.

Antithyroid Drugs

- Assess for signs and symptoms of thyroid crisis (thyroid storm), including tachycardia, cardiac dysrhythmias, fever, heart failure, flushed skin, apathy, confusion, behavioral changes, and later hypotension and vascular collapse. Thyroid crisis can result from a thyroidectomy (excess thyroid hormones released), abrupt withdrawal of antithyroid drug, excess ingestion of thyroid hormone, or failure to give antithyroid medication before thyroid surgery.

Nursing Diagnoses

- Ineffective health maintenance related to inability to maintain drug regimen
- Ineffective peripheral tissue perfusion related to hyposecretion of thyroid hormone
- Activity intolerance related to generalized weakness
- Deficient knowledge related to inexperience with thyroid medication regimen

Planning

- Patient's signs and symptoms of hypothyroidism will be alleviated within 2 to 4 weeks with prescribed thyroid drug replacement, and patient will not experience side effects.
- Patient's signs and symptoms of hyperthyroidism will be alleviated in 1 to 3 weeks with prescribed antithyroid drug.

Nursing Interventions

- Record vital signs. With hypothyroidism, temperature, heart rate, and blood pressure usually decrease. With hyperthyroidism, tachycardia and palpitations usually occur.
- Monitor patient's weight. Weight gain commonly occurs in patients with hypothyroidism.

Patient Teaching

Thyroid Drug Replacement

- Encourage patient to take drug at same time each day, preferably before breakfast. Food will hamper absorption rate.
- Teach patient to check warnings on OTC drug labels. Avoid OTC drugs that caution against use by persons with heart or thyroid disease.
- Direct patient to report symptoms of hyperthyroidism (tachycardia, chest pain, palpitations, excess sweating) caused by drug accumulation or overdosing.
- Suggest that patient carry MedicAlert identification card, tag, or bracelet with condition and drug used.

Diet: Hypothyroidism

- Caution patient to avoid foods that can inhibit thyroid secretion (strawberries, peaches, pears, cabbage, turnips, spinach, kale, brussels sprouts, cauliflower, radishes, peas).

Antithyroid Drugs for Hyperthyroidism

- Teach patient to take drug with meals to decrease gastrointestinal symptoms.
- Advise patient about effects of iodine and its presence in iodized salt, shellfish, and OTC cough medicines.
- Emphasize importance of drug compliance; abruptly stopping antithyroid drug could bring on thyroid crisis.
- Teach patient signs and symptoms of hypothyroidism: lethargy, puffy eyelids and face, thick tongue, slow speech with hoarseness, lack of perspiration, and slow pulse. Hypothyroidism can result from treatment of hyperthyroidism.
- Advise patient to avoid antithyroid drugs if pregnant or breastfeeding. Antithyroid drugs taken during pregnancy can cause hypothyroidism in fetus or infant.

Self-Administration

- Demonstrate to patient how to take pulse rate. Instruct patient to monitor pulse rate and report increases or marked decreases in rate.

Side Effects

- Teach patient side effects of antithyroid drugs: skin rash, hives, nausea, alopecia, loss of hair pigment, petechiae or ecchymoses, and weakness.

- Advise patient to contact health care provider if sore throat and fever occur while taking antithyroid drugs. A serious adverse reaction of antithyroid drugs is agranulocytosis (loss of white blood cells). Complete blood count should be monitored for leukopenia.

Cultural Considerations

- Recognize that members of various cultural groups may need guidance in understanding disease process of hypothyroidism or hyperthyroidism. Support patients and family members, who may lack knowledge of prescribed drug therapy for management of thyroid condition. Additional time in explanations and written plan of care may be necessary for non–English-speaking persons.

Evaluation

Thyroid Replacement

- Evaluate effectiveness of thyroid drug and drug compliance.
- Continue monitoring for side effects from drug accumulation or overdosing.
- Evaluate patient's knowledge of medication regimen.

Antithyroid Drugs

- Evaluate effectiveness of antithyroid drug in decreasing signs and symptoms of hyperthyroidism. If signs and symptoms persist after 2 to 3 weeks of therapy, other methods for correcting hyperthyroidism may be necessary.

Hyperparathyroidism

Hyperparathyroidism can be caused by malignancies of the parathyroid glands or ectopic PTH hormone secretion from lung cancer, hyperthyroidism, or prolonged immobility, during which calcium is lost from bone. Synthetic calcitonin treats hyperparathyroidism. Table 51-3 lists the drugs used to treat hypoparathyroidism and hyperparathyroidism and their dosages, uses, and considerations.

ADRENAL GLANDS

The paired **adrenal glands** consist of the adrenal medulla and adrenal cortex. The adrenal cortex produces two types of hormones, or corticosteroids: glucocorticoids (cortisol) and mineralocorticoids (aldosterone). Cortisol is secreted by the adrenal glands in response to the hypothalamus-pituitary-adrenal (HPA) axis as a result of the feedback mechanism. A decrease in serum cortisol levels increases CRF and ACTH secretions, which stimulate the adrenal glands to secrete and release cortisol. An increased serum cortisol level exerts the negative feedback mechanism, which inhibits the HPA axis, resulting in less cortisol being released. Additional physiologic functions related to the hormones secreted from the adrenal medulla and adrenal cortex are described in the introduction to Unit XVII.

Corticosteroids promote sodium retention and potassium excretion. A sodium ion is reabsorbed from the renal tubule in exchange for a potassium ion; the potassium ion is then excreted. Because of their influence on electrolytes and carbohydrate, protein, and fat metabolism, a deficiency of corticosteroids can result in serious illness or death. A decrease in corticosteroid secretion is called *adrenal hyposecretion* (adrenal insufficiency, or **Addison's disease**), and an increase in corticosteroid secretion is called *adrenal hypersecretion* (**Cushing's syndrome**).

TABLE 51-3 DRUG THERAPIES FOR PARATHYROID DISORDERS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Treatment for Hypoparathyroidism and Hypocalcemia: Vitamin D Analogues		
calcitriol (Rocaltrol)	See Prototype Drug Chart 51-3.	
ergocalciferol (Drisdol)	Hypoparathyroidism: A/C: PO: 1250-5000 mcg/d	For hypoparathyroidism and rickets. Enhances calcium and phosphorus absorption. Long duration of action. Pregnancy category: C; PB: UK; t½: 12-24 h
Treatment for Hyperparathyroidism and Hypercalcemia		
calcitonin-salmon (Miacalcin, Fortical)	Hyercalcemia: A: 200 units in 1 nostril/d, alternate nostrils	For Paget's disease (osteitis deformans), hyperparathyroidism, and hypercalcemia. Calcitonin decreases serum calcium by binding at receptor sites on osteoclast. Pregnancy category: C; PB: UK; t½: 1-1.5 h
etidronate	A: PO: 5-10 mg/kg/d; *max:* 20 mg/kg/d	For Paget's disease; for hypercalcemia caused by antineoplastic therapy. Pregnancy category: C; PB: UK; t½: 6 h
cinacalcet (Sensipar)	A: PO: Initially 30 mg/d; titrate individualized dose q2-4wk	For hyperparathyroidism and hypercalcemia. Pregnancy category: C; PB: 93%-97%; t½: 30-40 h

A, Adult; *b.i.d.,* two times a day; *C,* child; *d,* day; *h,* hour; *IM,* intramuscular; *maint,* maintenance; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *subQ,* subcutaneous; *t½,* half-life; *UK,* unknown; *wk,* week.

Nursing Process

Patient-Centered Collaborative Care

Parathyroid Hormone Insufficiencies

Assessment

- Note serum calcium level. Report abnormal results.
- Assess for symptoms of tetany in hypocalcemia: twitching of mouth, tingling and numbness of fingers, carpopedal spasm, spasmodic contractions, and laryngeal spasm.

Nursing Diagnoses

- Diarrhea related to adverse effects of calcitriol
- Deficient fluid volume related to fluid loss from vomiting and polyuria
- Deficient knowledge related to inexperience with parathyroid medication

Planning

- Patient's serum calcium level will be within normal range.

Nursing Interventions

- Monitor serum calcium level. Normal reference value is 4.5 to 5.5 mg/dL (ionized or free-flowing calcium in the blood) or 8 to 10 mg/dL (total calcium, including free-flowing calcium or calcium bound to albumin). Serum calcium <4.5 mg/dL or <8 mg/dL indicates hypocalcemia. Total serum calcium >10.5 mg/dL or ionized calcium >5.5 mg/dL indicates hypercalcemia. Serum ionized calcium levels are usually used because much of the calcium is protein-bound, non-ionized, and nonactive.

Patient Teaching

Hypoparathyroidism

- Direct patient to report symptoms of tetany (see Assessment).

Hyperparathyroidism

- Teach patient to report signs and symptoms of hypercalcemia: bone pain, anorexia, nausea, vomiting, thirst, constipation, lethargy, bradycardia, and polyuria.
- Advise women to inform health care provider about pregnancy status before taking calcitonin preparation.
- Encourage patient to check OTC drugs for possible calcium content, especially if patient has elevated serum calcium level. Some vitamins and antacids contain calcium. Tell patient to contact health care provider before taking drugs with calcium.

Cultural Considerations

- Obtain interpreter when necessary; do not rely on family members, who may not fully disclose because of cultural norms.
- Identify conflicts in values and beliefs, and engage in culturally sensitive patient dialogue and education.

Evaluation

- Monitor effectiveness of drug therapy.
- Continue monitoring for signs and symptoms of hypocalcemia (tetany) when commercially prepared calcitonin has been given.
- Evaluate patient's knowledge of medication regimen.

Glucocorticoids

Glucocorticoids are influenced by ACTH, which is released from the anterior pituitary gland. They affect carbohydrate, protein, and fat metabolism and muscle and blood cell activity. Because of their many mineralocorticoid effects, glucocorticoids can cause sodium absorption from the kidney, resulting in water retention, potassium loss, and increased blood pressure. Cortisol, the main glucocorticoid, has antiinflammatory, antiallergic, and antistress effects. Indications for glucocorticoid therapy include trauma, surgery, inflammation, emotional upsets, and anxiety. Table 51-4 lists the physiologic aspects of adrenal hyposecretion (Addison's disease) and hypersecretion (Cushing's syndrome).

Most of the wide variety of glucocorticoid drugs, frequently called *cortisone drugs,* is synthetically produced. These drugs have several routes of administration: oral, parenteral (IM or IV), topical (creams, ointments, lotions), and

TABLE 51-4 **PHYSIOLOGIC DATA: ADRENAL HYPOSECRETION AND HYPERSECRETION**

BODY SYSTEM	ADRENAL HYPOSECRETION	ADRENAL HYPERSECRETION
Metabolism		
Glucose	Hypoglycemia	Hyperglycemia
Protein	Muscle weakness	Muscle wasting; thinning of skin; poor wound healing; osteoporosis;
Fat		fat accumulation in face (moon face), back of neck (buffalo hump), and trunk (protruding abdomen); hyperlipidemia; high cholesterol
Central nervous system	Apathy, depression, fatigue	Increased neural activity; mood elevation; irritability; seizures
Gastrointestinal	Nausea, vomiting, abdominal pain	Peptic ulcers
Cardiovascular	Tachycardia, hypotension, cardiovascular collapse	Hypertension; edema; heart failure
Eyes	None	Cataract formation
Fluids and electrolytes	Hypovolemia; hyponatremia; hyperkalemia	Hypervolemia; hypernatremia; hypokalemia
Blood cells	Anemia	Increased red blood cell count and neutrophils; impaired clotting

aerosol (inhaler). The IM route, although seldom used, should be administered deep into the muscle. The subQ route is not recommended.

Glucocorticoids are used to treat many diseases and health problems, including inflammatory, allergic, and debilitating conditions. Among the inflammatory conditions that may require glucocorticoids are autoimmune disorders (e.g., multiple sclerosis, rheumatoid arthritis, myasthenia gravis); ulcerative colitis; glomerulonephritis; shock; ocular and vascular inflammations; polyarteritis nodosa; and hepatitis. Allergic conditions include asthma, drug reactions, contact dermatitis, and anaphylaxis. Debilitating conditions are mainly caused by malignancies. Organ transplant recipients may require glucocorticoids to prevent organ rejection.

There are many glucocorticoids, some more potent than others. Dexamethasone (Decadron) has been used to treat severe inflammatory response resulting from head trauma or allergic reactions. An inexpensive glucocorticoid frequently prescribed is prednisone. Prototype Drug Chart 51-4 lists the pharmacologic data for prednisone.

Pharmacokinetics Prednisone is readily absorbed from the GI tract. It has a short half-life of 3 to 4 hours, and it has a moderately high protein-binding power. Prednisone is excreted primarily in the urine.

Pharmacodynamics The major actions of prednisone are to suppress an sacute inflammatory process and for immunosuppression. It prevents cell-mediated immune reactions. Peak action occurs in 1 to 2 hours, and its duration of action is long (1 to 1.5 days).

Commonly used glucocorticoid drugs are listed in Table 51-5. Most of the glucocorticoids are pregnancy category C drugs. Agents used for adrenocortical insufficiency contain both glucocorticoids and mineralocorticoids, whereas drugs for antiinflammatory or immunosuppressive use contain mostly glucocorticoids.

Side Effects and Adverse Reactions. The side effects and adverse reactions of glucocorticoids that result from high doses or prolonged use include increased blood sugar, abnormal fat deposits in the face and trunk (so-called *moon face* and *buffalo hump*), decreased extremity size, muscle wasting, edema, sodium and water retention, hypertension, euphoria or psychosis, thinned skin with purpura, increased intraocular pressure (glaucoma), peptic ulcers, and growth retardation. Long-term use of glucocorticoid drugs can cause adrenal atrophy (loss of adrenal gland function). When drug therapy is discontinued, the dose should be tapered to allow the adrenal cortex to produce cortisol and other corticosteroids. Abrupt withdrawal of the drug can result in severe adrenocortical insufficiency.

Drug Interactions. Glucocorticoids increase the potency of drugs taken concurrently, including aspirin and nonsteroidal antiinflammatory drugs (NSAIDs), thus increasing the risk of GI bleeding and ulceration. Use of potassium-wasting diuretics (e.g., Lasix) with glucocorticoids increases potassium loss, resulting in hypokalemia.

PROTOTYPE DRUG CHART 51-4

Prednisone

Drug Class Adrenal hormone: glucocorticoid Trade Name: Deltasone Pregnancy Category: C	**Dosage** A: PO: 5-60 mg/d in single or divided doses C: PO: 0.1-0.15 mg/kg/d in single or divided doses
Contraindications Hypersensitivity, psychosis, fungal infection, peptic ulcer disease Caution: Diabetes mellitus, renal disease, HF, MI, hypertension, osteoporosis, seizures, cataracts, glaucoma	**Drug-Lab-Food Interactions** Drug: Increase effect with estrogens, diltiazem, ketoconazole; decrease effects with barbiturates, phenytoin, rifampin. Concurrent use of aspirin and NSAIDs increase GI toxicity; concurrent use of diuretics and amphotericin B increase K depletion; concurrent use with cardiac glycosides increases risk of dysrhythmias and digitalis toxicity
Pharmacokinetics Absorption: PO: Well absorbed Distribution: PB: 70%-90%; crosses placenta Metabolism: t½: 3.5 h Excretion: In urine	**Pharmacodynamics** PO: Onset: UK Peak: 1-2 h Duration: 24-36 d
Therapeutic Effects/Uses To decrease inflammatory occurrence; as an immunosuppressant; to treat dermatologic disorders Mode of Action: Suppresses inflammation and adrenal function	
Side Effects Nausea, diarrhea, abdominal distention, increased appetite, sweating, headache, depression, flushing, mood changes, cataracts, amenorrhea	**Adverse Reactions** Petechiae, ecchymosis, hypertension, tachycardia, osteoporosis, muscle wasting, sodium and fluid retention Life-threatening: GI hemorrhage, pancreatitis, circulatory collapse, thrombophlebitis, embolism

A, Adult; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *PB,* protein-binding; *PO,* by mouth; *t ½,* half-life; *UK,* unknown.

TABLE 51-5 ADRENAL HORMONES: GLUCOCORTICOIDS, MINERALOCORTICOID, AND GLUCOCORTICOID INHIBITORS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Glucocorticoids		
Short Acting		
cortisone acetate	A: PO: 10-37.5 mg/d	For adrenocortical insufficiency. Contains glucocorticoid and mineralocorticoid. Decreases inflammatory process. Oral dose rapidly absorbed from GI tract. Administer deep IM. Give oral dose with food. Pregnancy category: D; PB: UK; t½: 8-12 h
hydrocortisone (Cortef, Hydrocortone)	A: PO: 20-240 mg/d in 3-4 divided doses IV: 15-500 mg/d Rectal supp: 10-25 mg	For adrenocortical insufficiency and inflammation. Parenteral form: hydrocortisone sodium phosphate. Acetate form of drug may be injected into joints. Available in cream, ointment, lotion, and spray. Pregnancy category: C; PB: 79%; t½: 1.5-2 h
Intermediate Acting		
methylprednisolone (Solu-Medrol, Depo-Medrol)	A: PO: 2-60 mg/d in 1 or more divided doses A: IV: Succinate: 10-80 mg/d IM: Acetate: 10-80 mg/wk	For inflammatory conditions such as arthritis, bronchial asthma, allergic reactions, and cerebral edema. Pregnancy category: C; PB: UK; t½: 18-36 h
prednisolone (AK-Pred)	A: PO: 5-60 mg/d C: PO: 0.1-2 mg/kg/d in divided doses	For antiinflammatory or immunosuppressive effect. For parenteral use. Can be injected into joints and soft tissue. Potent steroid. Pregnancy category: C; PB: 65%-90%; t½: 3.5 h
prednisone (Deltasone)	See Prototype Drug Chart 51-4.	
Long Acting		
beclomethasone dipropionate (Qvar, Beclovent, Vanceril)	A: Inhal: 1-2 puffs b.i.d.	Inhalation for bronchial asthma, bronchial inflammation, and seasonal rhinitis. Like all glucocorticoid inhalants, for prophylactic use. Not for acute asthmatic attack. Pregnancy category: C; PB: 87%; t½: 15 h
betamethasone (Celestone)	A: PO: 0.6-7.2 mg/d in single or divided doses IM/IV: 1-9 mg/d; *max:* IM: 12 mg/d	Potent antiinflammatory steroid drug. May be injected into joints. Also effective for treating bronchial asthma, arthritis, severe allergic reactions, and cerebral edema. Should be taken with food. Pregnancy category: C; PB: 64%; t½: 35-54 h
dexamethasone (Decadron)	Inflammation: A: PO: 0.75-9 mg/d in 2-4 divided doses C: PO: 0.024-0.34 mg/kg/d in divided doses A: IV/IM: 0.5-9 mg/d in 2-4 divided doses	Potent antiinflammatory drug. For acute allergic disorders, asthma attack, cerebral edema, and unresponsive shock. For diagnosis of Cushing's syndrome and depression. Can be administered IV push or in IV fluids. Give oral dose with food. Pregnancy category: C; PB: 80%-90%; t½: 3-4.5 h
Mineralocorticoids		
fludrocortisone (Florinef)	A: PO: 0.1-0.2 mg/d	For adrenocortical insufficiency, Addison's disease. Also for salt-losing adrenogenital syndrome. Used only for its mineralocorticoid effects. Pregnancy category: C; PB: 92%; t½:18-36 h
Diagnosis for Adrenal Gland Dysfunction		
corticotropin (Acthar)	Diagnostic test for adrenal and pituitary function	See Prototype Drug Chart 51-1.
cosyntropin (Cortrosyn)	Diagnostic test for adrenal and pituitary function	See Table 51-1.

A, Adult; *ACTH,* adrenocorticotropic hormone; *b.i.d.,* twice a day; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *inhal,* inhalation; *IV,* intravenous; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week.

Barbiturates, phenytoin, and rifampin decrease the effect of prednisone because they increase glucocorticoid metabolism. Larger doses of glucocorticoids may be required to achieve the desired effect. Prolonged use of prednisone can cause severe muscle weakness.

Dexamethasone, a potent glucocorticoid, interacts with many drugs. Phenytoin, theophylline, rifampin, barbiturates, and antacids decrease the action of dexamethasone, whereas NSAIDs, including aspirin, and estrogen increase its action. Dexamethasone decreases the effects of oral antidiabetics.

Glucocorticoids can increase blood sugar levels, so insulin or oral antidiabetic drug dosage may need to be increased. When the drug is given with diuretics or anti-*Pseudomonas* penicillin preparations, the serum potassium level may decrease markedly.

Mineralocorticoids

Mineralocorticoids, the second type of corticosteroid, secrete aldosterone. Aldosterone is controlled by the renin-angiotensin system, not by ACTH. These hormones maintain fluid balance by promoting the reabsorption of sodium from the renal tubules. Sodium attracts water, resulting in water retention. When *hypovolemia* (decrease in circulating fluid) occurs, more aldosterone is secreted to increase sodium and water retention and restore fluid balance. With sodium reabsorption, potassium is lost and hypokalemia (potassium deficit) can occur. Some glucocorticoid drugs also contain mineralocorticoids; these include cortisone and hydrocortisone. A severe decrease in the mineralocorticoid aldosterone leads to hypotension and vascular collapse, as seen in Addison's disease. Mineralocorticoid deficiency usually occurs with glucocorticoid deficiency, frequently called *corticosteroid deficiency.*

Fludrocortisone (Florinef) is an oral mineralocorticoid that can be given with a glucocorticoid. It can cause a negative nitrogen balance; therefore a high-protein diet is usually indicated. Because potassium excretion occurs with the use of mineralocorticoids and glucocorticoids, the serum potassium level should be monitored.

Nursing Process
Patient-Centered Collaborative Care

Adrenal Hormone: Glucocorticoids

Assessment

- Note baseline vital signs for future comparison.
- Assess laboratory test results, especially serum electrolytes and blood sugar. Serum potassium level usually decreases and blood sugar level increases when a glucocorticoid such as prednisone is taken over an extensive period.
- Obtain patient's weight and urine output for future comparison.
- Assess patient's medical and herbal history. Report if patient has glaucoma, cataracts, peptic ulcer, psychiatric problems, or diabetes mellitus. Glucocorticoids can intensify these health problems.

Nursing Diagnoses

- Deficient knowledge of drug discontinuation related to lack of recall
- Excess fluid volume related to fluid retention
- Risk for impaired skin integrity related to side effect of rash

Planning

- Patient's side effects of glucocorticoid therapy will be minimal.
- Patient's inflammatory process will decrease.
- Patient will have increased knowledge of medication regimen.

Nursing Interventions

- Determine vital signs. Glucocorticoids such as prednisone can increase blood pressure and sodium and water retention.
- Administer glucocorticoids only as ordered. Routes of administration include oral, IM (not in deltoid muscle), IV, aerosol, and topical. Apply topical glucocorticoids in thin layers. Rashes, infection, and purpura should be noted and reported.
- Record weight. Report weight gain of 5 lb in several days; this would most likely be caused by water retention.
- Monitor laboratory values, especially serum electrolytes and blood sugar. Serum potassium level could decrease to <3.5 mEq/L, and blood sugar level would probably increase.
- Watch carefully for signs and symptoms of hypokalemia: nausea, vomiting, muscular weakness, abdominal distention, paralytic ileus, and irregular heart rate.
- Assess for side effects from glucocorticoid drugs when therapy has lasted more than 10 days and drug is taken in high dosages. Cortisone preparation should not be abruptly stopped, because adrenal crisis can result.
- Monitor older adults for signs and symptoms of increased osteoporosis. Glucocorticoids promote calcium loss from bone.
- Report changes in muscle strength. High doses of glucocorticoids promote loss of muscle tone.

Patient Teaching

General

- Advise patient to take drug as prescribed. Caution patient not to abruptly stop drug. When drug is discontinued, dose is tapered over 1 to 2 weeks.
- Prepare schedule for patient to decrease dose over 4 to 5 days. For short-term use (<10 days) of glucocorticoids such as prednisone or other cortisone preparations, drug dose still needs to be tapered. For example, day 1: 1 tab four times a day; day 2: 1 tab three times a day; day 3: 1 tab twice a day; day 4: 1 tab once a day.
- Direct patient not to take cortisone preparations (oral or topical) during pregnancy unless necessary and prescribed by health care provider. Drugs may be harmful to fetus.
- Inform patient that certain herbal laxatives and diuretics may interact with glucocorticoid drug and may increase severity of hypokalemia (Herbal Alert 51-1).

- Teach patient to avoid persons with respiratory infections, because these drugs suppress immune system. This is especially important if patient is receiving high dose of glucocorticoids.
- Teach patient receiving glucocorticoids to inform other health care providers of all drugs taken, especially before surgery.
- Encourage patient to carry MedicAlert identification card, tag, or bracelet stating glucocorticoid taken.

Self-Administration

- Teach patient to use aerosol nebulizer. Warn patient against overuse of aerosol to avoid possible rebound effect.

Side Effects

- Teach patient to report signs and symptoms of drug overdose or Cushing's syndrome: moon face, puffy eyelids, edema in feet, increased bruising, dizziness, bleeding, and menstrual irregularity.

Diet

- Counsel patient to take cortisone preparations at mealtime or with food. Glucocorticoid drugs can irritate gastric mucosa and cause peptic ulcer.
- Advise patient to eat foods rich in potassium, such as fresh and dried fruits, vegetables, meats, and nuts. Prednisone promotes potassium loss and hypokalemia.

Cultural Considerations

- Recognize that members of various cultural groups may need guidance in understanding disease process of Cushing's syndrome. Explain to family that patient is not "dumb" or "uninterested" but has an adrenal problem. Explain that symptoms do not "go away" and may be progressive if prescribed therapy is not followed.

Evaluation

- Evaluate effectiveness of glucocorticoid therapy. If inflammation has not improved, change in drug therapy may be necessary.
- Continue monitoring for side effects, especially when patient is receiving high doses of glucocorticoids.
- Evaluate patient's knowledge of glucocorticoid therapy.

HERBAL ALERT 51-1

Herbs and Corticosteroids

- Herbal laxatives (cascara, senna) and herbal diuretics (celery seed, juniper) can decrease serum potassium levels. When these herbs are taken with corticosteroids, hypokalemia can become more severe.
- Ginseng taken with corticosteroids may cause central nervous system stimulation and insomnia.
- Echinacea may counteract the effects of corticosteroids.
- Licorice potentiates the effect of corticosteroids and may cause a substantial decrease in serum potassium level.

CRITICAL THINKING CASE STUDY

MP, a 68-year-old woman, had a severe allergic reaction to shellfish and was taken to the emergency department. A single dose of dexamethasone 100 mg IV (direct IV over 30 seconds) was ordered. MP weighs 65 kg.

1. Why is MP receiving dexamethasone IV? Is the dosage of dexamethasone within safe therapeutic range? Explain your answer.
2. Describe the various ways for administering dexamethasone IV. By what other routes can dexamethasone be administered?
3. What additional health information and assessment may aid the health care provider in treating MP's serious health problem?

Twenty-one tablets of prednisone, 5 mg each, were prescribed to be taken over 5 days, with tapering daily doses. The dosage is as follows: Day 1: take 10 mg four times a day; day 2: take 10 mg three times a day; day 3: take 10 mg twice a day; day 4: take 10 mg once a day; and day 5: take 5 mg once a day.

4. Why was prednisone ordered and not oral dexamethasone? Explain your answer.
5. What is the purpose for tapering prednisone doses? Explain your answer.
6. Is the drug dose within safe therapeutic range? Explain your answer.
7. Should MP have side effects such as peripheral edema caused by water and sodium retention as a result of tapered prednisone doses? Explain your answer.
8. What is the difference between prednisone and prednisolone?
9. What are the adverse reactions from prolonged use of prednisone?
10. What are the nursing interventions and patient teaching for MP and for patients who take prednisone?

NCLEX STUDY QUESTIONS

1. A patient is receiving the drug somatropin (Genotropin). The nurse understands that the action of this drug is to do what?
   a. Act as an antiinflammatory agent
   b. Increase metabolic rate and oxygen consumption
   c. Stimulate growth in long bones at epiphyseal plates
   d. Promote water reabsorption from the renal tubules
2. A patient is given desmopressin acetate. The nurse knows that this drug is used to treat which condition?
   a. Gigantism
   b. Diabetes mellitus
   c. Diabetes insipidus
   d. Adrenal insufficiency
3. A patient is taking levothyroxine (Synthroid). For which adverse effect would the nurse monitor this patient?
   a. Tachycardia
   b. Drowsiness
   c. Constipation
   d. Weight gain
4. A patient has just begun taking calcitriol (Rocaltrol). Which is a nursing implication of this drug?
   a. Monitor the patient's weight.
   b. Monitor serum calcium levels.
   c. Teach side effects of alopecia and petechiae.
   d. Instruct the patient to avoid persons with respiratory infections.
5. A patient is given corticotropin (Acthar). The nurse knows to monitor the patient for which condition?
   a. Weight gain
   b. Hyperkalemia
   c. Hypoglycemia
   d. Dehydration
6. A nurse is administering prednisone (Deltasone) to a newly admitted patient who is taking multiple other drugs. The nurse should consider which drug interactions with prednisone? (Select all that apply.)
   a. Cardiac and CNS actions are increased when taken with an adrenergic agent.
   b. Potassium-wasting diuretics increase potassium loss, resulting in hypokalemia.
   c. Risk for GI bleeding and ulceration increases when taken with aspirin or other NSAIDs.
   d. Action of prednisone is decreased when taken with phenytoin (Dilantin) because phenytoin increases glucocorticoid metabolism.
   e. Risk for dysrhythmias and digitalis toxicity increases when taken with cardiac glycosides.
   f. Dosage of antidiabetic agents may need to be increased when taken concurrently with glucocorticoids.
7. The nurse is administering vasopressin (Pitressin) to a patient. The nurse realizes that nursing implications for this drug would include which implications? (Select all that apply.)
   a. Record urinary output.
   b. Observe the patient's weight, and note edema.
   c. Monitor the patient for decreased blood pressure.
   d. Closely monitor the patient's blood glucose levels.
   e. Monitor the patient's pulse for increased heart rate.
   f. Record the patient's daily calcium levels.

Answers: 1, c; 2, c; 3, a; 4, b; 5, a; 6, b, c, d, e, f; 7, a, b, c, e.

CHAPTER 52

Antidiabetics

evolve WEBSITE

- Key Points
- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Compare type 1 and type 2 diabetes mellitus.
- Describe the symptoms of diabetes mellitus.
- Differentiate symptoms of hypoglycemic reaction and hyperglycemia.
- Compare onset, peak and duration of rapid-acting, short-acting, intermediate-acting, and long-acting insulins.
- Compare the action of oral antidiabetic drugs and their side effects.
- Differentiate between the action of insulin, oral antidiabetic agents, and glucagon.
- Apply the nursing process to the patient taking insulin and oral antidiabetic agents.

type 1 diabetes mellitus, p. 759
type 2 diabetes mellitus, p. 759

Antidiabetic drugs are used primarily to control diabetes mellitus, a chronic disease that affects carbohydrate metabolism. There are two groups of antidiabetic agents: (1) insulin and (2) oral hypoglycemic (antidiabetic) drugs. **Insulin,** a protein secreted from the beta cells of the pancreas, is necessary for carbohydrate metabolism and plays an important role in protein and fat metabolism. The beta cells make up 75% of the pancreas, and the alpha cells that secrete glucagon, a hyperglycemic substance, occupy approximately 20% of the pancreas. **Oral hypoglycemic drugs,** also known as **oral antidiabetic drugs** (to avoid confusion with the term *hypoglycemic reaction*), are synthetic preparations that stimulate insulin release or otherwise alter the metabolic response to hyperglycemia.

TABLE 52-1 **TYPES AND OCCURRENCES OF DIABETES MELLITUS**

TYPES OF DIABETES MELLITUS	PERCENTAGE OF OCCURRENCES
Type 1	10%-12%
Type 2	85%-90%
Secondary diabetes (medications, hormonal changes)	2%-3%
GDM	1% (2%-5% of all pregnancies)

GDM, Gestational diabetes mellitus;

DIABETES MELLITUS

Diabetes mellitus, a chronic disease resulting from deficient glucose metabolism, is caused by insufficient insulin secretion from the beta cells. This results in high blood glucose *(hyperglycemia).* Diabetes mellitus is characterized by the three *p*'s: **polyuria** (increased urine output), **polydipsia** (increased thirst), and **polyphagia** (increased hunger). Diabetes *mellitus* is a disorder of the pancreas, whereas diabetes *insipidus* is a disorder of the posterior pituitary gland, discussed in detail in Chapter 51.

The four types of diabetes are presented in Table 52-1. Viral infections, environmental conditions, and genetic factors contribute to the onset of **type 1 diabetes mellitus. Type 2 diabetes mellitus** is the most common type of diabetes. Some sources suggest that heredity and obesity are the major factors that cause type 2 diabetes. With type 2 diabetes, there is some beta-cell function with varying amounts of insulin secretion. Hyperglycemia may be controlled for some type 2 diabetes patients with oral antidiabetic *(hypoglycemic)* drugs and a diet prescribed by the American Diabetic Association; however, about one third of patients with type 2 diabetes need insulin. Patients with type 2 diabetes who use one or two oral antidiabetic drugs may become insulin-dependent years later.

Certain drugs increase blood glucose and can cause hyperglycemia in prediabetic persons. These include glucocorticoids (cortisone, prednisone), thiazide diuretics (hydrochlorothiazide [HydroDIURIL]), and epinephrine. Usually the blood glucose level returns to normal after the drug is discontinued.

During the second and third trimesters of pregnancy, the levels of the hormones progesterone, cortisol, and human placental lactogen (hPL) increase. These increased hormone levels can inhibit insulin usage. This is a contributing factor for the occurrence of gestational diabetes mellitus (GDM) during pregnancy. Glucose is then mobilized from the tissue and lipid storage sites. After pregnancy, the blood glucose level may decrease; however, some patients may develop diabetes mellitus, whereas others may develop type 2 diabetes in later years.

Insulin

Insulin is released from the beta cells of the islets of Langerhans in response to an increase in blood glucose. Oral glucose load is more effective in raising the serum insulin level than an intravenous (IV) glucose load. Insulin promotes the uptake of glucose, amino acids, and fatty acids and converts them to substances that are stored in body cells. Glucose is converted to glycogen for future glucose needs in the liver and muscle, thereby lowering the blood glucose level. The normal range for blood glucose is 60 to 100 mg/dL and 70 to 110 mg/dL for serum (or plasma) glucose. When the blood glucose level is greater than 180 mg/dL, *glycosuria* (glucose in the urine) can occur. Increased blood glucose acts as an osmotic diuretic, causing polyuria. When blood glucose remains elevated (>200 mg/dL), diabetes mellitus occurs.

In 2009, the American Diabetes Association (ADA) revised its recommendations to include hemoglobin A_{1c} (HbA_{1c}) for the diagnosis of diabetes. Previously, this test had been used to monitor treatment. HbA_{1c} is a derivative of the interaction of glucose with hemoglobin in red blood cells (RBCs). Because RBCs have a life span of approximately 120 days, the HbA_{1c} level reflects the average glucose level for up to 3 months. In monitoring treatment, the goal is to keep the diabetic patient's HbA_{1c} below 7%. For diagnostic purposes, an HbA_{1c} level of ≤5% indicates that the patient does not have diabetes, 5.7% to 6.4% indicates prediabetes, and ≥6.5% indicates a diagnosis of diabetes mellitus.

Beta Cell Secretion of Insulin

The beta cells in the pancreas secrete approximately 0.2 to 0.5 units/kg/day. A patient weighing 70 kg (154 pounds) secretes 14 to 35 units of insulin per day. More insulin secretion may occur if the person consumes a greater caloric intake. A patient with diabetes mellitus may require 0.2 to 1 units/kg/day. The higher range may be because of obesity, stress, or tissue insulin resistance.

Commercially Prepared Insulin

Insulins are all currently manufactured by using deoxyribonucleic acid (DNA) technology. Human insulin (Humulin) was introduced in 1983 and duplicates insulin produced by the pancreas of the human body. Examples of human insulin include Humulin R and Novolin N. The use of Humulin insulin has a low incidence of allergic effects and insulin resistance. Human insulin analogues are modifications of human insulin with alterations in onset and duration of action. Insulin lispro (Humalog) and insulin aspart (Novolog) are examples of human insulin analogues.

Insulins are usually administered subcutaneously (subQ). Abdominal injections of insulin are absorbed faster than other body sites and found to be more consistent. Newly diagnosed patients with insulin-dependent diabetes are usually prescribed human insulin. In addition, patients in whom hyperglycemia develops during pregnancy or who already have diabetes and become pregnant are usually prescribed human insulin.

The concentration of insulin is 100 units/mL or 500 units/mL (U100/mL or U500/mL, respectively), and the insulin is packaged in a 10-mL vial. Insulin 500 units is only available in short-acting regular insulin (Humulin R and Novolin R). Insulin 500 units is seldom used except in emergencies and for patients with serious insulin resistance (>200 units/day). Insulin 40 units is no longer used in the United States, although it is still used in other countries. Insulin syringes are typically marked in units of 100 units per 1 mL or 50 units per 0.5 mL for insulin U100. Insulin syringes must be used for accurate dosing. To prevent dosage errors, the nurse must be certain that there is a match of the insulin concentration with the calibration of units on the insulin syringe. Before use, the patient or nurse must roll, not shake, cloudy insulin bottles to ensure that the insulin and its ingredients are well mixed. Shaking a bottle of insulin can cause bubbles and an inaccurate dose. Insulin requirements vary; usually less insulin is needed with increased exercise, and more insulin is needed with infections and high fever.

Administration of Insulin

Insulin is a protein and cannot be administered orally because gastrointestinal (GI) secretions destroy the insulin structure. It is administered subQ, at a 45- to 90-degree angle. The 90-degree angle is made by raising the skin and fatty tissue; the insulin is injected into the pocket between the fat and the muscle. In a thin person with little fatty tissue, the 45- to 60-degree angle is used. Regular insulin is the *only* type that can be administered IV.

The site and depth of insulin injection affect absorption. Insulin absorption is greater when given in the abdominal areas than when given in the thigh and buttock areas. Heat and massage could increase subQ absorption. Cooling the subQ area can decrease absorption.

Insulin is usually given in the morning before breakfast. It can be given several times a day. Insulin injection sites should be rotated to prevent **lipodystrophy** (tissue atrophy or hypertrophy), which can interfere with insulin absorption. Lipoatrophy (tissue atrophy) is a depression under the skin surface that primarily occurs in women and children. Lipohypertrophy (tissue hypertrophy) is a raised lump or knot on the skin surface that is more common in men. It is frequently caused by repeated injections into the same subQ site. The patient needs to develop a "site rotation pattern" to avoid lipodystrophy and to promote insulin absorption. There are various insulin rotation programs, such as an 8-day rotation schedule (insulin is given at a different site each day). The ADA suggests that insulin be injected daily at a chosen site for 1 week. Injections should be 1.5 inches apart (a knuckle length) at a site area each day. When a patient requires two insulin injections a day (morning and evening), one site should be chosen on the right side (morning) and one site chosen on the left side (evening). Figure 52-1 illustrates the sites for insulin injections. A record of injection area sites and dates administered should be kept.

Illness and stress increase the need for insulin. Insulin doses should *not* be withheld during illness, including infections and stress. Hyperglycemia and ketoacidosis may result from insufficient insulin.

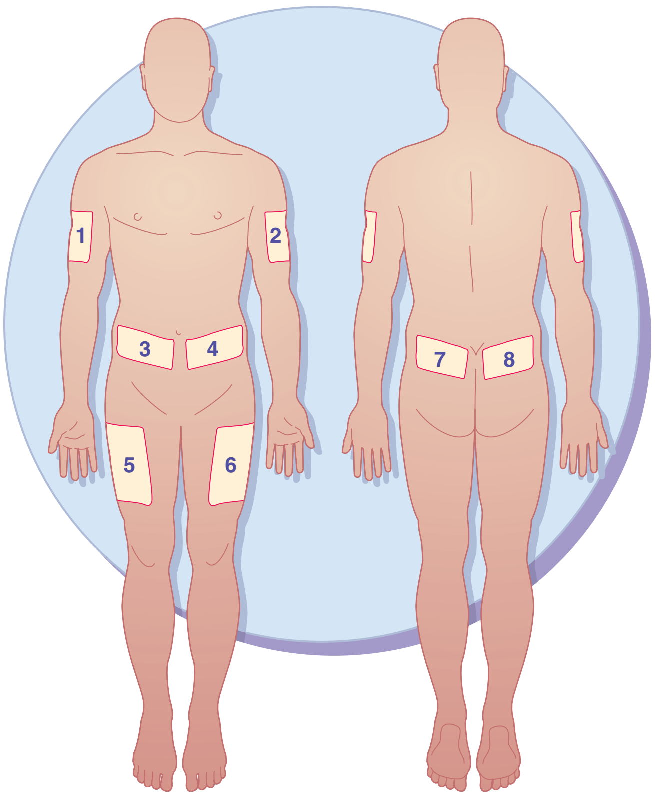

FIGURE 52–1 Sites for insulin injection.

Types of Insulin

There are several standard types of insulin: rapid acting, short acting, intermediate acting, long acting, and combinations. Rapid- and short-acting insulins are in a clear solution without any added substance to prolong insulin action. Intermediate-acting insulins are cloudy and may contain protamine, a protein that prolongs the action of insulin, or zinc, which also slows the onset of action and prolongs the duration of activity.

Rapid-acting insulins include insulin lispro (human analog) (Humalog) and human insulin aspart (rDNA origin) (NovoLog). Insulin lispro is formed by reversing two amino acids in human regular insulin (Humulin). Insulin aspart (rDNA origin) is another human insulin analogue in which a single amino acid (proline) has been substituted with aspartic acid to help prevent the molecules from clumping together to allow quicker entry into blood circulation. Insulin lispro and insulin aspart act faster than regular insulin, so they must not be administered more than 5 minutes before mealtime (food should be present before administering these insulins). Patients who are insulin-dependent and take rapid-acting insulin usually require intermediate-acting insulin as well.

Short-acting insulin has an onset of action in 30 minutes to 1 hour. The peak action occurs in 2.5 to 5 hours, and the duration of action is 6 to 8 hours. Regular (unmodified, crystalline) insulin is short-acting insulin that can be administered IV and subQ. Regular insulin is generally given 30 minutes before meals.

Intermediate-acting insulins include neutral-protamine-Hagedorn (NPH), Lente, and Humulin N. Isophane insulins like NPH and Humulin N contain protamine, a protein that prolongs the action of insulin. Humulin L insulin contains zinc, which also prolongs the insulin action time. The onset of intermediate-acting insulin is 1 to 2 hours, peak action occurs in 6 to 12 hours, and the duration of action is 18 to 24 hours.

Insulin glargine (Lantus) is long-acting insulin with an onset of 1 hour. It is evenly distributed over a 24-hour duration of action; thus it is administered once a day, usually at bedtime. Incidence of nocturnal hypoglycemia is not as common as with other insulins because of its continuous sustained release. Insulin detmir (Levemir) is another long-acting insulin that peaks in 6 to 8 hours and lasts for 12 to 24 hours. These two insulins are analogues of human insulin. Approved by the FDA in 2000, Glargine was the first long-acting recombinant DNA (rDNA origin) human insulin for patients with types 1 and 2 diabetes. Glargine and detmir are available in a prefilled 3-mL cartridge for the "OptiPen One" insulin pen device. Some patients complain of more pain at the injection site with the administration of glargine than with NPH insulin.

Combination insulins are commercially premixed. These include Humulin 70/30, Novolin 70/30, Humulin 50/50, and Humalog Mix 75/25. These combinations are widely used. The Humulin 70/30 vials or prefilled disposable pens contain 70% of human insulin isophane (intermediate-acting insulin, NPH) and 30% regular (fast-acting) insulin. The exterior of an insulin pen resembles a fountain pen. The Humulin 50/50 vial or pen contains 50% isophane (NPH) insulin and 50% regular insulin. The Humalog 75/25 mix is available in vials or prefilled disposable pens and contains 75% lispro protamine insulin and 25% lispro "rapid" insulin. Humalog 75/25 helps prevent hypoglycemia, which could occur with the 70/30 or 50/50 combination insulins, and helps control hyperglycemia more effectively. The 75/25 pen contains 300 units of insulin and does not require refrigeration after first use. It can be stored at room temperature for up to 10 days. With these combinations of insulin, the patient does not have to mix regular and NPH insulins as long as one of these combinations is effective. However, some patients need less than 25% or 30% regular insulin and more intermediate-acting insulin. These patients needs to mix the two insulins in the prescribed proportions.

Regular insulin can be mixed with protamine or zinc insulin in the same syringe. However, mixing insulin can alter the absorption rate.

Insulin Resistance

Antibodies develop over time in persons taking animal insulin. This can slow the onset of insulin action and extend its duration of action. Antibody development can cause insulin resistance and insulin allergy. Obesity can also be a causative factor for insulin resistance. Skin tests with different insulin preparations may be performed to determine whether there is an allergic effect. Human and regular insulins produce fewer allergens.

Storage of Insulin

Unopened insulin vials are refrigerated until needed. Once an insulin vial has been opened, it may be kept (1) at room temperature for 1 month or (2) in the refrigerator for 3 months. Insulin is less irritating to the tissues when injected at room temperature. Insulin vials should not be put in the freezer. In addition, insulin vials should not be placed in direct sunlight or in a high-temperature area. Prefilled syringes should be stored in the refrigerator and should be used within 1 to 2 weeks. Opened insulin vials lose their strength after approximately 3 months.

Prototype Drug Chart 52-1 lists the pharmacologic data for the different types of insulin.

Pharmacokinetics All insulins can be administered subQ, but only regular insulin can be given IV. The half-life varies. Insulin is metabolized by the liver and muscle and is excreted in the urine.

Pharmacodynamics Insulin lowers blood sugar by promoting the use of glucose by the body's cells. Insulin is also active in the storage of glucose as glycogen in muscles. The onset of action of rapid-acting insulin given subQ is 5 to 15 minutes. The onset of action of regular insulin is 30 minutes to 1 hour given subQ and 10 to 30 minutes given IV. The onset of action of intermediate-acting insulin is 1 to 2 hours. The peak action of insulins is important because of the possibility of hypoglycemic reaction (insulin shock) occurring during that time. The peak action for rapid-acting insulin is 30 minutes to 3 hours. The peak time for regular insulin is 2.5 to 5 hours; for intermediate-acting insulin, it is 6 to 12 hours. The nurse needs to assess for signs and symptoms of hypoglycemic reaction, such as nervousness, tremors, confusion, sweating, and increased pulse rate. Orange juice, sugar-sweetened beverages, or hard candy should be kept available and given if a reaction occurs. If patient is unable to ingest fast acting carbohydrates, glucagon may be given. Glucagon promotes the breakdown of glycogen in the liver, raising blood glucose within 10 minutes.

Regular insulin can be given several times a day, especially during the regulation of insulin dosage. Intermediate- and long-acting insulins are usually administered once a day. Regular insulin can be mixed with intermediate-acting insulin (Humulin N), especially if rapid onset of action is needed. When switching from one type of insulin to another, the patient may require a dose adjustment because human insulin has a shorter duration of action.

Sliding-Scale Insulin Coverage

Insulin may be administered in adjusted doses that depend on individual blood glucose test results. When the diabetic patient has extreme variances in insulin requirements (e.g., stress from hospitalization, surgery, illness, or infection), adjusted dosing or sliding-scale insulin coverage provides a more constant blood glucose level. Blood glucose testing is performed several times a day at specified intervals (usually before meals). A preset scale usually involves directions for the administration of rapid- or short-acting insulin.

Drug Interactions. Drugs such as thiazide diuretics, glucocorticoids (cortisone preparations), thyroid agents, and estrogen increase the blood sugar; therefore the insulin dosage may need adjustment. Drugs that decrease insulin needs are tricyclic antidepressants, monoamine oxidase inhibitors (MAOIs), aspirin products, and oral anticoagulants.

PROTOTYPE DRUG CHART 52-1

Insulins

Drug Class Antidiabetic: insulin Humalog (Lispro)—rapid-acting Regular Humulin R—short-acting Humulin N—intermediate-acting Glargine (Lantus)—long-acting Pregnancy Category: B	**Dosage** Must be individualized. Varies according to patient's blood sugar and health status
Contraindications Hypersensitivity, hypoglycemia Caution: Hypokalemia, fever, surgery or trauma, nausea or vomiting	**Drug-Lab-Food Interactions** Drug: Increased hypoglycemic effect with aspirin, oral anticoagulant, alcohol, oral hypoglycemics, beta blockers, tricyclic antidepressants, MAOIs, tetracycline; decreased hypoglycemic effect with thiazides, glucocorticoids, oral contraceptives, thyroid drugs, smoking
Pharmacokinetics Absorption: Lispro and Humulin R rapidly absorbed from subQ injection site. Humulin N absorbed at a slower rate. Glargine absorbed at a slow, evenly distributed rate. Distribution: PB: UK Metabolism: t½: varies with type of insulin Excretion: Mostly in urine	**Pharmacodynamics** Lispro (Humalog): subQ: Onset: 5-15 min Peak: 30-60 min Duration: 3-4 h Regular Humulin R: subQ: Onset: 30-60 min Peak: 2.5-5 h Duration: 4-8 h Humulin N: subQ: Onset: 1-2 h Peak: 4-12 h Duration: 18-24 h Glargine (Lantus): subQ: Onset: 1 h Peak: None Duration: 24 h
Therapeutic Effects/Uses To control diabetes mellitus; to lower blood sugar Mode of Action: Promotes use of glucose by body cells.	
Side Effects Confusion, agitation, tremors, headache, flushing, hunger, weakness, lethargy, fatigue, urticaria, redness, irritation or swelling at injection site	**Adverse Reactions** Tachycardia, palpitations, hypoglycemic reaction, rebound hyperglycemia (Somogyi effect), lipodystrophy Life-threatening: Shock, anaphylaxis

h, Hour; *MAOI,* monoamine oxidase inhibitor; *min,* minute; *PB,* protein-binding; *subQ,* subcutaneous; *t ½,* half-life; *UK,* unknown.

Table 52-2 lists the rapid-acting, short-acting, intermediate-acting, long-acting, and combination insulins with their dosages, uses, and considerations.

Side Effects and Adverse Reactions: Hypoglycemic Reactions and Ketoacidosis. When more insulin is administered than needed for glucose metabolism, a **hypoglycemic reaction,** or **insulin shock,** occurs. The person may exhibit nervousness, trembling, and lack of coordination; have cold and clammy skin; and complain of a headache. Some patients become combative and incoherent. Giving sugar orally or IV increases the use of insulin, and the symptoms disappear immediately.

In response to an excessive dose of insulin, diabetic patients may develop the Somogyi effect. This hypoglycemic condition usually occurs in the predawn hours of 2:00 AM to 4:00 AM. A rapid decrease in blood glucose during the nighttime hours stimulates a release of hormones (e.g., cortisol, glucagon, epinephrine) to increase blood glucose by lipolysis, gluconeogenesis, and glycogenolysis, thus creating the Somogyi effect. Management of the Somogyi effect involves monitoring blood glucose between 2:00 AM and 4:00 AM and reducing the bedtime insulin dosage.

Hyperglycemia on awakening is known as the *dawn phenomenon.* The patient usually awakens with a headache and

				ONSET	PEAK	DURATION
Rapid-Acting Insulins						
insulin lispro (Humalog) insulin aspart [rDNA origin] (NovoLog) insulin glulisine (Apidra)	A: 0.5-1 unit/kg/d; dose individualized	Humalog: B NovoLog, Apidra: C	26-81 min	5-15 min	Humalog, Apidra: 30-90 min NovoLog: 1-3 h	Humalog: 2-5 h NovoLog: 3-5 h Apidra: 1-2.5 h
Short-Acting Insulins						
insulin regular (Humulin R, Novolin R, regular insulin)	A/C: subQ/IV: 100 units/mL; dose individualized	B	10 min-1 h	30 min	2.5-5 h	6-8 h
Intermediate-Acting Insulins						
insulin isophane NPH (Humulin N, Novolin N)	See Prototype Drug Chart 52-1.	B	13 h	1-2 h	6-12 h	18-24 h
Long-Acting Insulins						
insulin glargine (Lantus)	Dose individualized	C	UK	1 h	None	24 h
insulin detemir (Levemir)	Dose individualized	B	5-7 h	3-4 h	6-8 h	24 h
Combination Insulins*						
Humulin 70/30 (isophane NPH 70%, regular 30%)	Dose individualized	B	13 h	30 min	4-8 h	22-24 h
insulin isophane NPH 50/50 (Humulin NPH 50%, regular 50%)	Dose individualized	B	13 h	0.5 h	4-8 h	24 h
Humalog 75/25 (lispro protamine 75%, lispro 25%)	Dose individualized	B	<13 h	5-15 min	0.5-6 h	20-24 h

*Protamine suspensions are added to regular insulin.

A, Adult; *C,* child; *h,* hour; *IV,* intravenous; *min,* minute; *NPH,* neutral-protamine-Hagedorn; *subQ,* subcutaneous; *UK,* unknown; <, less than.

reports night sweats and nightmares. Management of the dawn phenomenon involves increasing the bedtime dose of insulin.

With an inadequate amount of insulin, sugar cannot be metabolized, and fat catabolism occurs. The use of fatty acids (ketones) for energy causes **ketoacidosis** (diabetic acidosis or diabetic coma). Table 52-3 lists the signs and symptoms of hypoglycemic reaction and ketoacidosis.

Insulin Pen Injectors

An insulin pen resembles a fountain pen. The pen contains a disposable needle and a disposable insulin-filled cartridge. Insulin pens come in two types: prefilled and reusable. These insulin pens are considered to deliver a more accurate dose than the traditional 100-unit syringe and vial.

To operate the insulin pen, the insulin dose is obtained by turning the dial to the number of insulin units needed. The capacity of these prefilled and reusable-insulin pens is 150 to 300 units, or 1.5 to 3 mL. The 1.5-mL replaceable cartridges for insulin pens are being phased out. Insulin pens available on the market include Novolog FlexPen (Novo Nordisk), Humalog KwikPen (Lilly), Apidra SoloSTAR (Sanofi-Aventis), Lantus SoloSTAR (Sanofi), and Levemir FlexPen (Novo Nordisk). Insulin pens tend to be more expensive than other delivery systems, but their advantages may outweigh the extra cost.

TABLE 52-3 HYPOGLYCEMIC REACTION AND DIABETIC KETOACIDOSIS

REACTION	SIGNS AND SYMPTOMS
Hypoglycemic reaction (insulin shock)	Headache, lightheadedness Nervousness, apprehension Tremor Excess perspiration; cold, clammy skin Tachycardia Slurred speech Memory lapse, confusion, seizures Blood sugar level <60 mg/dL
Diabetic ketoacidosis (hyperglycemic reaction)	Extreme thirst Polyuria Fruity breath odor Kussmaul breathing (deep, rapid, labored, distressed, dyspneac) Rapid, thready pulse Dry mucous membranes, poor skin turgor Blood sugar level 250 mg/dL

>, Greater than; <, less than.

The use of insulin pens increases the patient's compliance with the insulin regimen. The convenience of the pen is most appealing. The patient may choose to use the insulin pen for its portability (e.g., at work, while traveling). The traditional method for administering insulin may be used at other times. The cost of insulin in vials is somewhat less than the prefilled pens, but most patients state that less injection pain is associated with insulin pens than with the traditional insulin syringe.

Insulin Pumps

Insulin pumps are an alternative to daily insulin injections used in association with blood glucose monitoring and carbohydrate counting. These computerized devices have an insulin reservoir and programming capacity to deliver continuous rapid-acting insulin in varying amounts at different times throughout a 24-hour period. These pumps are smaller than most mobile phones. Types of insulin pumps include implantable and portable. The implantable insulin pump is surgically implanted in the abdomen. It delivers both basal infusion (continuous release of a small amount of insulin) and bolus (additional) doses with meals. It is administered intraperitoneally. With the use of implantable insulin pumps, fewer hypoglycemic reactions occur and blood glucose levels are controlled. Long-term effectiveness of the pump is currently under study.

Portable or external insulin pumps, also called *continuous subQ insulin infusion* (CSII), may have a tube (or infusion set) placed under the skin. The needle is inserted into the abdomen, upper thigh, or upper arm. This type of pump is worn outside the body and placed in a pocket or bra. The external tubeless pump lies directly on the skin and injects insulin through the skin without tubes. The external insulin pump keeps blood glucose levels as close to normal as possible. This insulin pump is a battery-operated device that uses rapid-acting insulin, which is stored in a reservoir syringe placed inside the device. It delivers both basal insulin infusion and bolus doses with meals. Infusions are programmed by the patient. About three basal rates are programmed per day; however, the patient can adjust the rate according to changes in activity. The insulin can be delivered by bolus (the patient pushes a button to deliver a bolus dose at meals). Only rapid-acting insulin is used. Modified insulins (NPH) are not used because of unpredictable control of blood sugars. The pump delivers exactly as much insulin as the patient programs.

The ongoing insulin delivery therapy helps decrease the risk of severe hypoglycemic reaction and maintains tight glucose (glycemic) control. Glucose levels should be monitored at least four times daily with an insulin pump. The patient must count carbohydrates and bolus prior to meals.

Most insulin pumps have a memory of the last 24 boluses (time and day). An alarm sounds so the patient can take appropriate action when insulin is not delivered or when there is an oncoming low or high. Newer pumps have an automatic shutoff for 1 to 2 hours during periods of low blood glucose. This feature is designed for the patient that may not hear the alarm and for whom blood glucose is allowed to elevate. The pump can be disconnected from the insertion site for bathing, swimming, and other activities; however, it is recommended that it not be discontinued for longer than 1 to 2 hours.

Success of insulin pump therapy depends on the individual's knowledge and compliance related to insulin use and the diabetic state. The person with type 1 diabetes mellitus may benefit most from the use of insulin pump therapy. This insulin delivery method is considered more effective than the use of multiple injections of regular and modified types of insulins and lessens the long-term diabetic complications. Studies have shown that myocardial infarction, renal disease, nerve damage, eye damage, and death have all been greatly reduced by tight blood glucose control. Also, HbA_{1c} levels, neuropathy pain, and sexual performance have improved with the use of insulin pump control.

Insulin Jet Injectors

Insulin jet injectors shoot insulin, without a needle, directly through the skin into the fatty tissue. Because the insulin is delivered under high pressure, stinging, pain, burning, and bruising may occur. This method of insulin insertion is not indicated for children or older adults. This type of device is also expensive, costing approximately 2 to 10 times as much as the subQ dose.

Nursing Process
Patient-Centered Collaborative Care

Antidiabetics: Insulin

Assessment

- Identify the drugs patient currently takes. Certain drugs such as alcohol, aspirin, oral anticoagulants, oral antidiabetics, beta-blockers, tricyclic antidepressants, monoamine oxidase inhibitors (MAOIs), and tetracycline increase the hypoglycemic effect when taken with insulin. Note that thiazides, glucocorticoids, oral contraceptives, thyroid drugs, and smoking can increase blood sugar.
- Assess the type of insulin and dosage. Note whether it is given once or multiple times a day.
- Note BP, heart rate, and blood glucose levels. Tachycardia and heart palpitations may occur with hypoglycemia. Hypotension may occur with hyperglycemia. Report abnormal findings.
- Determine patient's knowledge of diabetes mellitus and use of insulins.
- Check for signs and symptoms of hypoglycemic reaction (insulin shock), hyperglycemia, or ketoacidosis.

Nursing Diagnoses

- Risk for impaired skin integrity related to failure to rotate insulin injection sites

- Imbalanced nutrition, more than body requirements, related to excessive intake associated with metabolic need
- Risk for injury related to confusion from hypoglycemic reaction
- Deficient knowledge related to inexperience with insulin therapy

Planning

- Patient's blood glucose will be within normal values (70 to 110 mg/dL).
- Patient will self-administer insulin correctly.

Nursing Interventions

- Monitor vital signs. Tachycardia can occur during insulin reaction.
- Determine blood glucose levels, and report changes. The reference value is 60 to 100 mg/dL for blood glucose and 70 to 110 mg/dL for serum glucose.
- Monitor the patient's HbA$_{1c}$ to provide feedback of diabetic control.
- Prepare a teaching plan based on patient's knowledge of health problem, diet, and drug therapy.

Patient Teaching

General

- Teach patient to recognize and immediately report symptoms of hypoglycemic (insulin) reaction, such as headache, nervousness, sweating, tremors, rapid pulse, and hyperglycemic reaction (diabetic acidosis), such as thirst, increased urine output, and sweet, fruity breath odor.
- Advise patient that hypoglycemic reactions are more likely to occur during peak action time. Most diabetic patients know whether they are having a hypoglycemic reaction, but some have higher tolerance to low blood glucose and can have a severe reaction without realizing it.
- Explain that orange juice, sugar-containing drinks, and hard candy may be used when a hypoglycemic reaction begins.
- Teach family members to administer glucagon by injection if patient has a hypoglycemic reaction and cannot drink sugar-containing fluid.
- Inform patient that certain herbs may interact with insulin and oral antidiabetic drugs. A hypoglycemic or hyperglycemic effect might occur (Herbal Alert 52-1).
- Teach patient about necessity for compliance with prescribed insulin therapy and diet. HbA$_{1c}$ provides most accurate picture of optimal diabetic control.
- Advise patient to carry a MedicAlert card, tag, or bracelet indicating the health problem and insulin dosage.

Self-Administration

- Instruct patient on how to check blood glucose with a glucometer (Sure Touch, One Step, Accu-Chek).
- Teach patient about care of insulin container and syringes. Inform patient taking NPH insulin with regular insulin that regular insulin is drawn up before NPH insulin.

Diet

- Advise patient taking insulin to eat prescribed diet on a consistent schedule. Diet information may be obtained from ADA or a nutritionist.

Cultural Considerations

- Provide additional instructions about insulin action, administration, reactions, and possible complications in language patient speaks and reads most easily.
- Determine if follow-up by community health nurse is needed to assist with patient's compliance with insulin use, diet, and exercise regimen.

Evaluation

- Evaluate effectiveness of insulin therapy by noting if blood sugar level is within accepted range.
- Establish patient's self-care ability.
- Determine patient's knowledge of signs and symptoms of hypoglycemic or hyperglycemic reaction.

HERBAL ALERT 52-1

Antidiabetic Agents

- Chromium may decrease insulin requirements.
- Black cohosh may potentiate hypoglycemic effects of insulin and oral antidiabetic drugs.
- Garlic, bitter melon, aloe, and gymnema can increase insulin levels and therefore may cause hypoglycemia when used with insulin or oral antidiabetic drugs. They can have a direct hypoglycemic effect.
- Ginseng can lower blood glucose levels. When taken with insulin or an oral antidiabetic (hypoglycemic) drug, hypoglycemic effects or reaction may occur.
- Bilberry may increase hypoglycemia when taken with insulin or oral antidiabetics.
- Rosemary and stinging nettle decrease the therapeutic effect of insulin and oral antidiabetic drugs (have a hyperglycemic effect).

Oral Antidiabetic Drugs (Oral Hypoglycemic Drugs)

First- and Second-Generation Sulfonylureas

Oral antidiabetic drugs, also called *oral hypoglycemics,* should be used by those with type 2 diabetes; persons with type 1 diabetes should not use them. Patients with type 2 diabetes have some degree of insulin secretion by the pancreas. The sulfonylureas, a group of antidiabetics chemically related to sulfonamides but lacking antibacterial activity, stimulate pancreatic beta cells to secrete more insulin. This increases the insulin cell receptors, increasing the ability of the cells to bind insulin for glucose metabolism.

The sulfonylureas are classified as first- and second-generation. First-generation sulfonylureas are divided into short-acting, intermediate-acting, and long-acting antidiabetics. Tolbutamide (Orinase) is a first-generation short-acting sulfonylurea. Tolazamide (Tolinase) is a first-generation intermediate-acting sulfonylurea. Chlorpropamide (Diabinese) is a first-generation long-acting sulfonylurea.

Second-generation sulfonylureas increase the tissue response to insulin and decrease glucose production by the liver. They have greater hypoglycemic potency than the first-generation sulfonylureas. Effective doses for the second-generation drugs are lower than for the first-generation drugs. They have a longer duration of action and cause fewer side effects. The second-generation drugs have less displacement potential from protein-binding sites by other highly protein-bound drugs, such as salicylates and warfarin (Coumadin), than first-generation drugs. Second-generation sulfonylureas should not be used when liver or kidney dysfunction is present. A hypoglycemic reaction is more likely to occur in older adults.

Second-generation sulfonylureas include glimepiride (Amaryl) and glipizide (Glucotrol, Glucotrol XL), which directly stimulate the beta cells to secrete insulin, thus decreasing the blood glucose level. Glimepiride improves postprandial glucose levels. It may be used in combination with insulin in persons with type 2 diabetes. Side effects include GI disturbances such as nausea, vomiting, diarrhea, and abdominal pain.

Table 52-4 lists the sulfonylureas and their dosages, uses, and considerations. Prototype Drug Chart 52-2 lists the pharmacologic data for the second-generation sulfonylurea glipizide.

Pharmacokinetics Glipizide is well absorbed from the GI tract and highly protein-bound. Glipizide is metabolized by the liver. The primary metabolites are inactive and excreted mainly in urine.

Pharmacodynamics Glipizide is the most common sulfonylurea drug prescribed for type 2 diabetes mellitus. It lowers blood sugar by stimulating pancreatic beta cells to secrete insulin. The onset of action usually occurs within 15 to 30 minutes, and the peak action time is between 1 and 2 hours. Glipizide is normally given once a day in the morning because of its long duration of action of 24 hours.

TABLE 52-4 ANTIDIABETICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
First-Generation Sulfonylureas: Short Acting		
tolbutamide (Orinase)	A: PO: 250-3,000 mg/d in 1-2 divided doses	For managing type 2 diabetes mellitus. Chemically related to sulfonamides, but no antiinfective effect. Hypoglycemic reaction may occur if overdosed. Pregnancy category: C; PB: 98%; t½: 4-7 h
First-Generation Sulfonylureas: Intermediate Acting		
tolazamide (Tolinase)	A: PO: 100-250 mg 1-2 times/d *max:* 1 g/d	Diet and exercise should be part of diabetic therapy. Duration of action is 10-20 hours. Pregnancy category: C; PB: 90%; t½: 7 h
First-Generation Sulfonylureas: Long Acting		
chlorpropamide (Diabinese)	A: PO: 100-250 mg/d; *max:* 750 mg/d	For managing type 2 diabetes. May be given to selected type 1 patients for reducing insulin doses. Diet and exercise should be a part of diabetic therapy. Duration of action is 24 h. May cause water and sodium retention. Pregnancy category: C; PB: 60%-90%; t½: 25-60 h
Second-Generation Sulfonylureas		
glipizide (Glucotrol)	See Prototype Drug Chart 52-2.	
glyburide (DiaBeta, Glynase, Micronase)	A: PO: Initially: 1.25-5 mg/d; maint: 1.25-20 mg/d; *max:* 20 mg/d	Same as chlorpropamide. Potent drug. Duration of action 10-24 h. Pregnancy category: C; PB: 99%; t½: 10 h
glimepiride (Amaryl)	A: PO: Initially: 1-2 mg a.c.; maint: 1-4 mg/d a.c.; *max:* 8 mg/d a.c.	For managing type 2 diabetes. May be used in combination with insulin. Can lower 2-hour postprandial glucose levels significantly. GI disturbances may occur. Pregnancy category: C; PB: 99%; t½: 5-9 h
Nonsulfonylureas		
Biguanides		
metformin (Glucophage)	See Prototype Drug Chart 52-3.	
Alpha-Glucosidase Inhibitors		
acarbose (Precose)	A: PO: Initially 25 mg t.i.d. with first bite of each meal; *max:* 150 mg/d if <60 kg, 300 mg/d if >60 kg	For managing hyperglycemia in type 2 diabetes mellitus. Used as monotherapy or in combination with a sulfonylurea. Pregnancy category: B; PB: UK; t½: 2 h
miglitol (Glyset)	A: PO: 25-100 mg t.i.d. a.c.	For managing type 2 diabetes. May be taken with a sulfonylurea or as monotherapy with diet and exercise. GI disturbances may occur. Pregnancy category: B; PB: <4%; t½: 2 h

TABLE 52-4 ANTIDIABETICS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Thiazolidinediones (Insulin-Enhancing Agents)		
pioglitazone HCl (Actos)	A: PO: 15-45 mg/d	For managing type 2 diabetes. Improves glycemic control and decreases insulin resistance. Inhibits gluconeogenesis and increases sensitivity to insulin in muscle and fatty tissues. For monotherapy; can be combined with sulfonylurea or insulin. Monitor liver enzymes. Contraindicated for patients with symptomatic heart disease and Class III and IV CHF. Pregnancy category: C; PB: 99%; t½: 16-24 h
Meglitinides		
repaglinide (Prandin)	A: PO: 0.5-4 mg t.i.d./q.i.d. a.c.; *max:* 16 mg/d	For managing type 2 diabetes. May be taken alone or in combination with metformin. Similar in action to sulfonylureas but not in structure. Increases beta cell secretion of insulin. Pregnancy category: C; PB: 98%; t½: 1 h
nateglinide (Starlix)	A: PO: 60-120 mg t.i.d. a.c.; *max:* 360 mg/d	For managing type 2 diabetes. Increases release of insulin from beta cells. May be used alone or in combination with metformin. Pregnancy category: C; PB: 98%; t½: 1.5 h
DPP-4 Inhibitors		
sitagliptin phosphate (Januvia) Combination form: sitagliptin/metformin (Janumet)	A: PO: 100 mg/d	For managing type 2 diabetes. Used in combination with exercise and diet. Pregnancy category: B; PB: 38%; t½: 12 h
saxagliptin (Onglyza)	A: PO: 2.5-5 mg/d	For managing type 2 diabetes. Used in combination with exercise and diet. Pregnancy category: B; PB: UK; t½: 2.5 h
linagliptin (Tradjenta)	A: PO: 5 mg/d	For managing type 2 diabetes. Used in combination with exercise and diet. Pregnancy category: B; PB: 75%-99%; t½: 12 h
alogliptin (Nesina)	A: PO: 25 mg/d	For managing type 2 diabetes. Used in combination with exercise and diet. Pregnancy category: B; PB: 20%; t½: 21 h
Selective Sodium-Glucose Transporter 2		
canagliflozin (Invokana)	A: PO: 100 mg/d before first meal of day; *max:* 300 mg/d	For managing type 2 diabetes. Used in combination with exercise and diet. Pregnancy category: C; PB: 99%; t½: 10.6-13.1 h
Amylin Analogue		
pramlintide (Symlin)	Type 1: A: subQ: Initially 15 mcg a.c., then 30-60 mcg; *max:* 120 mcg/dose Type 2: A: subQ: Initially 60 mcg a.c., then 60-120 mcg; *max:* 120 mcg/dose	For managing types 1 and 2 diabetes as adjunct to insulin therapy. Decreases postmeal glucagon and glucose. Give subQ in abdomen and thigh immediately before each major meal. Never administer in arm as absorption is unpredictable. Pregnancy category: C; PB: 40%; t½: 48 min
Glucagon-Like Peptide-1 Agonists		
exenatide (Byetta, Bydureon)	Injectable suspension (Byetta): A: subQ: 5 mcg b.i.d within 60 min before morning and evening meal; *max:* 20 mcg/d Injectable suspension (Bydureon): A: subQ: 2 mg/week	For managing type 2 diabetes. Suppresses glucagon secretion. May be given in abdomen, arm, or thigh. Pregnancy category: C; PB: 40%; t½: 2.4 h
liraglutide (Victoza)	A: subQ: 0.6 mg/d for 1 wk, then 1.2-1.8 mg/d	For managing type 2 diabetes. Monitor patient closely; may cause thyroid C-cell tumors. Pregnancy category: C; PB: 98%; t½: 12-13 h
Fixed Combination Oral Antidiabetic Drugs		
glyburide/metformin (Glucovance)	A: PO: Initially: 1.25/250 mg (glyburide/metformin) once daily or b.i.d. a.c. Increase dose at 2-wk intervals; maint: 2.5/510 mg/d or 5/510 mg/d or b.i.d. a.c.; *max:* 20/2,000 mg/d	For managing type 2 diabetes. May be used when glucose is not controlled with either drug alone. Contraindicated for patients with renal insufficiency because of risk for lactic acidosis. Pregnancy category: B; PB: UK; t½: 6-10 h

A, Adult; *a.c.,* before meals; *b.i.d.,* twice a day; *CHF,* congestive heart failure; *d,* day; *GI,* gastrointestinal; *h,* hour; *maint,* maintenance; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week; *>,* greater than; *<,* less than.

PROTOTYPE DRUG CHART 52-2

Glipizide

Drug Class

Glipizide: sulfonylurea, second-generation

Trade Names: Glucotrol, Glucotrol XL

Pregnancy Category: C

Dosage

A: PO: Initially 2.5-5 mg/d a.c.; maint: 10-15 mg/d a.c. (dose is divided if >15 mg); *max:* 40 mg/d

A: PO: ER: 5-10 mg/d; *max:* 20 mg/d

Contraindications

Diabetic ketoacidosis

Caution: Hepatic or renal dysfunction, older adults, debilitated or malnourished patients, adrenal or pituitary insufficiency

Drug-Lab-Food Interactions

Drug: Alcohol may produce disulfiram-like reaction (flushing, headache, sweating, nausea, violent vomiting, weakness); beta blockers, systemic azole antifungals, clarithromycin, oral anticoagulants, MAOIs, atypical antipsychotics, salicylates, probenecid, sulfonamides, antacids, cimetidine, clofibrate, and phenylbutazone may potentiate hypoglycemia; oral contraceptives, thiazide diuretics, and anticonvulsants may enhance hyperglycemia.

Lab: Altered liver function tests

Food: Green tea may potentiate hypoglycemia

Pharmacokinetics

Absorption: Rapidly absorbed from GI tract

Distribution: PB: 92%-99%

Metabolism: $t_{1/2}$: 2-4 h

Excretion: Primarily in urine

Pharmacodynamics

PO: Onset: 15-30 min

Peak: 1-2 h

Duration: 12-24 h

Therapeutic Effects/Uses

To control hyperglycemia in type 2 diabetes mellitus

Mode of Action: Directly stimulates beta cells in pancreas to secrete insulin; indirectly alters sensitivity of peripheral insulin receptors, allowing increased insulin binding

Side Effects

Drowsiness, headache, confusion, visual disturbances, anxiety, hunger, anorexia, nausea, constipation, diarrhea

Adverse Reactions

Hypoglycemia, tachycardia

Life-threatening: Seizures, coma, respiratory depression

A, Adult; *a.c.,* before meals; *d,* day; *GI,* gastrointestinal; *h,* hour; *MAOIs,* monoamine oxidase inhibitors; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *ER,* extended-release; $t_{1/2}$, half-life; *>,* greater than.

Side Effects, Adverse Reactions, and Contraindications. The side effects of most oral antidiabetic drugs are similar to those of insulin. Taking antidiabetic drugs without adequate food can lead to an insulin reaction with signs and symptoms such as nervousness, tremors, and confusion. Adverse reactions include hematologic disorders, such as aplastic anemia, leukopenia, and thrombocytopenia. Weight gain, seizures, and coma may also occur. Sulfonylureas are contraindicated in type 1 diabetes (no functioning beta cells), diabetic ketoacidosis, pregnancy, and lactation and during stress, surgery, or severe infection.

The major side effect of sulfonylureas is hypoglycemia. Acarbose does not cause hypoglycemia unless it is taken with a sulfonylurea or insulin. It can cause increased flatulence (gas), diarrhea, and abdominal distention.

Drug Interactions. Aspirin, oral anticoagulants, MAOIs, sulfonamides, cimetidine, and some NSAIDs can increase the action of sulfonylureas, especially first-generation ones, by binding to plasma proteins and displacing sulfonylureas. Because this causes increased free sulfonylurea, insulin reaction can result. The action of sulfonylureas is decreased by concurrent administration of thiazide diuretics, isoniazid, phenytoin, and corticosteroids. Patients should be alerted not to drink alcohol while taking sulfonylureas, because alcohol increases the half-life, and a hypoglycemic reaction can result.

Nonsulfonylureas

Expanding knowledge of glucose metabolism has revealed new mechanisms for the management of type 2 diabetes. The drugs metformin and acarbose use different methods to control serum glucose levels following a meal. Unlike the sulfonylureas, which enhance insulin release and receptor interaction, these drugs affect the hepatic and GI production of glucose.

Biguanides: Metformin (Glucophage)

Metformin is a biguanide compound that acts by decreasing hepatic production of glucose from stored glycogen. This diminishes the increase in serum glucose following a meal and blunts the degree of postprandial hyperglycemia. Metformin also decreases the absorption of glucose from the small intestine, and there is evidence that it increases insulin receptor sensitivity as well as peripheral glucose uptake at the cellular level. Unlike sulfonylureas, metformin does not produce hypoglycemia or hyperglycemia. It can cause GI disturbances.

Metformin is 51% to 60% bioavailable and is absorbed primarily from the small intestine. It does not undergo hepatic metabolism and is eliminated unchanged in the urine. It is not recommended for patients with renal impairment. Monotherapy with metformin is effective; however, when combined with a sulfonylurea, the drug is useful in cases that are resistant to oral antidiabetics (hypoglycemics). Metformin therapy should be withheld for 48 hours before and after the patient undergoes IV contrast dye, because lactic acidosis or acute renal failure may develop.

Alpha-Glucosidase Inhibitors: Acarbose (Precose) and Miglitol (Glyset)

Acarbose acts by inhibiting the digestive enzyme in the small intestine that is responsible for the release of glucose from complex carbohydrates (CHO) in the diet. By inhibiting alpha glucosidase, absorption of complex CHO is delayed. Acarbose has no demonstrated systemic effects and is not absorbed into the body in significant amounts. It does not cause hypoglycemic reaction. Acarbose is intended for use in patients who do not achieve results with diet alone. Miglitol, like acarbose, inhibits alpha glucosides. Miglitol is absorbed from the GI tract. This drug will not cause hypoglycemia, but if taken with a sulfonylurea or insulin, hypoglycemia could occur.

Thiazolidinediones

Pioglitazone (Actos) and rosiglitazone (Avandia) were considered safe thiazolidinedione drugs. However, in 2007 a warning was added to the Avandia packaging after the FDA issued a statement that Avandia users may be at greater risk for heart attack and possibly death. Both drugs are contraindicated in symptomatic heart disease and Classes III and IV congestive heart failure. These two drugs can be prescribed for monotherapy or combined with other oral antidiabetic drugs. Pioglitazone can be taken in combination with sulfonylurea or insulin, and rosiglitazone may be combined with metformin (Prototype Drug Chart 52-3). These drugs do not induce hypoglycemic reactions if taken alone. They decrease insulin resistance and improve blood glucose control.

Meglitinides

Repaglinide (Prandin) and nateglinide (Starlix) are classified as meglitinide oral antidiabetic agents. They stimulate the beta cells to release insulin. The action of repaglinide and nateglinide is similar to that of sulfonylureas. These agents can be used alone or in combination with metformin for patients with type 2 diabetes mellitus. They are short-acting antidiabetic drugs. Repaglinide and nateglinide should not be

PROTOTYPE DRUG CHART 52-3

Metformin

Drug Class

Metformin: biguanide
Trade Names: Glucophage, Glucophage XR
Pregnancy Category: B

Dosage

A: PO: Initial: 500 mg 1-3 times/d with or shortly after meals; increase dose gradually; *max:* 2550 mg/d
A: PO: ER: 500 mg/d with evening meal; *max:* 2,000 mg/d

Contraindications

Hypersensitivity, diabetic ketoacidosis, radiographic contrast administration, concurrent infection, hepatic or renal dysfunction, cardiopulmonary insufficiency, alcoholism
Caution: Pregnancy, lactation

Drug-Lab-Food Interactions

Drug: ACE inhibitors, ARBs, calcium channel blockers, beta-blockers, procainamide, quinidine, digoxin, furosemide, alcohol, cimetidine, ranitidine, azole antifungals, trimethoprim, vancomycin, and quinine may potentiate hypoglycemia; iodinated contrast dyes, nicotine, morphine, triamterene, thiazide diuretics may cause lactic acidosis or acute kidney failure
Lab: Altered liver function tests
Food: Green tea may lead to hypoglycemia

Pharmacokinetics

Absorption: 51%-60% absorbed
Distribution: PB: 0%
Metabolism: t½: 6-17 h
Excretion: Primarily in urine

Pharmacodynamics

PO: Onset: UK
Peak: 1-3 h
Duration: UK

Therapeutic Effects/Uses

To control hyperglycemia in type 2 diabetes mellitus
Mode of Action: Increases binding of insulin to receptors, improves tissue sensitivity to insulin, increases glucose transport to skeletal muscles and fatty tissues, decreases glucose production in liver by reducing gluconeogenesis, and reduces glucose absorption from intestines

Side Effects

Dizziness, fatigue, headache, agitation, bitter or metallic taste, anorexia, nausea, vomiting, diarrhea, weight loss

Adverse Reactions

Lactic acidosis; malabsorption of amino acids, vitamin B_{12}, and folic acid
Life-threatening: Lactic acidosis

A, Adult; *d,* day; *h,* hour; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *ER,* extended-release; *t ½,* half-life; *t.i.d.,* three times a day; *UK,* unknown.

prescribed for patients with liver dysfunction because of possible decreased liver metabolism rate. More of the drug could remain in the body, which may cause a hypoglycemic reaction.

Incretin Modifier

The oral antidiabetics sitagliptin phosphate (Januvia) and saxagliptin (Onglyza) are classified as incretin modifiers (also called *dipeptidyl peptidase-4 [DPP-4] inhibitors* and *gliptins*) for treatment of type 2 diabetes mellitus. The action of DPP-4 inhibitors is to increase the level of incretin hormones, increase insulin secretion, and decrease glucagon secretion to reduce glucose production. This incretin modifier is used as adjunct treatment with exercise and diet to reduce both fasting and postprandial plasma glucose levels.

Guidelines for Oral Antidiabetic (Hypoglycemic) Therapy for Type 2 Diabetes

The following are criteria for the use of oral antidiabetic drugs:

- Onset of diabetes mellitus at age 40 years or older
- Diagnosis of diabetes for <5 years
- Normal weight or overweight
- Fasting blood glucose ≤200 mg/dL
- <40 units of insulin required per day
- Normal renal and hepatic function

Other Antidiabetic Agents

Exenatide (Byetta) and liraglutide (Victoza) are in a classification of antidiabetic drugs known as *incretin mimetics* (also called *glucagon-like peptide-1 agonists* or *GLP-1 agonists*). These drugs improve beta-cell responsiveness, which improves glucose control in people with type 2 diabetes mellitus. The actions of exenatide and liraglutide are to enhance insulin secretion, increase beta-cell responsiveness, suppress glucagon secretion, slow gastric emptying, and reduce food intake. Exenatide and liraglutide are not a substitute for insulin and should not be administered to patients with type 1 diabetes mellitus, diabetic ketoacidosis, severe renal dysfunction, or severe GI disease. Common adverse effects that occur with exenatide include headache, dizziness, jitteriness, nausea, vomiting, and diarrhea. Exenatide is administered by injectable prefilled pens in twice-a-day dosing and has significantly improved A_{1c} levels and weight loss in many patients. Liraglutide is given subcutaneously once a day.

Nursing Process
Patient-Centered Collaborative Care

Oral Antidiabetics

Assessment

- Identify drugs patient currently takes. Aspirin, alcohol, sulfonamides, oral contraceptives, and monoamine oxidase inhibitors (MAOIs) increase hypoglycemic effect; a decrease in oral antidiabetic drug may be needed. Glucocorticoids (cortisone), thiazide diuretics, and estrogen increase blood glucose.
- Note vital signs and blood glucose levels. Report abnormal findings.
- Determine patient's knowledge of diabetes mellitus and use of oral antidiabetics.

Nursing Diagnoses

- Risk for injury related to side effect of visual disturbances
- Imbalanced nutrition, more than body requirements, related to excessive food intake
- Deficient knowledge related to lack of exposure to teaching about taking adequate food with oral antidiabetics

Planning

- Patient's blood sugar will be within normal serum levels (70 to 110 mg/dL).
- Patient will adhere to prescribed diet, blood testing, and drug.
- Patient will demonstrate knowledge of oral hypoglycemics and their importance.

Nursing Interventions

- Determine vital signs. Oral antidiabetics increase cardiac function and oxygen consumption, which can lead to cardiac dysrhythmias.
- Administer oral antidiabetics with food to minimize gastric upset.
- Monitor blood glucose levels, and report changes. Reference value is 60 to 100 mg/dL for blood glucose and 70 to 110 mg/dL for serum glucose.
- Prepare a teaching plan based on patient's knowledge of health problems, diet, and drug therapy.

Patient Teaching

General

- Advise patient that hypoglycemic (insulin) reaction can occur when taking an oral hypoglycemic drug, especially sulfonylureas. This drug stimulates the release of insulin from beta cells of the pancreas. Oral antidiabetics are not insulin. Normally, patients with diabetes mellitus type 1 do not have functioning beta cells and should not take oral antidiabetics, only insulin. Sulfonylureas are prescribed for patients with diabetes mellitus type 2.
- Teach patient to recognize symptoms of hypoglycemic reaction (headache, nervousness, sweating, tremors, and rapid pulse) and hyperglycemic reaction (thirst, increased urine output, sweet, fruity breath odor).
- Explain that insulin might be needed instead of oral antidiabetic drug during stress, surgery, or serious infection. Blood glucose levels are usually elevated during stressful times.

- Tell patient about necessity for compliance to diet and drug.
- Advise patient to carry MedicAlert card, tag, or bracelet indicating health problem and antidiabetic dosage.

Self-Administration

- Teach patient how to check blood glucose level with a glucometer. Patient should record and report abnormal results.

Side Effects

- Advise patient to report side effects such as vomiting, diarrhea, and rash.

Diet

- Caution patient not to ingest alcohol with antidiabetic drugs to avoid hypoglycemic reaction.
- Advise patient taking oral antidiabetics to eat prescribed diet on schedule. Delaying or missing a meal can cause hypoglycemia.
- Explain use of orange juice, sugar-containing drinks, or hard candy when hypoglycemic reaction begins. Explain importance of reporting such problems to health care provider.
- Direct patient to take oral antidiabetics with food to decrease gastric irritation.

Cultural Considerations

- Respect patient's cultural beliefs and alternative methods for treating diabetes and elevated blood glucose levels. Discuss safety of methods and use of oral antidiabetic drugs to correct problem (an interpreter may be necessary). If patient takes an oral antidiabetic drug to decrease blood glucose level, emphasize importance of checking blood glucose levels daily or as indicated. Hypoglycemic reaction can result from increased doses of oral antidiabetic agents and insufficient dietary intake.

Evaluation

- Evaluate effectiveness of drug therapy by noting if blood glucose levels are within accepted range.
- Determine patient knowledge of diabetic regimen.

Pramlintide acetate (Symlin) is another antidiabetic agent in a classification called *amylin analogue*, approved by the FDA for adults with type 1 and type 2 diabetes mellitus. The primary purpose of pramlintide is to improve postprandial glucose control in diabetic patients who are using insulin but are unable to achieve and maintain glucose control. The actions of pramlintide are to suppress glucagon secretion, slow gastric emptying, and modulate appetite by inducing satiety. Suppression of glucagon secretion reduces postprandial hepatic glucose for approximately 3 hours. By slowing gastric emptying, the absorption rate of glucose is reduced. Satiety promotes reduced food intake. Common adverse effects include dizziness, anorexia, nausea, vomiting, and fatigue. Pramlintide is administered by subcutaneous injection before meals in the abdomen or thigh; it is never given in the arm.

Hyperglycemic Drugs

Glucagon

Glucagon is a hyperglycemic hormone secreted by alpha cells of the islets of Langerhans in the pancreas. Glucagon increases blood sugar by stimulating glycogenolysis (glycogen breakdown) in the liver. It protects the body cells, especially those in the brain and retina, by providing the nutrients and energy needed to maintain body function.

Glucagon is available for parenteral use (subQ, IM, and IV). It is used to treat insulin-induced hypoglycemia when other methods of providing glucose are not available. For example, the patient may be semiconscious or unconscious and unable to ingest sugar-containing products. Patients with diabetes who are prone to severe hypoglycemic reactions (insulin shock) should keep glucagon in the home, and family members should be taught how to administer subQ or IM injections during an emergency hypoglycemic reaction. The blood glucose level begins to increase within 10 minutes after administration.

Diazoxide

Oral diazoxide (Proglycem), which is chemically related to thiazide diuretics, increases blood sugar by inhibiting insulin release from the beta cells and stimulating release of epinephrine (Adrenalin) from the adrenal medulla. This drug is not indicated for hypoglycemic reaction; rather, it is used to treat chronic hypoglycemia caused by hyperinsulinism due to islet cell cancer or hyperplasia. The parenteral form of diazoxide (Hyperstat) is prescribed for malignant hypertension. Hypotension does not usually occur with oral diazoxide.

Diazoxide has a long half-life and is highly protein-bound. Its onset of action is 1 hour, and the duration of action is 8 hours. Most of the drug is excreted unchanged in urine.

CRITICAL THINKING CASE STUDY

TC, a 32-year-old patient, was diagnosed with diabetes mellitus after the birth of her first child; her blood sugar level was 180 mg/dL. Her serum glucose level has been maintained within the normal range with metformin (Glucophage) 500 mg/day.

1. Why was TC, at 32 years of age, taking an oral antidiabetic drug instead of insulin?
2. Metformin is indicated for what type of diabetes mellitus? When should metformin not be taken?
3. Why should TC monitor her blood sugar using a home glucometer?

Two years later, TC became pregnant again. Metformin was discontinued, and Humulin N insulin 25 units was prescribed. Since the birth of her second child, she has remained on Humulin N 25 units/day.

4. Give a possible reason why the health care provider changed the antidiabetic drug to insulin when TC became pregnant.
5. Humulin N is similar to what other type of insulin? How do these two types differ?
6. Give the onset, peak, and duration of action for Humulin N insulin. When is an insulin reaction most likely to occur with Humulin N?
7. What are the pros and cons for TC to receive Humulin 70/30 insulin?
8. What are the signs and symptoms of hypoglycemic reaction?
9. What should be included in patient teaching?

TC asks the nurse if she can take metformin again instead of insulin, because she is eating the "right foods."

10. What is the nurse's best response?

NCLEX STUDY QUESTIONS

1. A patient is diagnosed with type 2 diabetes mellitus. The nurse is aware that which statement is true about this patient?
   a. Patient is most likely a teenager.
   b. Patient is most likely a child younger than 10 years.
   c. Heredity and obesity are major causative factors.
   d. Viral infections contribute most to disease development.
2. Antidiabetic drugs are designed to control signs and symptoms of diabetes mellitus. The nurse primarily expects a decrease in which?
   a. Blood glucose
   b. Fat metabolism
   c. Glycogen storage
   d. Protein mobilization
3. A patient is to receive insulin before breakfast, and the time of breakfast tray delivery is variable. The nurse knows that which insulin should not be administered until the breakfast tray has arrived and the patient is ready to eat?
   a. Humulin N
   b. lispro (Humalog)
   c. glargine (Lantus)
   d. Humulin R
4. A patient is receiving a daily dose of Humulin N insulin at 7:30 AM. The nurse expects the peak effect of this drug to occur at which time?
   a. 8:15 AM
   b. 10:30 AM
   c. 5:00 PM
   d. 11:00 PM
5. A patient is prescribed glipizide (Glucotrol). The nurse knows that which side effects and adverse effects may be expected? (Select all that apply.)
   a. Tachypnea
   b. Tachycardia
   c. Increased alertness
   d. Increased weight gain
   e. Visual disturbances
   f. Hunger
6. A nurse is teaching a patient how to recognize symptoms of hypoglycemia. Which symptoms should be included in the teaching? (Select all that apply.)
   a. Headache
   b. Nervousness
   c. Bradycardia
   d. Sweating
   e. Thirst
   f. Sweet breath odor
7. A patient is newly diagnosed with type 1 diabetes mellitus and requires daily insulin injections. Which instruction should the nurse include in the teaching of insulin administration?
   a. Teach family members how to administer glucagon by injection when the patient has a hyperglycemic reaction.
   b. Instruct the patient about the necessity for compliance with prescribed insulin therapy.
   c. Teach the patient that hypoglycemic reactions are more likely to occur at the onset of action time.
   d. Instruct the patient in the care and handling of the insulin container and syringe.

Answers: 1, c; 2, a; 3, b; 4, c; 5, b, e, f; 6, a, b, d; 7, b.

UNIT XVIII

Reproductive and Gender-Related Agents

This unit comprises six chapters that focus on reproductive and gender-related drugs. Chapters 53, 54, 55, and 56 address agents specifically associated with female health and disorders. Drugs used throughout the female reproductive cycle, including pregnancy and preterm labor, are comprehensively discussed in Chapter 53, Female Reproductive Cycle I: Pregnancy and Preterm Labor Drugs. Chapter 54, Female Reproductive Cycle II: Labor, Delivery, and Preterm Neonatal Drugs, covers labor and delivery. Chapter 55, Postpartum and Newborn Drugs, focuses on the pharmacology of the postpartum and neonatal period. Chapter 56, Drugs for Women's Reproductive Health and Menopause, details the variety of oral contraceptive products and the drugs used to treat menopausal discomforts. Chapter 57, Drugs for Men's Health and Reproductive Disorders, describes androgens and anabolic steroids, antiandrogens, and other drugs related to male reproductive health and disorders. Chapter 58, Drugs for Disorders in Women's Health, Infertility, and Sexually Transmitted Infections, concludes this unit with a discussion of drugs used to treat specific reproductive health issues, including endometriosis, premenstrual syndrome, infertility, and sexually transmitted infections.

FEMALE REPRODUCTIVE PROCESSES

The uterus is a pear-shaped, hollow, very muscular organ located in the pelvic cavity between the rectum and the bladder; it is connected to the vagina by the cervix (Figure XVIII-1). Three distinct layers compose the uterine wall: the outer layer (perimetrium); the muscular middle layer (myometrium); and the inner mucosal layer (endometrium).

The myometrium is a network of involuntary (smooth) muscles divided into three layers, with the muscles of each layer configured in different patterns. For example, the outer muscles are arranged longitudinally to assist with cervical effacement (thinning and shortening) and to expel the fetus at the time of delivery. Muscles in the middle layer are arranged in a figure-8 design. These muscles are extremely important in the control of bleeding (hemostasis). Blood vessels are threaded throughout these muscles, and when a contraction occurs, the vessels are compressed, creating a hemostatic effect. Circular muscle fibers are found in the area of the internal os and help control its sphincter. These circular muscles keep the fetus contained in the uterus for the normal gestational period. It is these muscles that stretch (dilate) the cervix to a diameter of 10 cm during labor. When all three muscle layers work together during labor, contractions cause cervical dilation and descent and delivery of the infant.

The Menstrual Cycle

The reproductive cycle is hormonally controlled by interactions between the endocrine and reproductive systems. The hypothalamus secretes gonadotropin-releasing hormone (Gn-RH), which stimulates the anterior pituitary gland to synthesize and release follicle-stimulating hormone (FSH) and luteinizing hormone (LH). These gonadotropins stimulate the ovaries to produce estrogen and progesterone, respectively.

In most women, the menstrual cycle lasts 28 days (range of 22 to 34 days). The ovarian hormones estrogen and progesterone regulate the cycle, which has three ovarian phases: follicular, ovulatory, and luteal. Endometrial phases occur simultaneously with these ovarian phases.

The *follicular phase* occurs during days 1 to 14 of the cycle. Days 1 to 6 of this period constitute the menstrual phase, and days 7 to 14 constitute the proliferative phase. During the total 14-day period, FSH increases and follicles begin to mature within the ovary. One graafian follicle from the group matures and swells by days 10 to 13, ruptures on day 14, and releases the ovum to the fallopian tube. The *ovulatory phase* occurs on day 14 when the ovum is released. The *luteal phase* occurs from days 15 to 28 and includes the secretory phase of the endometrial cycle. During this period, estrogen and progesterone are produced by the ovarian corpus luteum (the ruptured graafian follicle), reaching peak levels 8 days into the phase. Changes occur in the endometrium for optimal implantation of a fertilized ovum. FSH and LH levels decrease, mediated by dopamine, norepinephrine, and serotonin. Estrogen and progesterone are withdrawn immediately before menstruation, and the endometrial prostaglandin level increases. The cycle begins anew with the follicular phase. In cycles that are nonovulatory, hormonal secretion of estrogen, FSH, and LH is erratic; there is also an alteration in the usual amount of progesterone. These physiologic alterations become the basis for planning and implementing pharmacologic interventions.

MALE REPRODUCTIVE PROCESSES

There are three male reproductive processes: spermatogenesis, or sperm production; regulation of male sexual functioning; and sexual intercourse.

Male Reproductive Anatomy and Physiology

The anatomy of the male sexual organs is depicted in Figure XVIII-2. The external reproductive organs include the penis, the scrotum, and the testes. The penis consists of three cylindrical bodies of erectile tissue: two corpora cavernosa and the corpus spongiosum. With sexual excitement, the vascular spaces fill with blood to produce an erection (Figure XVIII-3).

The scrotum has two compartments, each of which holds a testis, epididymis, and spermatic cord. The spermatic cord supports the testis and includes the vas deferens, blood vessels, nerves, and muscle fibers.

Each testis contains seminiferous tubules in which spermatogenesis occurs. The sperm then move into the epididymis. This leads into the vas deferens, the source of about 20% of ejaculate, or semen. On either side of the prostate gland, a seminal vesicle empties seminal fluid into the ampulla. Seminal fluid contains fructose to provide energy for the sperm, prostaglandins, fibrinogen, and a sperm-activating factor.

The contents of the ampulla and the seminal vesicles empty into an ejaculatory duct that leads through the body of the prostate to empty into the urethra. Prostatic fluid, which constitutes about 20% of semen, empties from the prostate gland into the ejaculatory duct. The urethra carries semen to its distal end. The urethral glands along the length of the urethra and the bulbourethral glands near the prostatic end of the urethra supply the urethra with mucus. The bulbourethral glands secrete alkaline preejaculatory fluid to protect sperm from the acidity of the urethra.

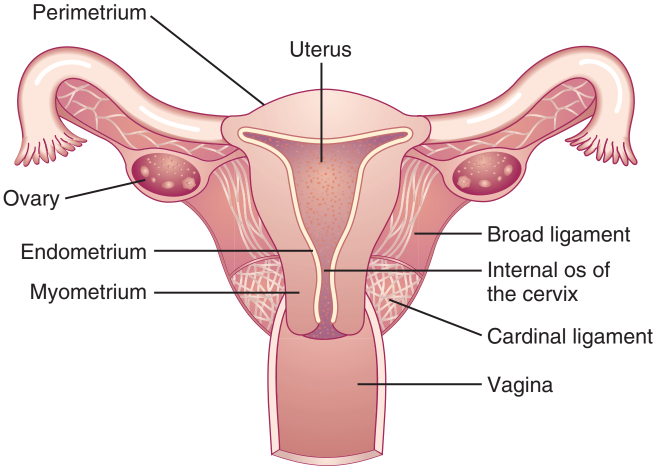

FIGURE XVIII-1 Anatomy of the female reproductive system.

Hormonal Regulation of Male Reproductive Functioning and Spermatogenesis

Gn-RH from the hypothalamus stimulates the anterior pituitary gland to secrete two major gonadotropins, LH and FSH, in both men and women. LH stimulates the interstitial Leydig cells of the testes to mature and produce testosterone. There is a direct relationship between the amount of circulating LH and the amount of testosterone produced. Testosterone is also produced to a lesser extent in the adrenal cortex and in the ovaries of women.

In men, FSH stimulates the Sertoli cells to begin conversion of spermatids into mature sperm. In addition, the Sertoli cells are stimulated to secrete estrogens, which may promote spermatogenesis. For spermatogenesis to be complete, testosterone must be secreted simultaneously by the Leydig cells and diffused into the seminiferous tubules.

Testosterone is the precursor of two classes of sex steroids: 5-alpha-reduced androgens and estrogens. The net effect of endogenous androgens is the sum of the effects of the 5-alpha-reduced metabolite dihydrotestosterone and its estrogen derivative, estradiol. Most testosterone is loosely bound by plasma protein and circulates for 15 to 30 minutes before it is fixed to target tissues or metabolized. Most testosterone fixed to target cells is then converted to its active form, dihydrotestosterone.

The rate of testosterone production is controlled by a negative feedback loop. With increased testosterone, the hypothalamus decreases production of Gn-RH (Figure XVIII-4). With sperm production, the Sertoli cells release a hormone called *inhibin,* which suppresses FSH production by the anterior

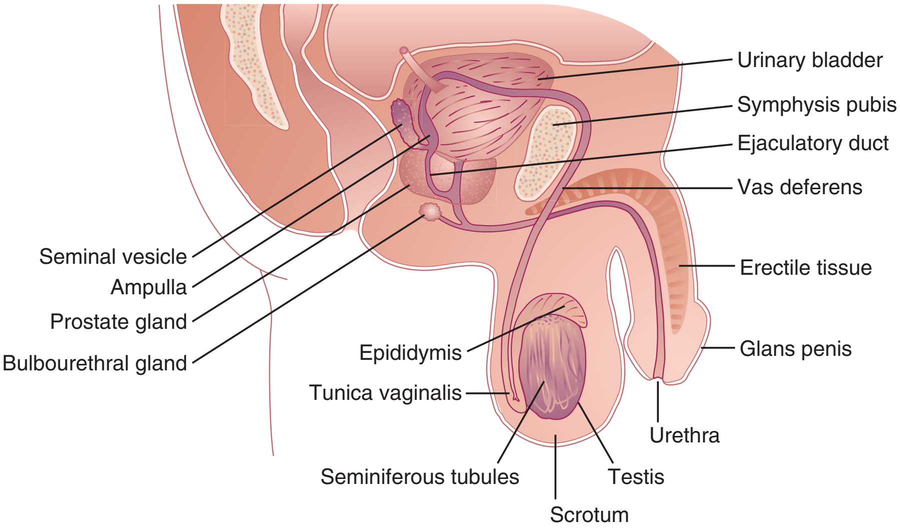

FIGURE XVIII-2 Anatomy of the male reproductive system.

pituitary gland, maintaining a constant rate of spermatogenesis. It is not known how, before puberty, the brain stimulates the hypothalamus to begin Gn-RH secretion, but if the brain is not intact, this may not occur.

Sexual Function

The human sexual response cycle consists of five phases: desire, excitement, plateau, orgasm, and resolution. Sexual desire is the stimulus that causes an individual to initiate or be receptive to sexual activity. During the excitement phase, the man experiences penile erection. Men are incapable of engaging in sexual intercourse without this arousal. The plateau phase is characterized by genital enlargement, mucous secretion, generalized muscle tension, hyperventilation, tachycardia, and increased blood pressure. During the orgasmic phase, the vas deferens, seminal vesicles, ejaculatory duct, and penile urethra contract three or four times over a few seconds, which causes the man to ejaculate. During resolution, there is a refractory period in which pelvic vasocongestion declines and generalized muscle relaxation takes place.

Central artery
Corpus spongiosum
Urethra

FIGURE XVIII-3 Erectile tissue of the penis.

PROCESS OF FERTILIZATION

Fertilization, or conception, occurs when a sperm penetrates an ovum, usually in the distal third of the fallopian tube.

In a single ejaculation, between 200 and 400 million spermatozoa are deposited in the vagina. Sperm move up the female reproductive tract using the flagellar motion of their tails. It takes an average of 4 to 6 hours for the sperm to reach the distal fallopian tube. Semen contains prostaglandins that may enhance uterine motility to facilitate sperm migration. The ciliary action of the fallopian tubes enhances migration of the ovum to the uterus and of sperm toward the ovary.

Uterine enzymes capacitate the sperm by altering their glycoprotein coat. In an acrosomal reaction, the sperm release the enzyme hyaluronidase, which breaks through the outer layer of the ovum. The moment one sperm penetrates the ovum, a chemical reaction occurs that blocks other sperm from entering. Cellular division begins immediately in what is now called the *zygote,* or fertilized egg.

After 3 days, the zygote enters the uterus. It has now differentiated into an inner solid mass of cells, the blastocyst, and an outer layer, the trophoblast. Progesterone secreted by the corpus luteum of the ovary maintains a favorable uterine environment to nourish the blastocyst until implantation in the uterine lining occurs. The blastocyst develops into the embryo and the amniotic membrane, whereas the trophoblast develops into the chorionic membrane and the fetal side of the placenta. The maternal portion of the placenta develops under the site of the blastocyst's implantation. The placenta is the structure through which oxygen, nutrients, and metabolic wastes pass between the maternal and fetal circulations for the duration of pregnancy. The placenta begins to function by the fourth week of pregnancy. Within the first 8 weeks of pregnancy, organ systems are differentiated, and it is during this period that the fetus is most vulnerable to teratogens. Growth of the fetus throughout pregnancy depends on adequate oxygenation and nutrition, the metabolic environment, freedom from infection, and integrity of the mother's reproductive tract.

OBJECTIVES

- Explain potential health-promoting and detrimental effects of substances ingested by the patient during the prenatal period.
- Describe the drugs that alter uterine muscle contractility.
- Discuss drug therapy used during preterm labor to decrease the incidence or severity of neonatal respiratory dysfunction.
- Compare systemic and regional medications for pain control during labor.
- Describe the drugs used in gestational hypertension.
- Describe the nursing process, including patient teaching, associated with the drugs used during pregnancy and preterm labor.

PHYSIOLOGY OF PREGNANCY

Because pregnancy is a change in the normal physiology of the body, the normal and expected pharmacokinetics and pharmacodynamics of medications also change. Changes in drug action during pregnancy include (1) effect of circulating steroid hormones on the liver's metabolism of drugs; (2) reduced gastrointestinal motility and increased gastric pH; (3) increased glomerular filtration rate and increased renal perfusion, resulting in more rapid renal excretion of drugs; (4) expanded maternal circulating blood volume, resulting in dilution of drugs; and (5) alteration in the clearance of drugs in later pregnancy, resulting in a decrease in serum and tissue concentrations of drugs. Because of alterations in the normal physiology of the body, medications should not be ordered in lower doses with longer intervals between doses because of the possibility of subtherapeutic serum and tissue concentrations.

Other factors, such as late pregnancy and labor, can alter the half-lives of some medications. Antibiotics and barbiturates are examples of medications that have shorter half-lives during pregnancy. In contrast to later pregnancy, labor can actually increase the half-life of some medications (e.g., analgesics, hypnotics, antibiotics); it is believed that drug clearance decreases as a result of transient reduced blood flow associated with uterine contractions when the patient is in a supine position. There is also concern about the effects of certain disease states on medication during pregnancy. Disorders like diabetes mellitus and gestational hypertension may result in decreased renal perfusion and subsequent drug accumulation.

The placenta plays an important role in drug use and metabolism. It was once thought that the placenta played a barrier role, but it is now known that the placenta has an important function as the organ of exchange for numerous substances, including medications. It allows some substances to transfer quickly or slowly between mother and fetus, depending on variables such as (1) maternal and fetal blood flow; (2) molecular weight of the substance (low–molecular-weight substances cross more readily than do high–molecular-weight substances; most medications have a low molecular weight, so they readily cross the placenta); (3) degree of ionization of the drug molecule (the more ionized the molecule, the less readily it crosses the placenta); (4) degree of protein-binding (highly bound drugs do not cross readily); (5) metabolic activity of the placenta (the metabolic activity can biotransform molecules into active metabolites that can affect the fetus); and (6) maternal dose.

Guidelines for medication administration during pregnancy must include determination that the benefits of prescribing a drug outweigh potential short- or long-term risks to the maternal-fetal system. Careful selection and monitoring for the minimum effective dose for the shortest interval in the therapeutic range are required. Consideration must be given to alterations related to the physiologic changes of pregnancy.

Liver metabolism of medications is much slower in the fetus as a result of immaturity of the liver. Therefore, drug metabolism is slower in the fetus, which can cause more evident or longer drug effects than on the mother. The degree of fetal exposure to a drug and its breakdown products are more important to fetal outcome than the rate at which the drug is transported to the fetus.

The mechanisms by which drugs cross the placenta are analogous to the way in which drugs infiltrate breast tissue. Lactation results in increased blood flow to the breasts, and drugs accumulate in adipose breast tissue through simple diffusion. Long-term effects on infants from drugs in breast milk are unknown, but medications that accumulate in breast milk are known, and the breastfeeding patient should be alerted to the potential accumulation.

Despite prenatal education, public service announcements, and information conveyed through the media, use of legal and illicit drugs by pregnant patients continues. Additionally, health care providers may prescribe drugs for maternal disorders that indirectly affect the fetus. However, it is important to note that most drugs required by pregnant patients can be used safely. It is estimated that half the medications taken by pregnant patients are over-the-counter (OTC) drugs. The drugs most commonly ingested during pregnancy are iron supplements and vitamins, antiemetics, antacids, stool softeners, nasal decongestants, mild analgesics, and antibiotics. Pregnant patients should be discouraged from using OTC medications until they consult with their health care provider or pharmacist.

Drugs conclusively determined to be safe for the embryo are limited in number. Clinical trials can be resources for reliable drug information; however, it is unethical to test for the safety and efficacy of medications in pregnant patients. Animal studies are required during drug testing, but the information obtained from such studies is difficult to extrapolate to humans. Case reports used for such information can be of limited value because they usually present isolated occurrences. A commonly used source of information about drug safety in pregnancy is the U.S. Food and Drug Administration's (FDA) category system. The categories were created to assist with safe prescribing and informed counseling of the pregnant patient requiring medication.

There are many known **teratogens** (substances that cause developmental abnormalities). Timing, dose, and duration of exposure are of crucial importance in determining the teratogenicity of a given drug. In humans, the teratogenic period begins 2 weeks after conception. During the first 2 weeks, the embryo is not susceptible to teratogenesis. At this time of development, exposure to teratogens may result in either death of the embryo or minor cellular damage without congenital birth defects. From 2 gestational weeks through the next 10 weeks is the period of organogenesis (development of major structures and organs). Table 53-1 shows adverse effects of selected illicit substances commonly used during pregnancy.

TABLE 53-1 GENERAL ADVERSE EFFECTS OF SUBSTANCES COMMONLY ABUSED DURING PREGNANCY

SUBSTANCE	MATERNAL EFFECTS	FETAL EFFECTS*
Alcohol (high risk: 6 oz or more/d)	1 oz (2 drinks) absolute alcohol 2 times/wk: increased risk for spontaneous abortion (2-4 times)	Fetal alcohol syndrome (FAS): mild to moderate mental retardation, altered facial features, growth retardation, low birth weight, small head circumference, hypotonia, and poor motor coordination. Full FAS seen only in some children; others display only fetal alcohol effect (FAE).
Caffeine	2 cups increase epinephrine concentrations after 30 min and decrease intervillous blood flow with potential for spontaneous abortion (dosage and gestational period related)	Excess consumption (>6-8 cups/d) likely toxic to embryo. No evidence of teratogenicity
Cocaine	48-h clearance via urine. Increased incidence of spontaneous abortion in first trimester. Continued use or sporadic use related to premature delivery and abruptio placentae secondary to placental vasoconstriction and hyperextension	4-5 d clearance time via urine of newborn because of liver immaturity and lack of cholinesterase. Intrauterine growth retardation, decreased head circumference, intrauterine cerebral infarction. No true withdrawal syndrome, but increased irritability, hyperreflexia, and tremulousness. Deficient organization and interactive abilities. By month 4, still exhibits hypertonicity, tremulousness, and impaired motor development. By month 6, effects may appear self-limiting, but long-term research is needed.
Heroin	First-trimester spontaneous abortion, premature delivery, inadequate maternal calorie and protein intake	Neonatal meconium aspiration syndrome; decreased weight and length through postnatal month 9 (weight and length catch up by month 12); smaller head circumference (with no catch-up); impaired interactive abilities (hard to console and engage); inconsistent behavioral responses; increased tremulousness and irritability
Marijuana	Heavy use (5 or more marijuana cigarettes per week): shortened gestation (<37 wk); may hasten delivery through uterine stimulation	No higher incidence of serious birth defects caused solely by marijuana. Higher incidence of meconium passage during labor
Tobacco/nicotine	Degenerative placental lesions with areas of poor oxygen exchange; higher incidence of abruptio placentae; placenta previa, vaginal bleeding during pregnancy; possible PROM; possible amnionitis; less likely to choose to breastfeed	Short stature, smaller head and arm circumferences; no increase in mortality rate or congenital anomalies (some evidence of increased oral clefts); increased respiratory infections beyond perinatal period; possible shorter attention span beyond perinatal period
Methadone	If taken before pregnancy, will need to slow detoxification during pregnancy and decrease dose 5 mg every 2 wk. Do not detoxify before week 14 of gestation because of increased risk for spontaneous abortion	Smaller weight and length through postnatal month 9 (catch up on weight and length by month 12); smaller head circumference (no catch-up); withdrawal-induced fetal distress if mother detoxifies after 32 weeks' gestation
Barbiturates	CNS depression; lethargy; sleepiness; subtle mood alterations and impaired judgment/fine-motor skills for 24 h No known inhibitory effect on uterine tone or contractility. Selective anticonvulsant activity without anesthesia effects may warrant use in pregnancy for seizure disorders Active labor with imminent delivery is a contraindication, because no antagonist drug is available	Rapidly cross placenta; with excessive use/high doses cause CNS depression, leading to respiratory depression, hyperactivity, and decreased sucking reflex
Tranquilizers	Dose-dependent; toxic reactions include ataxia, syncope, vertigo, and drowsiness; control of acute eclamptic seizures during labor	Benzodiazepine (diazepam [Valium]) use in first trimester not associated with oral clefts or other anomalies. Chronic third trimester or labor exposure in high doses associated with hypotonia, hypothermia, hyperbilirubinemia, and poor sucking reflex. Effects may be enhanced if systemic analgesics also given to mother. Fetal effects are prolonged.

*Children with prenatal drug exposure scored significantly lower on measures of language, school readiness skills, impulse control, and visual attention span/sequencing at age 5 years when compared with nondrug-exposed children from a comparable environment.

CNS, Central nervous system; *d,* day; *h,* hour; *min,* minute; *PROM,* premature rupture of fetal membranes; *wk,* week; <, less than; >, greater than.

THERAPEUTIC DRUG AND HERBAL USE IN PREGNANCY

The most common indications for use of medications during pregnancy are nutritional supplementation with iron, vitamins, and minerals and treatment of nausea and vomiting, gastric acidity, and mild discomforts, but caution must be exercised (Herbal Alert 53-1).

HERBAL ALERT 53-1

Pregnancy

Herbal preparations are not generally recommended during pregnancy. In particular, the following herbs should be avoided:

- Feverfew and sage are emmenagogues that stimulate blood flow in the uterus.
- Kava kava decreases platelets.
- Dong quai, garlic, and gingko biloba increase bleeding when used with anticoagulants.
- Ginseng may decrease the action of anticoagulants.
- St. John's wort has mutagenic effects on cells of the developing embryo and fetus.

Iron

During pregnancy, approximately twice the normal amount of iron is needed to meet fetal and maternal daily requirements: 27 mg/day during pregnancy compared with 18 mg/day for nonpregnant patients 19 to 30 years of age. Supplementation with iron is not generally necessary until the second trimester, when the fetus begins to store iron; the goal is to prevent maternal iron-deficiency anemia, not to supply the fetus. The fetus is adequately supplied through the placenta, although the mother is deficient. Greatest iron demand occurs in the third trimester: 22.4 mg/day compared with 6.4 mg/day and 18.8 mg/day for the first and second trimesters, respectively.

Although a normal diet generally provides the 18-mg recommended daily allowance (RDA) of iron for nonpregnant patients, nonanemic pregnant patients are usually instructed to supplement using a dosage that provides 60 mg of elemental iron; anemic patients should receive 120 mg of elemental iron. The elemental iron content of the most common iron salts includes ferrous sulfate 20% (300 mg of ferrous sulfate is equivalent to 60 mg elemental iron), exsiccated ferrous sulfate 30%, ferrous gluconate 12%, and ferrous fumarate 33%. The estimated net iron cost of pregnancy is approximately 800 to 1000 mg. This iron cost is calculated as 250 mg basal losses + 320 mg deposition in fetal and placental tissue + 500 mg increased hemoglobin mass + 350 mg iron loss in blood associated with delivery. Patients are advised to continue supplements for 6 weeks postpartum.

Pregnant patients generally have decreased hematocrit early in the third trimester. Those with levels less than 30% will have their supplemental iron dosages increased and complete blood counts with platelet and ferritin measured. In those with true iron-deficiency anemia, response to iron supplementation is usually noted in 5 to 7 days, with a modest reticulocytosis and an increase in hemoglobin in 3 weeks. No teratogenic effects have been reported with physiologic doses. In contrast, increasing evidence has associated prenatal iron supplementation with glucose impairment and hypertension in midpregnancy. Many OTC and prescription iron products (Table 53-2) are available in varying dosages, which differ in the amount of elemental iron contained in the form of iron salts.

TABLE 53-2 IRON PRODUCTS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
ferrous sulfate (Fer-In-Sol, Feosol, Fero-Gradumet, Mol-Iron, Fer-Iron)	A: PO: 300-600 mg/d in divided doses 325 mg/d sufficient to meet needs of non–iron-deficient pregnant patient; with iron deficiency, administer 325 mg 2-3 times/d	Hematinic; for iron-deficiency anemia; prophylaxis for iron deficiency in pregnancy. Replaces iron stores needed for RBC development Absorption PO is 5%-30% in intestines; therefore GI side effects. Toxic reactions include pallor, hematemesis, shock, cardiovascular collapse, and metabolic acidosis. Contraindicated in patients with hypersensitivity and peptic ulcer. Decreased absorption of tetracycline, penicillamine, and antacids; increased absorption with ascorbic acid; decreased absorption with eggs, milk, coffee, tea. Can reduce availability of zinc from diet Take at bedtime to avoid GI upset. Absorption promoted when taken with orange juice or other vitamin C source. Use straw (elixir); swallow tab/cap whole; take with water on empty stomach. Sit upright 30 min after dose to decrease reflux. Increase fluids, activity, and dietary bulk. Keep out of reach of children Peak reticulocytosis: 5-10 d; hemoglobin values increase: 2-4 wk Pregnancy category: A; PB: UK; $t\frac{1}{2}$: UK; onset: 3-10 d; duration: 3-4 mo
ferrous gluconate (Fergon)	A: PO: 200-600 mg t.i.d.	Same as above
ferrous fumarate (Fumasorb, Femiron, Feostat, Fumerin)	A: PO: 200 mg t.i.d./q.i.d.	Same as above

A, Adult; *cap,* capsule; *d,* day; *GI,* gastrointestinal; *min,* minute; *mo,* month; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *RBC,* red blood cell; $t\frac{1}{2}$, half-life; *t.i.d.,* three times a day; *tab,* tablet; *UK,* unknown; *wk,* week.

Adverse Reactions

Common side effects of iron supplements include nausea, constipation, black tarry stools, gastrointestinal irritation, epigastric pain, vomiting, discoloration of urine, and diarrhea.

Nursing Implications

Liquid forms can cause temporary tooth discoloration and therefore should be diluted and administered through a plastic straw. Iron supplements are best absorbed on an empty stomach and when administered with water or juice (concurrent administration of 200 mg ascorbic acid/vitamin C per 30 mg of elemental iron increases the absorption of iron). However, if gastric irritation does occur, administer with food. Iron supplementation may inhibit the absorption of several medications, and appropriate separation of doses should be followed (e.g., iron supplementation should be administered 2 hours before or 4 hours after antacids). Additional examples of medications that may require separation in dose include levodopa, levothyroxine (Levothroid, Synthroid), methyldopa, penicillamine (Cuprimine, Depen), quinolones, and tetracyclines. For the same reasons, do not administer iron with milk, cereal, tea, coffee, or eggs.

Folic Acid

Folic acid supplementation as part of preconception planning improves the outcome of pregnancy. During pregnancy, folic acid (vitamin B_9, folate) is needed in increased amounts. Folic acid deficiency early in pregnancy can result in spontaneous abortion or birth defects, especially neural tube defects (failure of the embryonic neural tube to close properly, leading to spina bifida or skull and brain malformations). Deficiency of folic acid may also contribute to premature birth, low birth weight, and premature separation of the placenta *(abruptio placentae)*. In the United States, approximately 4,000 pregnancies a year are affected by neural tube defects. Controlled clinical trials have demonstrated that folic acid supplementation can reduce this incidence by as much as 50%.

Normally, the RDA for folic acid is 180 mcg, but the United States Preventive Services Task Force recommends that women who are planning pregnancy take a supplement containing 0.4 mg to 0.8 mg of folic acid 1 month before and for the first 2 to 3 months after conception. The American College of Obstetricians and Gynecologists (ACOG) recommends that all women of childbearing age ingest 400 mcg of folic acid daily for birth defect prevention (during pregnancy, the RDA rises to 600 mcg). The reasoning behind the ACOG's recommendation is the high incidence of unplanned and unrecognized pregnancies.

The neural tube closes within the first 4 weeks of pregnancy (18 to 26 days after conception); therefore, it is important that women consume the recommended amounts of folic acid per day. For patients who have had a pregnancy that was affected by a neural tube defect, higher doses of folic acid are recommended: 4 mg starting 1 to 3 months before conception.

The recommended amount should be ingested from folate-enriched foods and supplementation, because the amount of naturally occurring folic acid ingested in foods varies from day to day, and the folic acid from these sources is not well absorbed. Examples of folate-enriched foods are bread, cornmeal, rice, pasta, and cereal.

Adverse Reactions

Side effects of folic acid supplementation are not common but include allergic bronchospasm, rash, pruritus, erythema, and general malaise. Patients should be aware that folic acid supplementation may cause urine to turn more intensely yellow.

Multiple Vitamins

Prenatal vitamin preparations are routinely recommended for pregnant women. These preparations generally supply vitamins A, D, E, C, B complex, B_{12}, iron, calcium, and other minerals. The role of prenatal vitamins in preventing congenital defects (e.g., cleft lip or palate, limb defects) has not been determined.

Inadequate nutrition cannot be rectified through supplements alone; vitamins are used most effectively by the body when taken with meals, and calories and protein are not supplied by supplements.

Megadoses of vitamins and minerals during pregnancy will not improve health and may cause harm to the pregnant patient, the fetus, or both. Large doses of vitamin A can be teratogenic, and excessive ingestion of vitamins D, E, and K may also be toxic.

Drugs for Minor Discomforts of Pregnancy

The average prenatal patient uses three drugs during pregnancy, two of which are vitamin and mineral supplements. Drug ingestion is most likely during the first and third trimesters, when the discomforts of pregnancy tend to be most bothersome. Many complaints associated with pregnancy are related to the gastrointestinal (GI) tract (nausea and vomiting, heartburn, constipation). The etiology of nausea and vomiting is unclear. Physiologically, nausea is purported to be related to increased human chorionic gonadotropin (hCG) levels during pregnancy. Increased progesterone during pregnancy, which relaxes smooth muscle, contributes to heartburn and constipation. The physiologic reason is that elevated female sex hormones during pregnancy change the motility of the GI tract. Additionally, the enlarging uterus displaces the bowel.

Nausea and Vomiting

Nausea and vomiting (morning sickness) during early pregnancy are major complaints for most (about 88%) pregnant patients, but *hyperemesis gravidarum* (severe nausea and vomiting that may require hospitalization for hydration and nutrition) occurs with much lower incidence (1% to 3%). Nonpharmacologic measures to decrease nausea and vomiting include (1) eating crackers, dry toast, or other carbohydrates before rising; (2) avoiding high-fat or highly seasoned foods; (3) eating small, frequent meals; (4) drinking fluids between rather than with meals; (5) drinking apple juice or flat soda between meals; (6) eating a high-protein bedtime snack; (7) stopping smoking; and (8) taking an iron supplement at bedtime. These measures work well for most patients, but if vomiting is severe, fluid replacement and pharmacologic measures may be necessary.

The FDA has approved one drug for morning sickness, doxylamine succinate and pyridoxine hydrocholoride (Diclegis). Antiemetic drug studies often find that affected patients rate even placebo agents as helpful. Table 53-3 lists drugs used for management of nausea and vomiting during pregnancy with their dosages, uses, and considerations.

Many patients may use ginger to help treat nausea and vomiting associated with pregnancy, but there is insufficient evidence of its safety and efficacy during pregnancy. Ingestion of large amounts may act as an abortifacient. Studies suggest that ginger can be safely used in moderation, but as with all medications and herbal supplements, encourage the pregnant patient to discuss use of ginger with her health care provider. Ginger can increase the risk for bleeding, particularly if the patient has a history of bleeding disorder. Research has demonstrated safe dosage levels up to 1,000 mg/day in pregnancy; therefore, pregnant patients are advised not to take more than 1,000 mg/day.

Women who experience nausea and vomiting may experience gastric distress if they are also taking supplemental iron; taking the iron supplement with food or at bedtime, or temporarily suspending therapy, may help. Prenatal vitamins should be taken at the time of day the patient is least likely to experience emesis, because a high incidence of nausea and vomiting is associated with prenatal vitamins. For patients with continued iron-induced gastric distress, many health care providers recommend taking two children's chewable multivitamins with iron. Salting food to taste may help replace vomited chloride; foods rich in potassium and magnesium may also help replace lost nutrients.

Patients whose symptoms persist and who experience weight loss and dehydration may require intravenous (IV) rehydration, including replacement of electrolytes and vitamins. Antiemetic therapy (probably with phenothiazines) may be used, and ondansetron (Zofran) may be administered in severe cases of *hyperemesis gravidarum*.

Heartburn

Heartburn *(pyrosis)* is a burning sensation in the epigastric and sternal regions that occurs with reflux of acidic stomach contents. The incidence of heartburn during pregnancy is common, up to 80%. Pregnant patients experience decreased motility in the GI tract as a result of the normal increase in the hormone **progesterone.** Progesterone also relaxes the cardiac sphincter (the sphincter leading into the stomach from the esophagus, also called the *lower esophageal sphincter),* making reflux activity *(reverse peristalsis)* more likely. Digestion and gastric emptying are slower than in the nonpregnant state. Heartburn is common when a pregnant patient sits or lies down soon after eating a normal meal, only to have her gravid uterus exert upward pressure on her stomach, causing increased reflux activity and the perception of hyperacidity. Heartburn is a disorder of the second and third trimesters of pregnancy.

Nonpharmacologic measures are preferred in the management of heartburn. These include (1) limiting the size of meals; (2) avoiding highly seasoned or greasy foods; (3) avoiding gas-forming foods (e.g., cabbage, onions); (4) eating slowly and chewing thoroughly; (5) avoiding citrus juices; (6) drinking adequate fluids, but not with meals; and (7) avoiding reclining immediately after eating.

Antacids should be considered first-line therapy if the patient does not respond to nonpharmacologic therapy. The antacids of choice for the pregnant patient include nonsystemic low-sodium products (those considered dietetically sodium-free) containing aluminum and magnesium (in the form of hydroxide) in combination. Discourage long-term use or large doses of magnesium antacids, because fetal renal, respiratory, cardiovascular, and muscle problems may result. Sucralfate (Carafate) is likely safe during pregnancy, because the drug is not systemically absorbed. Calcium carbonate antacid preparations may be avoided in pregnancy because of the rebound effect following acid neutralization. TUMS are frequently taken by pregnant patients for heartburn, but because TUMS are calcium based, excessive use may contribute to constipation.

Most patients do not realize that remedies commonly used by nonpregnant patients (e.g., baking soda, antacids such as Alka-Seltzer) can be harmful during pregnancy. Selection of the wrong antacid can result in diarrhea, constipation, or electrolyte imbalance. A combination of nonpharmacologic measures and minimal use of safe antacids should effectively meet the pregnant patient's needs.

Liquid antacids are the preparations most commonly used in pregnancy because of their uniform dissolution, rapid action, and greater activity. Tablets are also acceptable, particularly for convenience, provided they are thoroughly chewed and the patient maintains adequate fluid intake.

Histamine$_2$ receptor antagonists can be used during pregnancy, but only if their use is recommended by a health care provider and initial treatment with antacids has failed. The teratogenicity of these medications is unknown; however, cimetidine (Tagamet), ranitidine (Zantac), famotidine (Pepcid), and nizatidine (Axid) have received the FDA's pregnancy category B rating. H$_2$ receptor antagonists work by competitively and reversibly binding to the histamine receptors of the parietal cells, causing a reduction in gastric acid secretion. The onset of action is generally in 1 hour and can persist for 6 to 12 hours.

There is even less experience with the use of proton pump inhibitors. These medications work to suppress gastric acid secretion by inhibiting the proton pump on the surface of the parietal cells. With the release of omeprazole (Prilosec OTC), pregnant patients may wonder about its use for heartburn during pregnancy. Encourage patients to discuss the options with their health care provider. Currently, the use of

TABLE 53-3 DRUGS FOR MANAGEMENT OF NAUSEA AND VOMITING DURING PREGNANCY*

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Vitamin		
pyridoxine (B_6)	PO: Up to 25 mg t.i.d.	Coenzyme for various metabolic functions, including metabolism of proteins, carbohydrates, and fats. Side effects are rare and include headache, nausea, somnolence, and sensory neuropathy Pregnancy category: A; absorbed in jejunum and metabolized primarily in the liver.excreted in urine; $t_{1/2}$: 0.5 d; Peak plasma time: 5-6 h (pyridoxine)
Antihistamines		
meclizine (Antivert)	PO: 20-50 mg/d	Blocks CTZ, which acts on vomiting center; available OTC. Sites of action are labyrinth and CNS. Side effects include dizziness, drowsiness, dry mouth and nose, blurred vision, diplopia, urinary retention, urticaria, rash, and headache. Cardiovascular effects include hypotension, palpitations, and tachycardia Contraindicated in patients with hypersensitivity to drug or any component Contraindicated in patients with closed-angle glaucoma Increased effect of alcohol, tranquilizers, and narcotics Pregnancy category: B; metabolized in liver and excreted unchanged in feces and as metabolites in urine. $t_{1/2}$: 6 h; Onset: 1-2 h; Duration: 8-24 h
doxylamine (Unisom) (unlabeled use)	PO: 25 mg (½ tab b.i.d.)	Considered mild, available OTC. Competes with free histamine for binding at H_1 receptor sites. If pyrixodine (B_6) 25 mg is not effective, health care provider may suggest docylamine 25 mg and pyridoxine 25 mg t.i.d. (1 tab h.s. and ½ tab in morning and afternoon). May cause sedative effects, thick bronchial secretions, drowsiness, dizziness, headache, constipation, abdominal pain with cramps, blurred vision, decreased coordination, and dry mouth Contraindicated in patients with acute asthma and possibly hypertension, cardiovascular disorders, and hyperthyroidism Caution: Take only under direction of health care provider. Pregnancy category: A; $t_{1/2}$:1.25 h; Onset: 1-2 h
Antihistamine Plue Vitamin B_6 Analog		
doxylamine succineate (10 mg)/pyridoxine 10 mg (Diclegis)	PO: 2 tablets h.s. If dose controls symptoms the next day, continue taking 2 tablets at h.s. If symptoms persist into the afternoon of day 2, take 2 tablets at h.s., then 3 tablets starting on day 3 (1 tablet in the morning and 2 tablets at h.s.). If 3 tablets adequately control symptoms on day 4, continue taking 3 tablets daily. If symptoms persist, take 4 tablets starting on day 4 (1 tablet in morning, 1 tablet in mid-afternoon, and 2 tablets at h.s.	Mechanism of action: Unknown Side effects: Somnolence, falls or other accidents in combined use with CNS depressants, including alcohol Warnings/precautions: Contraindicated in women with known hypersensitivity to doxylamine succinate, other ethanolamine derivative antihistamines, and pyridoxine hydrochloride. Monoamine oxidase (MAO) inhibitors intensify and prolong the adverse central nervous system effects of Diclegis. Has anticholinergic properties and should be used with caution in women with asthma, increased intraocular pressure, narrow angle glaucoma, stenosing peptic ulcer, pyloroduodenal obstruction, and urinary bladder-neck obstruction. Nursing mothers should not use. Pregnancy category: A; absorbed in the jejunum and primarily metabolized in the liver; doxylamine is primarily excreted by the kidney; $t_{1/2}$: 0.5 h; Peak plasma time: 7-8 h (doxylamine); 5-6 h (pyridoxine)

Continued

TABLE 53-3 DRUGS FOR MANAGEMENT OF NAUSEA AND VOMITING DURING PREGNANCY—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Phenothiazines		
promethazine (Phenergan)	PO/IV/IM/PR: 12.5-25 mg q4-6h PRN	Blocks postsynaptic mesolimbic dopaminergic receptors in brain; exhibits strong alpha-adrenergic blocking effect and depresses release of hypothalamic and hypophyseal hormones; competes with histamine for H_1 receptor Side effects include dizziness, drowsiness, excitation, fatigue, insomnia, photosensitivity reactions, nausea, vomiting, and constipation Contraindicated in patients with hypersensitivity to drug or any component, CNS depression, or coma Use caution in patients with cardiovascular disease; not recommended for subQ or intraarterial administration; injection may contain sulfites, which may cause allergic reaction Pregnancy category: C; $t_{1/2}$: 9-16 h; Onset: IM: 20 min; IV: 3-5 min; Duration: 2-6 h
Anticholinergics		
scopolamine	PO/IM/IV/subQ: 0.3-0.65 mg q4-6h	Antagonizes histamine and serotonin Side effects include confusion, drowsiness, headache, fatigue, dry skin, constipation, vomiting, and bloated feeling. Cardiovascular side effects include orthostatic hypotension, ventricular fibrillation, tachycardia, and palpitations Contraindicated in patients with hypersensitivity to drug or any component and those with narrow-angle glaucoma, acute hemorrhage, GI or GU obstruction, tachycardia secondary to cardiac insufficiency, and myasthenia gravis Use with caution in patients with hepatic or renal impairment Pregnancy category: C; Onset: IM: 0.5-1 h; Duration: 4-6 h
Prokinetic Agents		
metoclopramide (Reglan)	PO: 10-15 mg q.i.d. 30 min a.c.	Blocks dopamine receptors in CTZ of CNS; causes enhanced motility and accelerated gastric emptying without stimulating secretions Side effects include restlessness, drowsiness, diarrhea, weakness, and insomnia Contraindicated in patients with hypersensitivity to drug or any component; GI obstruction, perforation, or hemorrhage; pheochromocytoma; or history of seizure disorder Pregnancy category: B; $t_{1/2}$: 4-7 h; Onset: 0.5-1 h; Duration: 1-2 h
Other		
trimethobenzamide (Tigan, T-Gen)	200 mg PR q6-8h	Obscure action; may be mediated through CTZ. Does not inhibit direct impulse to vomiting center. Chemically classified as ethanolamine derivative. Contraindicated in patients with cardiac dysrhythmias, narrow-angle glaucoma, asthma, and pyloroduodenal obstruction. Rectal doses of drug are more unpredictable Side effects include drowsiness, headache, blurred vision, diarrhea, depression, hypotension, muscle cramps, allergic reactions, extrapyramidal symptoms, and blood dyscrasias Contraindicated with benzocaine and in patients with hypersensitivity to drug. Use suppository form in neonates or preterm infants Caution: Do not use in patients with acute emesis to avoid masking symptoms Drug interactions with phenothiazines/barbiturates, belladonna Pregnancy category: C; $t_{1/2}$: UK; Onset: PO/PR: 10-40 min; IM: 15-35 min; Duration: 3-4 h

TABLE 53-3 DRUGS FOR MANAGEMENT OF NAUSEA AND VOMITING DURING PREGNANCY—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
ondansetron (Zofran)	8 mg PO/IV every 8 h	Antiemetic; selective 5-HT$_3$ receptor antagonist. Blocks serotonin, both peripherally on vagal nerve terminals and centrally in CMZ of CNS Side effects include headache, constipation, diarrhea, malaise/fatigue Contraindicated in patients with hypersensitivity to drug or other selective 5-HT$_3$ antagonists Caution: Use as scheduled, not PRN. Use with caution in patients who have congenital/medical conditions that cause prolonged QT interval or take medications that prolong QT interval Drug interactions: drugs altering activity of liver enzymes Pregnancy category: B; t½: 3-6 h; Onset: 30 min; Duration: 4-8 h

omeprazole is limited to cases in which the benefits of therapy far outweigh the risks.

Table 53-4 presents medications for heartburn commonly used during pregnancy.

Constipation

Constipation is a frequent occurrence during pregnancy. Its cause may be related to hormonal changes—specifically progesterone, which decreases GI motility. As with heartburn, nonpharmacologic treatments for constipation should be tried first. These include (1) increased fluid intake, (2) increased dietary fiber intake, and (3) moderate physical exercise. If these methods do not work, treatment is indicated, and the safest agents are bulk-forming preparations containing fiber (e.g., Metamucil), because they are not systemically absorbed. Also, docusate sodium (Colace), a stool softener, would be appropriate as first-line treatment during pregnancy. Agents that should be reserved for occasional use include milk of magnesia, magnesium citrate, lactulose (Constulose, Enulose), sorbitol, bisacodyl (Correctol, Dulcolax), and senna (Senokot, Ex-Lax).

Castor oil should be avoided during pregnancy, because it can stimulate uterine contractions. Mineral oil should also be avoided, because it can reduce the absorption of fat-soluble vitamins like vitamin K. (Low levels of vitamin K in the neonate can result in hemorrhage.)

Pain

Through week 26 of pregnancy, headaches resulting from hormonally induced body changes, sinus congestion, or eye strain are quite common. It is not unusual for the pregnant patient to experience backaches, joint pains, round ligament pain (resulting in mild abdominal aches and twinges), and pain from minor injuries. Nonpharmacologic pain relief measures should be tried initially, including rest; calming environment; relaxation exercises; alteration in routine; mental imagery; ice packs; warm, moist heat; postural changes; correct body mechanics; and changes in footwear.

Acetaminophen

Acetaminophen (Tylenol), a para-aminophenol analgesic, is a pregnancy category B drug. It is the most commonly ingested nonprescription drug during pregnancy. Acetaminophen may be used during all trimesters of pregnancy in therapeutic doses on a short-term basis for its analgesic and antipyretic effects. The drug is a weak prostaglandin inhibitor and does not have significant antiinflammatory effects. Prototype Drug Chart 26-1 lists the pharmacologic data for acetaminophen.

Pharmacokinetics The rate of absorption of acetaminophen is dependent on the rate of gastric emptying. Acetaminophen is 20% to 50% protein-bound and crosses the placenta during pregnancy; it is also found in low concentrations in breast milk. Acetaminophen is partially hepatically metabolized into inactive metabolites; however, a highly active metabolite (N-acetyl-*p*-benzoquinone) produced when the drug is taken in large doses can have potential liver and kidney toxicity. The half-life is 2 to 3 hours. There is no concrete evidence of fetal anomalies associated with the use of acetaminophen, and no adverse effects have been noted in breastfed infants of patients who used the drug while pregnant or breastfeeding.

Pharmacodynamics The maximum daily dose of acetaminophen (Tylenol) is 4000 mg per day, and the use of acetaminophen during pregnancy should not exceed 12 tablets per 24 hours of a 325-mg formulation (regular strength) or 8 tablets per 24 hours of a 500-mg (extra strength) formulation (because of the potential for kidney and liver toxicity). The drug should be taken at 4- to 6-hour intervals. Onset of effects after oral ingestion is within 10 to 30 minutes; peak action occurs at 1 to 2 hours; duration is from 3 to 5 hours.

Manufacturers of OTC products containing acetaminophen have lowered the maximum daily dose recommendation to 3,000 mg due to the frequency of overdose with acetaminophen. One reason for the high frequency of overdose is that patients may take multiple OTC products that all contain acetaminophen.

TABLE 53-4 **OVER-THE-COUNTER ANTACIDS COMMONLY USED IN PREGNANCY**

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
aluminum hydroxide (Amphojel)	A: PO: As directed*	Contains 320 mg of aluminum hydroxide gel per 300-mg tab or per 5 mL; ANC 8; contains saccharin and sorbitol. OTC preparation. For heartburn secondary to reflux Neutralizes gastric acidity Side effects include constipation; adverse reactions include dehydration, hypophosphatemia (long-term use), GI obstruction Decreased effects with tetracycline, phenothiazine, benzodiazepines, isoniazid, digoxin; follow dose with water Pregnancy category: C; PB: UK; t½: UK; Onset: 15-30 min; Peak: 0.5 h; Duration: 1-3 h
magnesium hydroxide and aluminum hydroxide with simethicone (Mylanta Extra Strength Liquid, Almacone)	40-125 mg PO q.i.d. after meals and h.s.; up to 500 mg/d	Mylanta Extra Strength Liquid: Each 5 mL contains 400 mg aluminum hydroxide, 400 mg magnesium hydroxide, 40 mg simethicone, parabens, saccharin, sorbitol, and 2 mg sodium OTC preparation Almacone tabs: Each tab contains 200 mg aluminum hydroxide, 200 mg magnesium hydroxide, and 20 mg simethicone OTC preparation. Tabs must be chewed thoroughly. Same as above with addition of antiflatulence action. Neutralizes gastric acidity and antiflatulent. Adverse effects include acid rebound. Aluminum-based antacids may cause constipation, while magnesium-based antacids have a laxative effect. Aluminum and magnesium–based combination antacids are given to balance the constipation and laxative effects. Do not administer magnesium-based antacids in patients with renal disease. Drug interactions: Concurrent administration with digoxin, indomethacin (Indocin), or iron salts may decrease absorption of these drugs. Concurrent administration with chlordiazepoxide hydrochloride decreases rate of chlordiazepoxide absorption. Decreased pharmacologic effect with antacids and benzodiazepines, captopril, corticosteroids, fluoroquinolones, histamine H_2 antagonists, hydantoins, ketoconazole, penicillamine (Cuprimine, Depen), phenothiazines, salicylates, and ticlopidine (Ticlid). Increased pharmacologic effect with levodopa, sulfonylureas, and valproic acid. Pregnancy category: C; PB: UK; t½: UK

*Dosage recommendations for antacid preparations should be clarified by the health care provider; however, as a general rule, no more than 12 tablets or 12 tsp should be taken in a 24-hour period, depending on the strength of the product. Major side effects are change in bowel habits (diarrhea or constipation), nausea, vomiting, alkalosis, and hypermagnesemia. Antacids figure in numerous drug interactions because of their increased action on gastric pH and their propensity to bind with other drugs to form poorly absorbed complexes. Antacids should not be taken within 2 hours of taking iron, digitalis products, tetracycline, or phenothiazine.

A, Adult; *ANC,* acid-neutralizing capacity (per tablet or 5 mL); *d,* day; *GI,* gastrointestinal; *h,* hour; *min,* minute; *OTC,* over-the-counter; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *tab,* tablet; *tsp,* teaspoon; *UK,* unknown.

Most patients without preexisting renal or hepatic disease tolerate acetaminophen well. Patients with hypersensitivity to the compound should not use it. Acetaminophen should be used cautiously in patients who are at risk for infection because of the possibility of masking signs and symptoms. The most frequent adverse reactions are skin eruptions, urticaria, unusual bruising, erythema, hypoglycemia, jaundice, hemolytic anemia, neutropenia, leukopenia, pancytopenia, and thrombocytopenia.

Aspirin and Ibuprofen

Aspirin, a salicylate, is classified as a mild analgesic. Aspirin is a pregnancy category C drug (which changes to category D if full-dose aspirin is used in the third trimester). It is a prostaglandin synthetase inhibitor with antipyretic, analgesic, and antiinflammatory properties. Teratogenic effects have not been shown conclusively, but the risk for anomalies is perceived to be small.

Aspirin can inhibit the initiation of labor and actually prolong labor through its effects on uterine contractility; therefore, its use is not recommended during pregnancy. Aspirin use late in pregnancy is also associated with greater maternal blood loss at delivery, and there may be increased risk for anemia in pregnancy and of antepartum hemorrhage. Hemostasis is affected in the newborn whose mother ingested aspirin during the last 2 months of pregnancy (even without use during the week of delivery). Platelets are unable to aggregate to form clots, and it appears that this is not a reversible effect after delivery; the infant must wait for its own bone marrow to produce new platelets. (Refer to Chapter 26 for more information on aspirin.)

Ibuprofen is classified as a pregnancy category C drug (which changes to category D if used in the third trimester). If taken late in pregnancy, it may cause premature closure of the ductus arteriosus. Ibuprofen is a prostaglandin synthetase inhibitor with antipyretic, analgesic, and antiinflammatory properties. Bleeding risks are similar to those reported with aspirin, though ibuprofen causes less inhibition of platelet aggregation than aspirin formulations.

Antidepressant Drugs

Exposure to antidepressant drugs and depressive disorders have both been associated with adverse birth outcomes. Adverse outcomes have included low birth weight, small for gestational age, preterm delivery, and increased neonatal irritability and decreased attentiveness. Use of selective serotonin reuptake inhibitors (SSRIs) in pregnancy is associated with low birth weight and small for gestational age infants. Preterm delivery (before 37 gestational weeks) is significantly higher in patients taking SSRIs and tricyclics. Although tricyclic antidepressant use in pregnancy has not been associated with structural malformations, in utero exposure has been linked to neonatal jitteriness and irritability. *Poor neonatal adaptation,* a term for transient symptoms like tachypnea, irritability, hypoglycemia, and weak cry, has been reported in neonates exposed to SSRIs in late pregnancy. Options for treatment for pregnant patient include psychotherapy alone or in conjunction with pharmacologic therapy as determined by the health care provider.

Nursing Process
Patient-Centered Collaborative Care

Antepartum Drugs

Assessment
- Gather comprehensive medical and drug (illicit, herbal, nonpharmacologic, and pharmacologic) history.
- Obtain baseline vital signs.
- Identify patients at risk for substance abuse, and collaborate with other professionals to plan strategies to minimize risks.
- Assess drug history to determine if antacid use will interfere with absorption.
- Review history of aspirin use when admitting patient in labor. If aspirin has been used, alert staff and monitor for increased bleeding.
- Ascertain any medical history of alcoholism, liver disease, viral infection, or renal deficiencies. Acetaminophen should be used cautiously in these patients.
- Assess Group B colonization in pregnancy for treatment and neonatal prevention.

Nursing Diagnoses
- Deficient knowledge related to health maintenance needs during pregnancy
- Deficient knowledge related to potential adverse fetal outcomes from exposure to teratogens

Planning
- Patient will use or avoid various drugs during pregnancy as advised.
- Patient will discuss drug and herb use with health care provider or pharmacist before use.

Nursing Interventions
General
- Be cognizant that drug use may be part of multiple-substance abuse and may also involve maternal-neonatal infections.
- Stress the importance of prenatal care, and discuss patient's fears about health care professionals and concerns about legal action in the event of substance abuse.

Specific
- Advise on nonpharmacologic and pharmacologic measures to relieve common pregnancy discomforts.
- Refer patient to tobacco, alcohol, or drug treatment program if appropriate.
- Counsel patient on nutritional and therapeutic supplements needed during pregnancy.
- Monitor hemoglobin/hematocrit of prenatal patients per agency protocol.

Iron
- Question patient about nausea, constipation, and bowel habit changes if taking iron preparations.
- Give diluted liquid iron preparation through a plastic straw to prevent discoloration of teeth. Giving iron with orange juice, which is high in ascorbic acid, enhances absorption.
- Store iron in a light-resistant container.
- Recognize that patient may have false-positive result of occult blood in stool if taking iron.

Patient Teaching
General
- Advise patient that tobacco, alcohol, and heavy caffeine use may have adverse effects on the fetus.
- Encourage patient to speak with health care provider before taking drugs (illicit, OTC, prescribed) secondary to teratogenic potential.
- Counsel patient planning to breastfeed to discuss drugs (illicit, OTC, prescribed) with health care provider.

Aspirin/Acetaminophen/Ibuprofen
- Advise patient to take acetaminophen rather than aspirin during pregnancy; aspirin and ibuprofen are particularly contraindicated during the third trimester.

- Counsel patient against ingesting multiple OTC pain or cough/cold preparations, because many OTC products contain acetaminophen.

Antepartum Drugs

- Advise patient not to take nonsteroidal antiinflammatory drugs (NSAIDs) with acetaminophen.
- Advise patient not to take NSAIDS after second trimester.

Caffeine/Alcohol/Nicotine

- Advise patient to limit coffee ingestion to 1 to 2 cups per day and to limit other sources of caffeine (tea, cola, chocolate, certain drugs).
- If caffeine is allowed by health care provider, encourage patient to space limited caffeine intake evenly throughout day, because caffeine passes readily to fetus, who cannot metabolize it. Caffeine can decrease intervillous placental blood flow.
- Advise patient to use decaffeinated products or dilute caffeinated products.
- Suggest that patient use herbal products carefully because of occasionally harmful ingredients (see Herbal Alert 53-1).
- If patient plans to breastfeed, explain that 1% of caffeine consumed will appear in breast milk within 15 minutes. Therefore, although one cup of coffee is fine, it is not wise to drink several cups of coffee in succession; excess caffeine will accumulate in the infant's tissues. The infant lacks enzymes to adequately clear the caffeine for 7 to 9 months after birth.
- Advise pregnant patient not to drink alcohol, because no safe level has been determined, and that even minimal exposure may result in fetal alcohol effect, and moderate/excessive exposure may result in fetal alcohol syndrome.
- Advise patient that smoking can cause loss of nutrients such as vitamins A and C, folic acid, cobalamin, and calcium. Tobacco use may contribute to shortened gestation and low-birth-weight infants.

Antacids

- Advise patient that antacids should not be taken within 1 hour of taking an enteric-coated tablet, because the acid-resistant coating may dissolve in the increased alkaline condition of the stomach, and the medication will not be released in the intestine as intended. Stomach upset may result.
- Instruct patient to store antacid liquid suspension at room temperature (or place under refrigeration to improve palatability), not to freeze it, and to shake bottle well before ingesting.

Iron

- Advise patient about dietary sources of iron, including red meat, nuts and seeds, wheat germ, spinach, broccoli, prunes, and iron-fortified cereal.
- Explain to patient that if supplemental iron is taken between meals, increased absorption (and also increased side effects) may result. Taking iron 1 hour before meals is suggested. Give with orange juice or water, but not with milk or antacids.

Self-Administration for Iron and Antacids

- Advise patient to swallow iron tablets whole, not crush them. Liquid iron preparations are taken with a plastic straw to avoid staining teeth.
- Caution patient not to take antacids with iron, because antacids impair absorption and are generally discouraged during pregnancy. Iron and antacids should be taken 2 hours apart if both are prescribed.

Side Effects for Iron and Antacids

- Advise patient to keep iron tablets away from children. Iron tablets look like candy, and death has been reported in small children who have ingested 2 g or less of ferrous sulfate. Iron is a leading cause of fatal poisoning in children.
- Advise patient that there may be a change in bowel habits when taking antacids. Aluminum and calcium carbonate products can cause constipation, whereas magnesium products can cause diarrhea. Many antacids contain a combination of ingredients to reduce adverse effects.

Cultural Considerations

- Consider cultural food practices and beliefs in regard to the use of prenatal vitamins. For example, in Mexico, some may view vitamins as a "hot food" that should not be ingested during pregnancy.

Evaluation

- Evaluate effectiveness of prescribed drug therapy. Report side effects.
- Evaluate patient's understanding of possible effects on fetus from maternal use of drugs (prescribed, OTC, and illicit) and tobacco or alcohol.

DRUGS THAT DECREASE UTERINE MUSCLE CONTRACTILITY

Preterm Labor

Preterm labor (PTL) is labor that occurs between 20 and 37 weeks of pregnancy, involving a fetus with an estimated weight between 500 and 2499 g. Regular contractions occur at less than 10-minute intervals over 30 to 60 minutes and are strong enough to result in 2-cm cervical dilation and 80% effacement. PTL occurs in approximately 8% to 10% of all pregnancies. Preterm infants who survive very early delivery have significant physiologic challenges to overcome, so PTL that progresses to preterm delivery accounts for most perinatal morbidity and mortality (excluding fetuses with anomalies) in the United States.

Although PTL has no single known cause, certain risk factors have been identified: maternal age younger than 18 years or older than 40 years, low socioeconomic status, previous history of preterm delivery (17% to 37% chance of recurrence), intrauterine infections (e.g., bacterial vaginosis), polyhydramnios, multiple gestation, uterine anomalies, antepartum hemorrhage, smoking, drug use, urinary tract infections, and incompetent cervix. Attempts to arrest PTL are contraindicated in (1) pregnancy of less than 20 weeks' gestation (confirmed by ultrasound), (2) bulging or premature rupture of membranes (PROM), (3) confirmed fetal death or anomalies incompatible with life, (4) maternal hemorrhage and evidence of severe fetal compromise, and (5) chorioamnionitis.

Nonpharmacologic treatment measures for PTL include bed rest, hydration (ingestion of six to eight glasses of fluids daily or more, IV fluid bolus), pelvic rest (no sexual intercourse or douching), and screening for intrauterine and urinary tract infections. Patient assessment includes uterine activity (frequency, duration, and intensity), vaginal bleeding or discharge, and fetal monitoring.

Tocolytic Therapy

When patients in true PTL (with cervical change) have no contraindications, they become candidates for **tocolytic therapy** (drug therapy to decrease uterine muscle contractions) using beta$_2$-adrenergic receptor agonists (e.g., terbutaline) or, more commonly, the calcium antagonist magnesium sulfate. Other tocolytics less commonly used are calcium channel blockers (e.g., nifedine, [Procardia]) and prostaglandin inhibitors (e.g., indomethacin [Indocin]). Calcium channel blockers prevent the influx of calcium ions, resulting in relaxation of the myometrium. Prostaglandin or cyclooxygenase (COX, or prostaglandin synthase) is the enzyme responsible for converting acrachidonic acid and increasing available intracellular calcium. Therefore, prostaglandin inhibitors limit the available calcium for uterine contractions. With concerns regarding the safety profiles of beta-sympathomimetics and magnesium sulfate comes an increased interest in the latter two drug categories for tocolysis. The goals in tocolytic therapy are to (1) interrupt or inhibit uterine contractions to create additional time for fetal maturation in utero, (2) delay delivery so antenatal corticosteroids can be delivered to facilitate fetal lung maturation, and (3) allow safe transport of the patient to an appropriate facility if required. The use of progesterone, administered vaginally or intramuscularly to prevent preterm birth, is under investigation. Table 53-5 lists the drugs used to decrease preterm uterine contractions and their dosages, uses, and considerations.

Beta-Sympathomimetic Drugs

Beta-sympathomimetic drugs act by stimulating beta$_2$-receptors on uterine smooth muscle. The frequency and intensity of uterine contractions decrease as the muscle relaxes. Terbutaline is used in the late second and early third trimesters, more commonly limited to a single dose therapy as an acute tocolytic. It is approved for medicinal use but not specifically as a tocolytic. Terbutaline can effectively decrease uterine contractions; however, use of terbutaline in the United States has waned with increased awareness of its effects on maternal and fetal cardiovascular systems and free placental passage. The U.S. Food and Drug Administration (FDA) is recommending that *injectable* terbutaline should not be used in pregnant women for prevention or prolonged treatment (beyond 48 to 72 hours) of preterm labor secondary to the risk of maternal cardiac problems and death (*www.fda.gov/drugs/drugsafety/ucm243539.htm*).

SAFETY: Preventing Medication Errors

Do not confuse…

- **methylergonovine** (Methergine) (used to stimulate uterine contractions in the prevention and treatment of postpartum hemorrhage) with **terbutaline sulfate** (used to decrease uterine contractions in preterm labor). These drugs have the same packaging but opposite actions. Both are amber ampules with amber plastic packaging and colored neckbands wrapped in foil. Do not store together.

Pharmacokinetics Patients with contractions may be initially given subcutaneous terbutaline. Some health care providers may repeat every 1 to 6 hours if the maternal pulse is less than 130 beats/min. Less commonly, health care providers administer continuous intravenous infusions, starting with dosages from 2.5 to 5 mcg/min, which may be increased 2.5 to 5 mcg/min every 20 to 30 minutes with a maximum of 25 mcg/min. Patients are monitored to determine whether and when contractions diminish or cease. Terbutaline is minimally protein-bound (25%) and metabolized via the liver to inactive metabolites. Its half-life is 11 to 16 hours.

Pharmacodynamics Oral terbutaline has an onset of action of 30 to 45 minutes, a peak plasma/serum concentration of 1 to 2 hours, and a duration of action of 4 to 8 hours. IV and subcutaneous terbutaline have an onset of action within 15 minutes, a peak serum concentration level in 30 to 60 minutes, and a duration of action of 1.5 to 4 hours subcutaneously.

Adverse Reactions. Maternal side effects include tremors, malaise, weakness, dyspnea, tachycardia, increased systolic blood pressure, decreased diastolic blood pressure, chest pain, nausea, vomiting, diarrhea, constipation, erythema, sweating, hyperglycemia, and hypokalemia. Many of these effects are associated with terbutaline's cross-reactivity with beta$_1$-adrenergic receptors. More serious adverse reactions include pulmonary edema, dysrhythmias, ketoacidosis, and anaphylactic shock. Fetal side effects include tachycardia and potential hypoglycemia resulting from fetal hyperinsulinemia caused by maternal hyperglycemia. Terbutaline is contraindicated in patients with cardiac disease and those with poorly controlled hyperthyroidism or diabetes mellitus.

Drug Interactions. The increased effects of general anesthetics can produce additive hypotension. Pulmonary edema can occur with concurrent use of corticosteroids. Cardiovascular effects may be additive with other sympathomimetic drugs, such as epinephrine, albuterol,

TABLE 53-5 DRUGS USED TO DECREASE UTERINE CONTRACTILITY

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Beta-Adrenergic Agents		
terbutaline	Follow agency protocol for specific directives plus individual health care provider's order; may be given subQ; usually therapy is 0.25-0.5 mg subQ every 3-4 h	Sympathomimetic beta$_2$-adrenergic agonist. Partially metabolized in liver; excreted by kidneys. May require repeat therapy; 40%-50% rate of tocolytic breakthrough and recurrence of preterm labor 3 wk after start of PO therapy (possibly due to desensitization of beta receptors over time). Monitor MHR. Current research focuses on use of portable low-dose continuous subcutaneous pumps that deliver intermittent bolus doses based on data reflecting peak need periods. Increases in maternal pulse and FHR. Rapidly crosses placenta; breastfeeding not contraindicated because of short half-life Additive effect with CNS depressants (narcotics, sedative-hypnotics) and neuromuscular blocking agents Pregnancy category: B; t½: 11-16 h; Onset: 15 min IV/subQ and 30-45 min PO; Duration: 4-8 h PO and 1.5-4 h subQ; peak serum levels: 0.5-1 h IV/subQ and 1-2 h PO
Calcium Antagonists		
magnesium sulfate	Follow agency protocol for specific directives plus individual health care provider's order for concentration and mL/h IV. Usual LD: 4-6 g in 100 mL over 15-20 min; maint: 40 g in 1 L IVF at 2-4 g/h. Dose based on serum magnesium levels, DTR assessment, and uterine response	Calcium antagonist and CNS depressant. Relaxes uterine smooth muscle through calcium displacement. Must be given by infusion pump for accurate dosing. Freely crosses placenta. Few contraindications allow for use in patients with life-threatening complications. Monitor maternal magnesium levels through serum analyses, DTR, respiratory rate, and urinary output. Elevated levels may be evident in newborn for 7 d; observe newborn for 24-48 h for signs of toxicity if mother treated close to delivery; breastfeeding not contraindicated Antidote: IV: calcium gluconate 1 g over 3 min Pregnancy category: B; Onset: immediate by IV; Duration: 30 min

CNS, Central nervous system; *d,* day; *DTR,* deep tendon reflex; *FHR,* fetal heart rate; *h,* hour; *IV,* intravenous; *IVF,* intravenous fluid; *LD,* loading dose; *maint,* maintenance; *MHR,* maternal heart rate; *min,* minute; *PO,* by mouth; *subQ,* subcutaneously; *t½,* half-life; *wk,* week.

and isoproterenol. Beta-adrenergic blocking agents, such as propranolol HCl (Inderal), nadolol (Corgard), pindolol timolol maleate and metoprolol tartrate (Lopressor), antagonize beta-sympathomimetics.

Magnesium Sulfate

Magnesium sulfate, a calcium antagonist and central nervous system depressant, relaxes the smooth muscle of the uterus through calcium displacement and is more commonly given as a tocolytic. Administered IV, the drug has a direct depressant effect on uterine muscle contractility. It increases uterine perfusion, which has a therapeutic effect on the fetus. It is also less expensive and may be safer to use than the beta-sympathomimetics because it has fewer adverse effects. It can also be used when beta-sympathomimetics are contraindicated (e.g., in patients with diabetes and cardiovascular disease). The drug is excreted by the kidneys and crosses the placenta. Magnesium sulfate is administered as a 4 to 6 intravenous load over 20 minutes followed by a continuous infusion over 20 minutes of 2 to 4 g/h. The maintenance dose must be titrated to keep uterine contractions under control, and magnesium levels are drawn based on clinical response of the patient. Magnesium sulfate therapy is contraindicated in patients who have myasthenia gravis; impaired kidney function and recent myocardial infarction are relative contraindications. Patients with renal impairment may require adjusted dosages.

Adverse Reactions. Dosage-related side effects in the patient include flushing, feelings of increased warmth, perspiration, dizziness, nausea, headache, lethargy, slurred speech, sluggishness, nasal congestion, heavy eyelids, blurred vision, decreased GI action, increased pulse rate, and hypotension. Increased severity is evidenced by depressed reflexes, confusion, and magnesium toxicity (respiratory depression and arrest, circulatory collapse, cardiac arrest). Side effects in the fetus are decreased fetal heart rate (FHR) variability, and in the neonate are respiratory depression, slight hypotonia with diminished reflexes, and lethargy for 24 to 48 hours. If maternal neurologic, respiratory, or cardiac depression is evidenced, the antidote is calcium gluconate (1 g IV push over 3 minutes).

Nursing Interventions during Tocolytic Therapy

- Monitor vital signs, FHR, fetal activity, and uterine activity as ordered. Report respirations fewer than 12 per minute, which may indicate magnesium sulfate toxicity.

- Monitor intake and output (I&O). Report urinary output <30 mL/hr.
- Assess breath and bowel sounds as ordered, or at least every 4 hours.
- Assess deep tendon reflexes (DTRs) and clonus before initiation of therapy and as ordered. Notify health care provider of changes in DTRs (areflexia or hyporeflexia) and clonus.
- Assess pain and uterine contractions
- Weigh daily at the same time.
- Monitor serum magnesium levels as ordered (therapeutic level is 4 to 7 mg/dL).
- Have calcium gluconate (1 g given IV over 3 minutes) available as an antidote.
- Observe newborn for 24 to 48 hours for magnesium effects if drug was given to mother before delivery.

Nursing Process
Patient-Centered Collaborative Care

Beta$_2$-Adrenergic Agonists: Terbutaline

Assessment
- Identify risks for PTL early in pregnancy.
- When a patient has preterm uterine contractions, obtain a history, complete physical assessment, vital signs, FHR, and urine specimen for screening for intrauterine infection and urinary tract infection.

Nursing Diagnoses
- Anxiety related to potential for early labor and birth and pregnancy loss.
- Deficient knowledge related to etiology and nonpharmacologic and pharmacologic interventions for PTL
- Ineffective self-health management related to nonpharmacologic and pharmacologic interventions for PTL and long-term implications for patient and fetus or infant
- Risk for activity intolerance related to nonpharmacologic and pharmacologic interventions for PTL

Planning
- Patient's preterm uterine contractions will cease by resting in left side-lying position, increasing fluid intake, assuming pelvic rest, and following tocolytic therapy as directed.
- Patient has no progressive cervical change.

Nursing Interventions
- Monitor and assess uterine activity and FHR.
- Maintain patient in left lateral position as much as possible to facilitate uteroplacental perfusion.
- Monitor vital signs per unit protocol, specifically maternal pulse. Report maternal heart rate greater than 130 beats/min.
- Report auscultated cardiac dysrhythmias. An electrocardiogram (ECG) may be ordered.
- Auscultate breath sounds (anteriorly, posteriorly, and bilaterally) every 4 hours. Notify health care provider if respirations are more than 30 per minute or if quality changes (wheezes, rales, coughing).
- Monitor daily weight (at the same time of day) to assess fluid overload; implement strict I&O measurement.
- Report baseline FHR over 180 beats/min or any significant increase in uterine contractions from pretreatment baseline.
- Report persistence of uterine contractions despite tocolytic therapy.
- Report leaking of amniotic fluid, any vaginal bleeding or discharge, or complaints of rectal pressure.
- Be alert to presence of maternal hyperglycemia and hypokalemia and hypoglycemia in the newborn delivered within 5 hours of discontinued beta-sympathomimetic drugs.

Patient Teaching
General
- Advise patient of signs and symptoms of PTL (menstrual-type cramps, sensation of pelvic pressure, low backache, increased vaginal discharge, abdominal discomfort).
- Advise patient that if she experiences PTL contractions, initial action should be to void, recline on her left side to increase uterine blood flow, and drink extra fluids. Emphasize that she should notify her health care provider if uterine contractions do not cease or if they increase in frequency.
- Explain side effects of beta-sympathomimetic drugs. Report heart palpitations or dizziness to health care provider.
- Advise patient to contact health care provider before taking any other drugs while on tocolytic drug therapy.

Cultural Considerations
- Provide an interpreter with same ethnic background and gender as patient if possible, especially when dealing with sensitive topics or stressful situations.

Evaluation
- Evaluate effectiveness of tocolytic drug by noting six or fewer uterine contractions in 1 hour or per health care provider order.
- Evaluate patient's understanding of nonpharmacologic measures for decreasing preterm contractions: bed rest, increasing oral fluid intake, pelvic rest, and lying on her left side.
- Continue monitoring patient's vital signs, FHR, and uterine activity. Report any change immediately.

CORTICOSTEROID THERAPY IN PRETERM LABOR

The desired outcome of tocolytic therapy is prevention or cessation of PTL. Patients at risk for preterm delivery (24 to 34 weeks' gestation) should receive antenatal corticosteroid therapy with betamethasone (Celestone) or dexamethasone. An off-label use, administration of antenatal corticosteroids accelerates lung maturation and lung surfactant development in the fetus in utero, decreasing the incidence and severity of respiratory distress syndrome (RDS) and increasing survival of preterm infants. Antenatal therapy decreases infant mortality, RDS, and intraventricular bleeds in neonates born between 24 and 34 gestational weeks. The effects and benefits of corticosteroid administration are believed to begin 24 hours after administration and last for up to 1 week. The goal is to delay delivery by 48 hours to maximize the effect of the glucocorticoids. Research by the Agency for Healthcare Research and Quality has found that approximately one fifth of patients do not receive the recommended corticosteroids before delivery of premature births.

Surfactant is made up of two major phospholipids: sphingomyelin and lecithin. Sphingomyelin initially develops in greater quantity (from about the 24th week) than lecithin. However, by the 33rd to 35th weeks of gestation, lecithin production peaks, making the ratio of the two substances about 2:1 in favor of lecithin. This is called the **L/S (lecithin/sphingomyelin) ratio**, measured in the amniotic fluid. The L/S ratio is a predictor of fetal lung maturity and risk for neonatal RDS.

Patients with gestational hypertension, PROM, placental insufficiency, some types of diabetes, or narcotic abuse may have amniotic fluid with higher than expected L/S ratios for the gestational date because of a stress-induced increase in endogenous corticosteroid production.

Betamethasone

When PTL occurs before the 32nd week of gestation, corticosteroid therapy with betamethasone may be prescribed. The usual dose is 12 mg intramuscularly (IM) every 24 hours for 2 doses.

Adverse Reactions

Side effects of betamethasone are rare but include seizures, headache, vertigo, edema, hypertension, increased sweating, petechiae, ecchymoses, and facial erythema.

Dexamethasone

In clinical controlled trials, evidence is insufficient to recommend betamethasone over dexamethasone, because the two have not been directly compared. Investigations have noted a trend of decreased risk of neonatal cystic periventricular leukomalacia and intraventricular hemorrhage with exposure to betamethasone over dexamethasone. Dexamethasone has a rapid onset of action and a shorter duration of action; therefore, it must be prescribed in a shorter frequency compared with betamethasone. The recommended antepartum regimen for dexamethasone is 6 mg IM every 12 hours for 4 doses.

SAFETY: Preventing Medication Errors

Do not confuse…

- **Dexamethasone,** a corticosteroid used to accelerate fetal lung maturity during weeks 24 to 34 of gestation, with **desoximetasone** (Topicort), which is used to treat inflammation from corticosteroid responsive dermatoses.

Adverse Reactions

The potential adverse reactions associated with dexamethasone therapy include insomnia, nervousness, increased appetite, headache, hypersensitivity reactions, and arthralgias. Table 53-6 lists the prenatal drugs used for surfactant development and their dosages, uses, and considerations.

TABLE 53-6 PRENATAL THERAPY FOR SURFACTANT DEVELOPMENT

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
betamethasone (Celestone)	IM: 12 mg IM	Corticosteroid. Given to prevent RDS in preterm infants by injecting mother before delivery to stimulate surfactant production in fetal lung. Not effective in treating preterm infant after delivery. Most effective if given at least 24 h (preferably 48-72 h) but less than 7 d before delivery in week 33 or before. Contraindicated in severe gestational hypertension and in systemic fungal infection. Simultaneous use with terbutaline may enhance risk for pulmonary edema. May mask signs of chorioamnionitis, so not usually given with ruptured membranes. Metabolized in liver and excreted by kidneys; crosses placenta; enters breast milk. Therapy less effective with multifetal birth and with male infants. Pregnancy category: C; PB: 64%; t½ : 6.5 h; Onset: 1-3 h; Peak: IV: 10-36 min; Duration: 7-14 d
dexamethasone	IM: 6 mg q12h × 4 doses	Same as betamethasone but shorter half-life and more significant variation in circulating serum levels

d, Day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *min,* minute; *PB,* protein-binding; *RDS,* respiratory distress syndrome; *t½,* half-life.

Nursing Process
Patient-Centered Collaborative Care

Betamethasone (Celestone)

Assessment
- Assess for history of hypersensitivity.
- Assess vital signs; report abnormal findings.
- Assess FHR.

Nursing Diagnoses
- Anxiety related to potential for preterm labor and birth with uncertain fetal outcome secondary to fetal immaturity
- Deficient knowledge related to use of antenatal corticosteroids for promotion of fetal lung maturity in preterm delivery.

Planning
- Patient will not deliver within 24 hours of receiving betamethasone.

Nursing Interventions
- Shake the suspension well. Avoid exposing to excessive heat or light.
- Inject into large muscle (not deltoid) to avoid local atrophy.
- Monitor maternal vital signs.
- Maintain accurate I&O.
- Check blood glucose if used for patient with diabetes mellitus.

Cultural Considerations
- Provide an interpreter with same ethnic background and gender as patient if possible, especially when dealing with sensitive topics or stressful situations.

Evaluation
- Continue monitoring patient's vital signs. Report changes.
- Continue monitoring FHR. Report changes.
- Monitor neonate for hypoglycemia and presence of neonatal sepsis.

DRUGS FOR GESTATIONAL HYPERTENSION

Gestational hypertension (elevated blood pressure without proteinuria after 20 gestational weeks in patients normotensive before pregnancy), the most common serious complication of pregnancy, can have devastating maternal and fetal effects. Gestational hypertension has replaced the term *pregnancy-induced hypertension,* still commonly used in clinical discussions but no longer correct. With proper management of gestational hypertension, the prognosis for both patient and infant is good. Hypertensive disorders are reported in 10% to 20% of all pregnant patients, with 5% to 8% of all pregnancies reflecting incidence of **preeclampsia** (gestational hypertension with proteinuria). The condition is most often observed after 20 weeks gestation, intrapartum, and during the first 72 hours postpartum, though late postpartum preeclampsia-eclampsia may present more than 48 hours but less than 4 weeks postpartum.

BOX 53-1 PREDISPOSING FACTORS IN PREECLAMPSIA

- African American
- Primigravida (first pregnancy)
- History of preeclampsia
- Younger than 20 years or older than 35 years (especially primigravida)
- Multifetal gestation
- Family history of preeclampsia
- Gestational trophoblastic disease
- Pregestational diabetes mellitus
- Preexisting hypertensive, vascular, or renal disease
- Antiphospholipid antibody syndrome

The cause of preeclampsia remains unknown, although numerous hypotheses exist. The pathophysiology of preeclampsia and **eclampsia** (new-onset grand mal seizures in a patient with preeclampsia) is believed to be related to decreased levels of vasodilating prostaglandins with resulting vasospasm. The major predisposing risk factors for the development of preeclampsia are listed in Box 53-1.

The two categories of gestational hypertension—preeclampsia and eclampsia—are based on clinical manifestations. Preeclampsia is the presence of hypertension (systolic blood pressure >140 mm Hg or diastolic blood pressure >90 mm Hg) and proteinuria (≥300 mg in 24-hour urine collection) in a normotensive pregnant patient after 20 weeks' gestation. Preeclampsia is subdivided into *mild* preeclampsia and *severe* preeclampsia (Table 53-7).

About 5% of preeclamptic patients, notably those without adequate prenatal care, progress to eclampsia, in which seizure activity occurs and maternal mortality rate is about 10% to 15% in low- and middle-income countries. Early diagnosis of preeclampsia with appropriate treatment keeps most preeclamptic patients from progressing to this stage. Approximately 13% to 16% of eclampsia occurs postpartum.

A severe sequela of preeclampsia is known as **HELLP syndrome** (defined by *H*emolysis, *E*levated *L*iver enzymes, and *L*ow *P*latelet count), which occurs in about 2% to 12% of patients with gestational hypertension. Patients who manifest severe preeclampsia are most likely to also have HELLP syndrome.

Two primary treatment goals in preeclampsia, in addition to delivery of an uncompromised fetus and psychological support for the patient and family, are reduction of vasospasm and prevention of seizures.

Delivery of the infant and placenta (products of conception) is the only known cure for preeclampsia. Vaginal

TABLE 53-7 **COMPARISON OF MILD AND SEVERE PREECLAMPSIA AND ECLAMPSIA**

MILD PREECLAMPSIA	SEVERE PREECLAMPSIA	ECLAMPSIA
Blood pressure increase to >140 and/or >90 diastolic but <160 systolic	Blood pressure increase of >160/110 on two occasions at least 6 h apart (patient on bed rest)	Signs and symptoms of mild or severe preeclampsia and one grand mal seizure
Proteinuria >300 mg in 24 h or +1 ± 2 on dipstick; edema not generalized; noted in hands, feet	Proteinuria >5 g in 24 h or 3+ or greater in two random samples 4 hours apart; edema generalized; found in face (periorbital, coarse features), hands, lower extremities (ankles), abdomen, and dependent areas	
Weight gain >1 lb/wk before 32 wk or >2.5 lb/wk after 34 wk	Weight gain up to 10 lb in 1 wk	
Deep tendon reflexes in arms and legs only slightly increased (0: no response; 1+: sluggish/low; 2+: normal active; 3+: brisk)	Deep tendon reflexes in arms and legs hyperactive (4+: hyperactive/transient clonus; 5+: brisk; clonus sustained)	
Adequate urinary output (1 mL/kg/h)	Oliguria present (<400 mL per 24 h)	
No major cerebral or visual symptoms	Cerebral or visual symptoms, particularly blurred vision, spots, flashing lights, and/or persistent and severe headache in frontal area	
May have mild frontal headache	Severe headache	
No epigastric pain	Epigastric pain may be present; pulmonary edema, cyanosis	

h, Hour; *wk,* week; *>,* greater than; *<,* less than.

delivery is preferred so that anesthesia or surgical risks will not be added. Labor induction via cervical ripening may be initiated to facilitate labor. For a vaginal delivery, epidural anesthesia or combined epidural and spinal anesthesia is frequently performed for pain management while promoting uteroplacental circulation. Maternal hypotension is a significant concern for hypertensive patients who have epidurals. In contrast, parturients with worsening preeclampsia or fetal distress may be delivered via cesarean section. Patients with HELLP syndrome may have their labor induced for a vaginal delivery at 32 or more weeks' gestation. For patients with HELLP syndrome who are at less than 32 weeks' gestation, cesarean delivery may be considered.

If a patient's disease progresses to the point of eclampsia (maternal seizure), delivery is generally postponed for 1 to 3 hours if fetal status allows. The labor induction or cesarean delivery is an additional stressor for the patient who exhibits acidosis and hypoxia resulting from seizure. Ideally, once vital signs are stabilized with improved urinary output and decreased acidosis/hypoxia, delivery is pursued.

Nonpharmacologic treatments for preeclampsia include activity reduction, lying on the left side, increased dietary protein (supplemental 90 g/day), psychosocial therapy, and biofeedback, but the aforementioned recommendations have been studied and shown not to have clinically beneficial effects. Therefore, drug therapy is commonly used for treatment.

Methydopa, Hydralazine, and Magnesium Sulfate

Methyldopa , hydralazine , and Labetalol (Trandate) are considered first-line therapy for preeclampsia, because they have been most widely used in pregnant patients and their safety and efficacy have been established. Additional alternatives include the beta blocker prazosin (Minipress), the calcium channel blocker nifedipine (Procardia), and the centrally acting alpha agonist clonidine (Catapres). Beta blockers are generally considered safe, but there is potential for impaired fetal growth if used early in pregnancy. Nifedipine has been used with no major problems. Patients should avoid diuretics because of the potential alteration in plasma volume. Patients in the second and third trimesters should avoid taking angiotensin-converting enzyme inhibitors because of the potential for fetal renal toxicity. Table 53-8 lists the two most commonly used drugs for treating preeclampsia, magnesium sulfate and hydralazine, and their dosages, uses, and considerations.

Adverse Reactions of Methyldopa

Observe the patient for peripheral edema, anxiety, nightmares, drowsiness, headache, dry mouth, drug fever, and mental depression. These are the most common potential adverse reactions.

Adverse Reactions of Hydralazine

Observe the patient for headache, nausea, vomiting, nasal congestion, dizziness, tachycardia, palpitations, and angina pectoris. Avoid a sudden decrease in maternal blood pressure, which may cause fetal hypoxia. Hydralazine has no known direct adverse effects on the fetus.

Adverse Reactions of Magnesium Sulfate

Early signs of increased magnesium levels include lethargy, flushing, feelings of increased warmth, perspiration, thirst, sedation, heavy eyelids, slurred speech, hypotension, DTR,

TABLE 53-8 DRUGS USED IN SEVERE PREECLAMPSIA

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
magnesium sulfate	LD: IV: 6 g in 20 min; piggyback via infusion pump; maint: 2-3 g/h IV via infusion pump	Prevention and treatment of seizures related to preeclampsia. Acts as CNS depressant. Decreases acetylcholine from motor nerves, which blocks neuromuscular transmission and decreases incidence of seizures. Secondary effect is reduction in blood pressure as magnesium sulfate relaxes smooth muscle. Secondarily affects peripheral vascular system with increased uterine blood flow caused by vasodilation and some transient BP decrease during first hour; also inhibits uterine contractions. Depresses DTRs and respiration; maintenance dose depends on reflexes, respiratory rate, urinary output, and magnesium level. Main risk is production of abnormally high serum magnesium levels. Therapeutic levels range from 4-7 mEq/L; effective in preventing seizures. Patient at risk if respiratory rate <12/min, urinary output <30 mL/h, DTR absent or hyporeflexic. Patellar reflexes disappear with serum magnesium levels of 8-10 mEq/L. Maternal respiratory depression may occur with levels >10-15 mEq/; cardiac arrest with levels >20-25 mEq/L. Notify health care provider of any of the above occurs Can be given IV or IM (infrequent). Do not give parenterally to patients with heart block or myocardial damage. Use with caution in patients with renal impairment. Absorbed magnesium is excreted by kidneys; excreted in breast milk, but breastfeeding not contraindicated. Contraindicated in patients with myasthenia gravis. Relative contraindications: myocardial damage or heart block Antidote: IV: calcium gluconate 1 g slow IV push over 3 min Pregnancy category: B; PB: UK; t½: UK; Onset: IV immediate, IM 1 h; Duration: IV 30 min, IM 3-4 h; infusion usually stopped 24 h postpartum
hydralazine hydrochloride	IV: IV push: 5-10 mg doses every 20 min; *max cumulative total:* 20 mg or until blood pressure controlled IM and PO routes not usually used	Antihypertensive agent. Causes arteriolar vasodilation. Usually lowers diastolic BP more than systolic BP. Objective is to maintain diastolic BP of 90-110 mm Hg. Usually not given to pregnant preeclamptic patients with diastolic BP >105 mm Hg because of risk for reduced intervillous blood flow. Patients with impaired renal function may require lower doses Parenteral: Onset: 5-20 min; Peak: 10-80 min; Duration: 2-6 h; well tolerated; maternal tachycardia and increased cardiac output and oxygen consumption may occur. Oral: Onset: 20-30 min; Peak: 1-2 h; Duration: 2-4 h
methyldopa (🍁 Apo-Methyldopa)	IV: 250-500 mg every 6-8 h, *max:* 1 g every 6 h PO: 250 mg b.i.d., *max:* 3 g/d	Stimulates central alpha-adrenergic receptors, resulting in decreased sympathetic outflow to heart, kidneys, and peripheral vasculature. Contraindicated in patients with hypersensitivity to drug or any component. Active hepatic disease, liver disorders previously associated with use of methyldopa, concurrent use with MAOIs Caution: Sedation is usually transient during initial treatment and dosage increases
labetalol (Trandate)	IV: 20 mg, followed by 40 mg, then 80 mg, and then 80 mg every 10 min until blood pressure controlled or max cumulative dose of 220 mg given	Pregnancy category: C; t½: 75-80 min; Onset 3-6 h; Duration 12-24 h

b.i.d., Two times a day; *BP,* blood pressure; *CNS,* central nervous system; *d,* day; *DTR,* deep tendon reflex; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *LD,* loading dose; *maint,* maintenance; *MAOIs,* monoamine oxidase inhibitors; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; >, greater than; <, less than, 🍁, Canadian drug.

and decreased muscle tone. Adverse reactions generally occur with serum magnesium sulfate levels greater than 10 mEq/L. Therapeutic levels are 4 to 7 mEq/L. Loss of patellar reflexes is often the first sign of magnesium toxicity and may be seen at 8 to 10 mEq/L. Respiratory depression may manifest at levels greater than 10 to 15 mEq/L, and cardiac arrest may manifest at levels greater than 20 to 25 mEq/L.

Decreased variability is commonly seen on the FHR tracing. If the patient received magnesium sulfate close to the time of delivery, the neonate may exhibit low Apgar scores, hypotonia, lethargy, weakness, and potential respiratory distress. The fetal level of magnesium generally reaches more than 90% of maternal levels within 3 hours of administration. There is no evidence linking congenital defects and maternal hypocalcemia or hypermagnesemia. The greater risk to the fetus is from maternal preeclampsia with resulting decreased placental blood flow and intrauterine growth retardation.

Nursing Process
Patient-Centered Collaborative Care

Gestational Hypertension

Assessment
- Review baseline vital signs from early pregnancy and BP readings during prenatal visits.
- Identify patient history that may predispose patient to preeclampsia.

Nursing Diagnoses
- Deficient knowledge related to preeclampsia, diagnosis, treatment modalities, and common outcomes for patient and infant
- Ineffective renal perfusion and perfusion of cerebral and peripheral tissue; risk to fetal well-being secondary to vasospasm
- Anxiety related to possible preterm hospitalization and delivery with possible adverse fetal or maternal outcomes
- Risk for injury related to maternal seizure activity and magnesium toxicity
- Deficient fluid volume related to shift of intravascular fluid to extravascular space as outcome of vasospasm with subsequent elevated arterial hypertension

Planning
- Patient's BP will be maintained within acceptable ranges.
- Patient will verbalize understanding of preeclampsia, etiology, signs and symptoms, and nonpharmacologic and pharmacologic treatment measures.
- Patient will understand and comply with planned preeclampsia treatment regimen.
- Fetus will tolerate impaired uteroplacental perfusion and subsequent delivery without injury.
- Therapeutic magnesium levels will be maintained.
- Magnesium sulfate infusion will be planned for at least 24 hours postpartum.

Patient Teaching
General
- Explain to patient preeclampsia and its implications for patient, fetus, and newborn.
- Provide patient with information about nonpharmacologic and pharmacologic treatment measures for preeclampsia.
- Advise patient to avoid exposure to infection.
- Remind patient with diabetes to check her glucose level as ordered.

Side Effects
- Advise patient to report immediately any breathing difficulty, weakness, or dizziness.
- Advise patient to report changes in stool, easy bruising, bleeding, blurred vision, unusual weight gain, and emotional changes.

Safety
- Advise patient to lie in left lateral recumbent position, and explain rationale.
- Educate patient on signs and symptoms of progressive preeclampsia and when to seek medical assistance.
- Explain to patient that fetal well-being will be assessed through biophysical profile (BPP), nonstress test (NST), or contraction stress test at frequent intervals, depending on health care provider and preeclampsia severity (e.g., NST and/or BPP 1 to 2 times per week).
- Educate family regarding possibility of seizures and appropriate actions if seizure occurs.

Diet
- Provide nutritional counseling on need for additional protein intake (90 g) to make up for urinary protein losses; normal sodium diet; and importance of adequate fluid intake.
- Explain to patient the rationale for daily weights.

Magnesium Sulfate
- Explain to patient why she will have an indwelling catheter, infusion pump, continuous fetal monitoring, and assessment of DTRs and clonus. Explain that therapy will extend into postpartum period 24 to 48 hours, depending on agency and health care provider.
- Explain to patient about visitor restrictions and need for low-stimulation environment.
- Advise patient that she will likely experience flush, warm sensation, and possibly nausea and vomiting during initial loading dose.
- Advise patient that evidence of magnesium levels within therapeutic range includes decreased appetite, some speech slurring, double vision, and weakness.

Hydralazine

- Explain to patient that nurses will be monitoring pulse and BP almost constantly until they become stable after administration, then every 15 minutes thereafter. Explain that an electronic BP monitor may be used to obtain constant readings. Some health care providers will request manual BP measurements.
- Explain to patient the need for careful measuring of I&O.
- Inform patient she may experience headache as a side effect of the drug.

Nursing Interventions

Magnesium Sulfate

- Provide continuous electronic fetal monitoring.
- Monitor for maternal toxicity. Lethargy and weakness result from blocking of neuromuscular transmission. Diaphoresis, flushing, feelings of warmth, and nasal congestion are results of vasodilation from relaxation of smooth muscle.
- Have airway suction, resuscitation equipment, and emergency drugs available.
- Have antidote available. Calcium gluconate (1 g) IV is given over 3 minutes.
- Maintain patient in left lateral recumbent position in low-stimulation environment. Provide close observation.
- For IM administration, use Z-track technique and rotate sites (drug is painful and irritating). Rarely is magnesium sulfate administered IM.
- Monitor BP, pulse, and respiratory rate per agency protocol; monitor DTRs, clonus, and I&O (with urimeter) every hour. Some health care providers will request manual BP measurements.
- Monitor temperature, breath sounds, and bowel sounds every 4 hours.
- Check urine for protein every hour.
- Assess for epigastric pain, headache, visual symptoms (blurred vision and scotoma), sensory changes, edema, level of consciousness, and seizure activity on ongoing basis.
- Monitor serum magnesium levels according to agency protocol for range between 4 to 7 mEq/L.
- Notify health care provider if you observe: decreased or changed level of consciousness; respirations <12/min; absence of DTR; urinary output <30 mL/h; systolic BP ≥160 mm Hg, unless ordered otherwise; magnesium level >7 mEq/L; absent bowel sounds or altered breath sounds; epigastric pain or right upper quadrant pain (associated with hepatic edema causing stretching of the liver capsule); headache; visual symptoms (blurred vision and scotoma); sensory changes; change in affect or level of consciousness, seizure activity.
- Monitor laboratory reports for low platelet count, elevated liver enzymes (AST, LDH), and bilirubin levels. Observe for evidence of excessive bleeding.
- Monitor fetal status. FHR baseline should remain at 110 to 160 beats/min.
- Monitor 24-hour urinary protein laboratory results if ordered (≥300 mg/day is abnormal).
- Monitor patient for magnesium toxicity.
- Monitor newborn for effects of placental exposure to excess magnesium sulfate. Although infrequent, newborn side effects include lethargy, neurologic or respiratory depression, and muscle hypotonia.

Hydralazine

- Take pulse and BP every 5 minutes when drug is administered, or monitor with electronic BP device until stabilized, then every 15 minutes. Some health care providers will request manual BP measurements.
- Observe for maintenance of diastolic BP between 90 and 110 mm Hg or as ordered.
- Observe for change in level of consciousness and headache.
- Monitor I&O to avoid hypotensive episodes or overload.
- Monitor FHR.

Cultural Considerations

- Provide an interpreter with same ethnic background and gender as patient if possible, especially when dealing with sensitive topics or stressful situations.

Evaluation

- Evaluate effectiveness of therapy to reduce BP.
- Continue monitoring vital signs. Report changes.
- Document effect of teaching and learning opportunities on patient's knowledge deficit about preeclampsia treatment modalities and outcomes.
- Note fetal well-being secondary to treatment with drugs as evidenced by fetal monitoring and fetal movement assessment.
- Monitor maternal physiologic changes in relation to magnesium sulfate levels.
- Continue monitoring FHR. Report changes.

CRITICAL THINKING CASE STUDY

TA (gravida 3, para 0) has a history of spontaneous abortion at 10 weeks' gestation and a preterm delivery and demise of a neonate at 21 weeks' gestation. At her 28-week prenatal visit, she reports increased clear vaginal discharge and feelings of pelvic pressure. Examination of her cervix reveals 2-cm dilation and a presenting fetal part low in the pelvis. TA is admitted to the hospital, and uterine activity is documented. Magnesium sulfate therapy is ordered for treatment of preterm labor. The nurse prepares for magnesium sulfate administration by the intravenous route.

1. How will magnesium sulfate therapy be initiated? What intervals and dosages should be anticipated?
2. What maternal and fetal side effects will the nurse expect to observe?
3. What should TA be told about the drug effects she will experience?
4. How would the nurse respond to TA's questions about the risks of preterm delivery?

   After 24 hours of magnesium sulfate therapy, uterine contractions have been reduced to two to three per hour. TA is to be discharged home. The nurse is preparing TA's discharge teaching.
5. What instructions should the nurse give TA about her activity and diet?
6. TA asks whether the side effects of magnesium sulfate will continue. What is an appropriate nursing response?
7. What signs and symptoms should TA be advised to report?

NCLEX STUDY QUESTIONS

1. A patient at 33 weeks' gestation is diagnosed with preterm labor. The nurse prepares to administer betamethasone 12 mg. The nurse knows that this patient understands the patient education when she states, "This medication will help my baby's lungs mature…" and what else?
   - a. "and is effective within 24 hours and up to 1 week."
   - b. "if I remain in bed for the next 6 weeks on my side."
   - c. "if I take my medicine at the same time every day."
   - d. "if I avoid sexual intercourse for the remainder of my pregnancy."
2. The nurse notes that a prenatal patient is Rh negative, has hemoglobin 9.7 g/dL, positive HIV test, positive rubella titer, and positive PPD. Based on these results, after the patient's aminocentesis, the nurse prepares to administer what?
   - a. RhO(D) immune globulin
   - b. Measles-mumps-rubella vaccine
   - c. hepatitis B (Engerix-B, Recombivax HB) vaccine
   - d. isoniazid (INH)
3. The nurse is teaching a prenatal patient how to decrease the gastrointestinal distress she experiences with prenatal vitamins. The nurse instructs the patient to do what?
   - a. "Take the vitamins between meals."
   - b. "Eat when you take your vitamins."
   - c. "Drink orange juice when you take your vitamins."
   - d. "Drink milk when you take your vitamins."
4. The nurse at an infertility clinic is working with a preconceptual couple. The nurse advises the woman to take which supplement for at least 3 months before becoming pregnant?
   - a. Iron
   - b. Ginger
   - c. Folic acid
   - d. Vitamin B_6
5. The nurse at a prenatal clinic is reviewing messages to be returned to patients that afternoon. Which patient will the nurse call first?
   - a. Primigravida, 10 gestational weeks, with nausea and vomiting, who requests information about ginger
   - b. Gravida 2, 35 gestational weeks, with Braxton Hicks contractions, who requests information about caffeine
   - c. Gravida 2, 32 gestational weeks, who has gestational diabetes with a blood sugar of 132 and requests information about her insulin
   - d. Primigravida, 28 gestational weeks, with preeclampsia, who requests information about taking Motrin for headache
6. A patient with severe preeclampsia is on magnesium sulfate. The laboratory report shows a magnesium sulfate level of 7 mEq/L. Which is the most appropriate initial nursing intervention?
   - a. Continue to monitor the patient because this level is therapeutic.
   - b. Contact the health care provider, and report the level.
   - c. Prepare to administer 1 g of calcium gluconate.
   - d. Turn the patient on her left side, and administer 10 L of oxygen by nasal cannula.
7. The nurse is assessing a patient in preterm labor who is receiving magnesium sulfate. What is the finding of most concern?
   - a. Lethargy
   - b. Feelings of warmth
   - c. Loss of patellar reflexes
   - d. Positive clonus +2 bilaterally
8. The patient has been receiving magnesium sulfate IV for 24 hours to treat severe preeclampsia. On assessment, the nurse finds the following: temperature 37.3° C (99° F), pulse 88, respirations 14, BP 138/76, 21 patellar reflexes, and negative ankle clonus. What is the priority nursing intervention?
   - a. Obtain a stat magnesium sulfate level.
   - b. Discontinue magnesium sulfate.
   - c. Contact the health care provider.
   - d. Continue to monitor.

9. A primigravida patient, 8 gestational weeks, is at the prenatal clinic for her first examination. She complains of nausea and vomiting "every morning." Which comment made by the patient would indicate the need for further instruction?
- **a.** "My friend gave me ginger cookies to eat."
- **b.** "I have been eating dry crackers before I get up."
- **c.** "I have tried to avoid foods with strong smells."
- **d.** "I have been drinking chamomile tea every day."

10. The nurse in labor and delivery is reviewing messages to be returned to patients. Which patient should the nurse call first?
- **a.** "I'm 32 weeks pregnant and taking TUMS for my heartburn. Is there anything else I can take?"
- **b.** "I'm 38 weeks pregnant and taking Motrin for my backache. Should I take aspirin too?"
- **c.** "I'm 8 weeks pregnant and taking folic acid. Will it hurt me or the baby if I stop?"
- **d.** "I checked my blood sugar with a friend's machine and it was 120 mg. I'm not diabetic. Is that normal?"

11. A young adolescent, gravida 1, para 0, is admitted to labor and delivery with preterm labor at 29 weeks' gestation. Which nursing interventions should the nurse include? (Select all that apply.)
- **a.** Administration of antenatal glucocorticoid
- **b.** Liver function tests
- **c.** Bed rest in the left lateral position
- **d.** Administration of bolus IV fluids
- **e.** Administration of tocolytics
- **f.** Administration of an antihypertensive

12. A patient is planning to become pregnant. Which actions should the nurse counsel the patient to initiate before she stops taking her oral contraceptive? (Select all that apply.)
- **a.** Stop smoking.
- **b.** Take omega-6 fatty acid every day.
- **c.** Take a multivitamin every day.
- **d.** Stop taking over-the-counter acetaminophen.
- **e.** See her health care provider.

OBJECTIVES

- Critique systemic and regional medications for pain control during labor, their action, side effects, and nursing implications.
- Describe the nursing process, including patient teaching, associated with the drugs used during labor and delivery.
- Compare drugs used to enhance uterine contractility during labor and after placental expulsion, their action, side effects, and nursing implications.
- Describe the nursing process associated with the administration of surfactant therapy for preterm neonates.

OUTLINE

Drugs for Pain Control during Labor
  Analgesia/Sedation
  Nursing Process: Patient-Centered Collaborative Care: Pain-Control Drugs
  Anesthesia
  Nursing Process: Regional Anesthetics

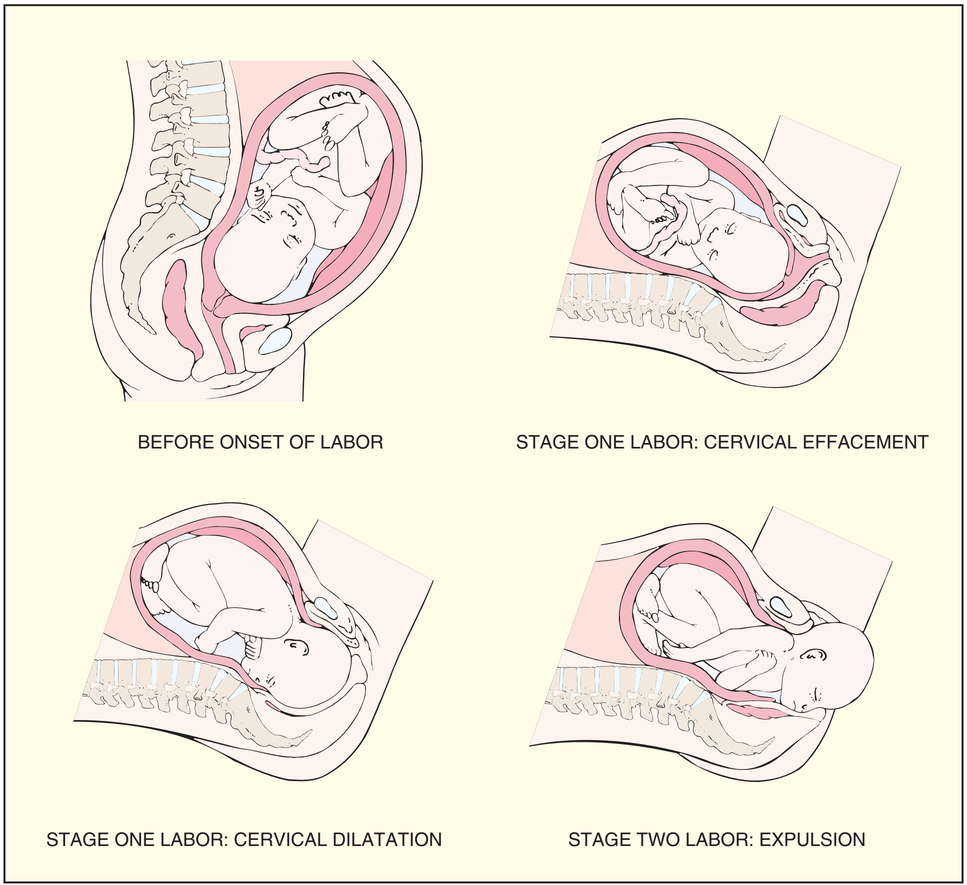
DRUGS FOR PAIN CONTROL DURING LABOR

Labor and delivery are divided into four stages, the first three specific to labor and delivery. During the first stage, the dilating stage, cervical effacement and dilation occur; the cervix thins and becomes fully dilated at 10 cm. The first stage consists of three phases categorized by cervical dilation: the latent phase (0 to 4 cm), the active phase (4 to 7 cm), and the transition phase (8 to 10 cm). The second stage of labor, the pelvic stage, begins with complete cervical dilation and ends with delivery of the newborn (Figure 54-1). During the third stage of labor, the placenta separates from the uterine wall and is delivered. The fourth stage of labor, or the first 1 to 4 hours postpartum, is a period of physiologic stabilization for the mother and initiation of familial attachment.

During the first stage of labor, uterine contractions produce progressive cervical effacement and dilation. As the first stage of labor progresses, uterine contractions become stronger, longer, and more frequent, and discomfort increases. Pain and discomfort in labor are caused by uterine contraction, cervical dilation and effacement, hypoxia of the contracting myometrium, and perineal pressure from the presenting part. Pain perception is influenced by physiologic, psychological, social, and cultural factors, in particular, the woman's past experience with pain, anticipation of pain, fear and anxiety, knowledge deficit of the labor and delivery process, and involvement of support persons.

Before administering pharmacologic treatment, nonpharmacologic measures should be initiated. Nonpharmacologic measures for pain relief during labor include (1) ambulation, (2) supportive positioning of the gravid uterus and promotion of uterine perfusion, (3) touch and massage, (4) hygiene and comfort measures, (5) support persons, (6) breathing and relaxation techniques, (7) transcutaneous electrical nerve stimulation, (8) hypnosis, (9) acupuncture, and (10) hydrotherapy (warm-water baths or showers).

Other nonpharmacologic measures include alternative and complementary medicine. Of particular concern is the use of herbal supplements by the pregnant patient later in pregnancy to stimulate labor. For example, some women ingest pregnancy toner tea, which includes raspberry, nettles, dandelion, alfalfa, and peppermint leaf. Other herbal supplements used include blue cohosh, castor oil, and evening primrose oil. Pregnant patients may self-administer, or the practice may be part of their traditional beliefs and framework of health. Concerns with herbal supplements are related to the often numerous physiologic active components of the herbs, adulterants, inconsistent dosing, and lack of proven efficacy. Herbs taken in late pregnancy may contribute to preterm labor or increased bleeding during delivery. Nurses must be



BEFORE ONSET OF LABOR
STAGE ONE LABOR: CERVICAL EFFACEMENT
STAGE ONE LABOR: CERVICAL DILATATION
STAGE TWO LABOR: EXPULSION

FIGURE 54–1 First and second stages of labor.

culturally sensitive to the use of herbal supplements and health practices during pregnancy, specifically in the latter gestational weeks.

When pharmacologic intervention is needed for pain relief, drugs are used as an adjunct to nonpharmacologic measures. Drugs should be selected not only to decrease the patient's pain but also to minimize side effects for the patient and the fetus or neonate. Pain relief in labor can be obtained with systemic analgesics and regional anesthesia. Analgesics alter the patient's perception and sensation of pain without producing unconsciousness.

Analgesia/Sedation

Systemic medications used during labor include sedative-tranquilizers, narcotics agonists, and mixed narcotic agonist-antagonists; these may be administered orally (sedative-hypnotic drugs), intravenously (IV), or intramuscularly (IM) (Table 54-1). Because of the variable response and blood levels with intramuscular administration, these drugs are more commonly administered intravenously. These medications should be administered at the onset of the uterine contraction, because parenteral administration at the onset of the contraction decreases neonatal drug exposure as blood flow is decreased to the uterus and fetus.

The sedative-tranquilizer drugs are most commonly given for false labor, latent labor, or with ruptured membranes without true labor. These drugs may also be administered to minimize maternal anxiety and fear. These drugs promote rest and relaxation and decrease fear and anxiety, but they do not provide pain relief. The sedative drugs most commonly used are barbiturates or hypnotics—generally secobarbital sodium (Seconal) and pentobarbital sodium (Nembutal). Other drugs, such as phenothiazine derivatives and hydroxyzine, can be given alone during early labor or in combination with narcotic agonists when the patient is in active labor. In addition to decreasing anxiety and apprehension, these drugs potentiate the analgesic action of the opioids and minimize emesis. These drugs include promethazine (Phenergan), a phenothiazine, and hydroxyzine hydrochloride (Vistaril), a sedative-hypnotic.

The second group of drugs given for active labor are the narcotic agonists. These drugs may be administered parenterally or via regional blocks. When administered with neuraxial anesthesia, a lower dose of anesthetic is required for effective pain relief, thereby minimizing side effects. These drugs interfere with pain impulses at the subcortical level of the brain. To effect pain relief, opioids interact with mu and kappa receptors. For example, morphine sulfate activates both mu and kappa receptors.

Meperidine (Demerol) is the most commonly prescribed synthetic opioid for pain control during labor. A second narcotic agonist used for pain relief during labor is fentanyl (Sublimaze). Fentanyl is a short-acting synthetic opioid that is best administered IV because of its short duration of action. Morphine sulfate may also be used for pain control in active labor, but it is less frequently used. High doses of opioids are required for effective labor analgesia when administered parenterally.

The third group of systemic medications used for pain relief in labor are opioids with mixed narcotic agonist-antagonist effects. These drugs exert their effects at more than one site—often an agonist at one site and an antagonist at another. The two most commonly used narcotic-agonist-antagonist drugs are butorphanol tartrate and nalbuphine. A primary advantage of these drugs is their dose-ceiling effect. This means additional doses do not increase the degree of respiratory depression, maternal and/or neonatal, so there is less respiratory depression with these drugs than with opioids. The respiratory depression ceiling effect is believed to result from activation of kappa agonists and weak mu antagonists.

TABLE 54-1 COMMON SYSTEMIC MEDICATIONS USED FOR PAIN RELIEF IN LABOR

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Sedative-Hypnotics		
secobarbital (Seconal)	IM: 50-100 mg; PO: 100-200 mg	To decrease anxiety during latent phase of labor. Onset: 15-30 min; peak: 15-30 min; duration: 1-4 h. No effects on uterine tone or contractility; rapidly crosses placenta; can cause decreased variability in FHR because of decreased CNS control over heart rate. No antagonist for barbiturates, so secobarbital administered only if delivery not expected for 24-48 h. May have prolonged depressant effects on neonate. Excreted in breast milk. Compatible with breastfeeding. May increase CNS depression with alcohol, narcotics, antihistamines, tranquilizers, and monoamine oxidase inhibitors (MAOIs). Avoid valerian, St. John's wort, kava kava, gotu kola. Pregnancy category: D; PB: 45%-60%; $t\frac{1}{2}$: 15-40 h
pentobarbital (Nembutal)	IV: Initial: 100-200 mg	Short-acting barbiturate. Sedative. Pregnancy category: D; PB: Varying degree based upon lipid solubility; $t\frac{1}{2}$: 15-50 h; Onset: IV: Immediate-5 minutes

TABLE 54-1 COMMON SYSTEMIC MEDICATIONS USED FOR PAIN RELIEF IN LABOR—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
promethazine (Phenergan)	IM/IV: 12.5-50 mg q3-4h or IM: 25-50 mg with 25-75 mg meperidine or IV: 15-25 mg with 25-75 mg meperidine; repeat if needed; *max:* 100 mg in 24 h	A phenothiazine antihistamine; used as an adjunct to narcotic analgesics during first stage of labor; antiemetic properties. Onset: IM: 20 min; IV: 3-5 min. Do not give subQ. To prevent or minimize tissue damage during IV administration, dilute, administer via running IV line at port furthest from vein, and administer through large bore vein if possible. Instruct patient to report signs of pain and burning with administration. Used alone to promote rest and sleep; potentiates action of narcotic agonists, reducing narcotic doses. May cause decreased variability in FHR; contraindicated during lactation. At term, rapidly crosses placenta; fetal and maternal blood concentrations in equilibrium in 15 min, with infant levels persisting for 4 h. Transient hypotonia, lethargy, and electroencephalographic changes for 3 days in newborn. May cause maternal tachycardia; may impair newborn platelet aggregation. If given with meperidine, administer slowly at beginning of contraction over several minutes to decrease amount of drug perfused immediately to fetus via placenta. Adverse reactions: dizziness, dry mouth, excessive sedation, weakness, blurred vision, and restlessness. Pregnancy category: C; PB: 35%-55%; t½: 22 h
promethazine HCl (Phenergan)	IV: 12.5-25 mg IM: 25-50 mg q4-6h; repeat if needed For sedation in obstetrics: IM or IV dosage Note: Deep IM injection is the preferred parenteral route of administration. IV administration is the most common route in clinical settings. IV administration has been associated with severe tissue damage. Do not give at a rate >25 mg/min IV; consider dilution prior to administration and giving over 10-15 minutes. Pregnant females: 25-50 mg IM or IV during the early stages of labor and 25-75 mg after labor is established; repeat dosage once or twice every 4 hours as needed; maximum total dose is 100 mg per 24-hour period for patients in labor.	Antianxiety agent; antihistamine; antiemetic; sedative-hypotonic. Used alone early in labor or later to potentiate action of narcotic agonists. Onset: IV: 3-5 min; IM: 20 min; peak: IV/IM: UK; duration: 2-6 h. IV is not preferred route for administration but is frequent route for obstetric patients. Solution for IV may be diluted in 25-100 mL NS or D_5W and infused slowly over 15-30 min at a rate <25 mg/min Use Z-track injection for IM to reduce pain. Intraarterial or subQ administration not recommended (thrombus and digital gangrene can occur). Extravasation can result in sterile abscesses and marked tissue induration. Use with caution in patients with chronic obstructive pulmonary disease and asthma. Crosses placenta. Possible respiratory depression if drug administered near delivery. Can cause decreased variability in FHR. Breastfeeding not recommended. No effect on labor or neonatal Apgar scores. Adverse reactions: hypotension, drowsiness, dizziness, ataxia; may cause CNS depression with alcohol, analgesics, barbiturates, narcotics; may decrease effects of epinephrine. Pregnancy category: C; PB: 93%; t½: 3 h
hydroxyzine pamoate (Vistaril)	Anxiety: PO: 25-100 mg Preoperative sedation: 50-100 mg IM: 25-100 mg	Anxiolytic; antiemetic; antihistamine. Used for anxiety and preoperative and postoperative adjunct for sedation. Onset: 15-30 min; Peak: 2 h; Duration: 4-6 hours. Administer deep in large muscle. Do not give IV or subQ. Additive effects may occur with use of ethanol, St. John's wort, kava kava, anticholinergics, and CNS depressants. Pregnancy category: C; PB: UK; t½: 3-7 h
Narcotic Agonists		
fentanyl citrate (Sublimaze)	IM/IV: 50-100 mcg	IV: Onset: 1-2 min; Peak: 3-5 min; Duration: 30-60 min; IM Onset: 7-15 min; Peak: 20-30 min; Duration: 1-2 h. Is 50-100 times as potent as morphine. Muscle rigidity may occur with too-rapid IV administration. Inject over 3-5 min. Crosses placenta and excreted in breast milk. Watch for respiratory depression in neonates of mothers who receive this drug in labor. May see withdrawal symptoms in neonate if mother was regular opioid user during pregnancy. Be alert to risk of overdose in patients using CNS depressants, phenothiazines, ethanol, and tricyclic antidepressants. Herbal interactions include increased CNS depression with use of St John's wort, kava kava, and gotu kola. Contraindicated in patients with severe asthma. Pregnancy category: C; PB: UK; t½: 2-4 h

Continued

TABLE 54-1 COMMON SYSTEMIC MEDICATIONS USED FOR PAIN RELIEF IN LABOR—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
morphine sulfate (Duramorph)	IM/IV: 5-10 mg or IV 2-5 mg q4h	Opioid; binds to CNS opiate receptors and inhibits ascending pain pathways. Used for relief of moderate to severe pain, for preoperative medication, and as supplement to anesthesia. Onset: IM: 20-30 min; IV: 3-10 min. Peak: IM: 0.5-1 h; IV: 20 min. Duration: IM: 3-4 h; IV: 3-5 h. Have naloxone available as antidote. If naloxone is necessary for maternal and fetal respiratory depression, give to mother and infant. CNS depressants and tricyclic antidepressants may potentiate effects of morphine. Cautious use with MAOIs and meperidine. Use of selective serotonin reuptake inhibitors (SSRIs) or meperidine may precipitate serotonin syndrome. Use with caution in patients with biliary tract disease and seizure disorders. Withdrawal symptoms may occur in narcotic-dependent patients and in neonates of narcotic-dependent patients. May cause drowsiness and respiratory depression, sedation, euphoria, hallucinations, headache, and palpitations. Do not give if respirations <12/min. Morphine crosses placenta. Use with caution in patients delivering a preterm infant, because fetus may exhibit decreased beat-to-beat variability on FHR monitor. Newborn may have moderate CNS depression, hypotonia at birth, and mild behavioral depression. When giving IV, dilute in 4-5 mL of sterile water and administer slowly (15 mg over 3-5 min). Herbal interactions include increased CNS depression with valerian, St. John's wort, kava kava, and gotu kola. Enters breast milk; compatible with breastfeeding for single doses of morphine. Chronic morphine use may have adverse neonatal effects and is not recommended. Pregnancy category: C (D, if prolonged use or high at-term dose); PB: 30%-35%; $t\frac{1}{2}$: 2-4 h
Mixed Narcotic Agonist-Antagonists		
butorphanol tartrate	IV: 0.5-1 mg q1.5-2h or 1-2 mg q4h	Mixed opioid agonist/antagonist. IV onset: 5-10 min; peak: 4-5 min; duration: 3-4 h. Herbal interactions include increased CNS depression with valerian, St John's wort, kava kava, and gotu kola. Contraindicated for opiate-dependent patients who have not been detoxified; may cause withdrawal syndrome. Cautious use in patients with renal or hepatic dysfunction. For use in pregnancies >37 gestational weeks with no fetal distress. Use alternative analgesic if delivery anticipated in 4 h or less. If breastfeeding, take dose immediately after breastfeeding or 3-4 hours prior to next feeding. Pregnancy category: C/D; PB: 80%; $t\frac{1}{2}$: 2.5-4 h
nalbuphine	IV: 10 mg q2-3h	Mixed opioid agonist/antagonist. Narcotic. Onset: 2-3 m; Peak: 2-3 min; Duration: 3-6 h. Limited respiratory depression. Less analgesic effect than morphine. About 10%-15% of laboring women experience hallucinations with nalbuphine. Cautious use in patients with renal or hepatic dysfunction. Avoid use in opiate-dependent patients; may cause withdrawal syndrome. Monitor for fetal bradycardia. Monitor newborn for respiratory depression or bradycardia. Inject slowly over at least 2-3 min. If breastfeeding, take immediately after breastfeeding or 3-4 h prior to next feeding. Herbal interactions include increased CNS depression with valerian, St. John's wort, kava kava, and gotu kola. Toxicity can be reversed with naloxone. Pregnancy category: B; PB: UK; $t\frac{1}{2}$: 5 h

CNS, Central nervous system; *d,* day; *FHR,* fetal heart rate; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *subQ,* subcutaneously; $t\frac{1}{2}$, half-life; *UK,* unknown; <, less than, >, greater than.

Adverse Reactions

Adverse effects of sedative-hypnotic drugs (secobarbital, pentobarbital) include paradoxically increased pain and excitability, lethargy, subdued mood, decreased sensory perception, and hypotension. Fetal and neonatal side effects include decreased fetal heart rate (FHR) variability and neonatal respiratory depression, sleepiness, hypotonia, and delayed breastfeeding with poor sucking response for up to 4 days.

Side effects of phenothiazine derivatives and antiemetics/antihistamines (promethazine, hydroxyzine) include confusion, disorientation, excess sedation, dizziness, hypotension, tachycardia, blurred vision, headache, restlessness, weakness, and urinary retention with promethazine, and drowsiness, dry mouth, dizziness, headache, blurred vision, dysuria, urinary retention, and constipation with hydroxyzine. Decreased FHR variability occurs, and the neonate can experience moderate central nervous system (CNS) depression, hypotonia, lethargy, poor feeding, and hypothermia.

The adverse effects of opioids depend on the responses activated by the mu and kappa receptors. Activation of mu receptors results in analgesia, decreased gastrointestinal (GI) motility, euphoria, respiratory depression, sedation, and physiologic dependence. In contrast, activation of kappa receptors results in analgesia, decreased gastrointestinal motility, miosis, and sedation. When parenterally administered, the side effects of opioids include nausea, vomiting, sedation, orthostatic hypotension, pruritus, and maternal and neonatal respiratory depression. The associated nausea and vomiting result from stimulation of the chemoreceptor trigger zone in the medulla. Motor block is another concern. Mothers may not walk after delivery until they are able to maintain a straight leg raise against downward pressure as applied by the practitioner. Fetal and neonatal effects include decreased FHR variability and depression of neonatal respirations and Apgar scores. Depression of neonatal neurobehavior is evidenced by lowered Apgar scores. For example, with meperidine, neonatal respiration occurs within 2 to 3 hours after administration. Neonatal respiratory depression may require reversal by administration of naloxone (Narcan). Through inhibition of both mu and kappa receptors, naloxone may reverse the effects of opioids. Note: With maternal administration of naloxone, there will be a subsequent increase in pain.

Narcotic agonist drugs (morphine, fentanyl) can cause orthostatic hypotension, nausea, vomiting, headache, sedation, hypotension, and confusion. Decreased FHR variability and neonatal CNS depression can occur with meperidine.

Mixed narcotic agonist-antagonist drugs (butorphanol tartrate, nalbuphine) can cause nausea, clamminess, sweating, sedation, respiratory depression, vertigo, lethargy, headache, and flush. Side effects in the fetus and neonate include decreased FHR variability, moderate CNS depression, hypotonia at birth, and mild behavioral depression.

Nursing Process
Patient-Centered Collaborative Care

Pain-Control Drugs

Assessment
- Assess patient's level of pain using agency pain scale.
- Assess patient's cultural framework to determine use of complementary and alternative medicine in later pregnancy and beliefs regarding labor.
- Assess laboring patient's behavior for relaxation and progress of labor in relation to expected norms.
- Assess patient's verbal and nonverbal behavior for data supportive or nonsupportive of coping with labor.
- To determine effectiveness of pain management, obtain baseline vital signs, blood pressure (BP), breath sounds, quality of uterine contractions, degree of effacement and dilation, and FHR before administering analgesic.
- Ask patient regarding use of complementary and alternative medicines (including herbal supplements) during pregnancy.
- Screen for drug history to ascertain potential for drug-drug interactions.
- Assess cultural expectations related to pain experiences.

Nursing Diagnoses
- Anxiety related to uncertainty about labor experience and personal coping ability
- Acute pain related to processes of labor and birth
- Fear related to deficient knowledge of processes and birth and expected sensations with analgesic interventions

Planning
- Patient will verbalize desired amount of pain relief during labor.
- Patient will demonstrate minimal to no side effects from pain-control drugs during labor.
- Patient will verbalize a decrease in pain on a scale of 1 to 10 or per agency pain scale.

Nursing Interventions
- Offer appropriate analgesia for stage and phase of labor and anticipated method of delivery. Encourage patient and support persons to participate in decision making about analgesia.
- Document administration of drug per agency protocol.
- Provide appropriate safety measures after administration of drugs.
- Check compatibility chart for any mixing of drugs.
- Verify that correct antidote drugs are available.
- Within agency protocol, safe obstetric practice, and patient preferences, administer drugs before maximum intensity of pain and anxiety.
- Assess patient's level of pain using agency-appropriate pain scale 30 to 60 minutes after analgesic administration.

Sedative-Hypnotics: Barbiturates
- Do not give if active labor is imminent.
- Monitor FHR; expect decreased variability.

Phenothiazine Derivatives
Promethazine (Phenergan)
- If administered by IV route, give at onset of uterine contraction. Administer at a rate not to exceed 25 mg/min.

- Monitor amount of promethazine patient receives in 24 hours; monitor maternal heart rate after administration.

Hydroxyzine (Vistaril)

- Administer IM (Z-track technique) only. Do not give subcutaneously or IV.

Narcotic Agonists and Mixed Narcotic Agonist-Antagonists

- Assess patient parity, obstetric delivery history, and anticipated time until delivery.
- Because of risk of neonatal respiratory depression, do not administer when delivery is likely within 2 hours.
- Monitor urine output.
- Monitor FHR, assessing for fetal well-being before and during drug administration.

Fentanyl

- Generally not given before active labor. Have naloxone available as antidote if needed.
- If drug is administered IV, administer slowly at beginning of contraction over several minutes to decrease amount of drug perfused to the fetus via the placenta.
- Assess respirations. Must be >12 before administration.
- Provide restful environment as adjunctive therapy.
- Keep bed rails up when patient is nonambulatory, and have patient solicit assistance with ambulation.
- Monitor FHR, assessing for fetal well-being before and during drug administration.
- Have neonatal naloxone available.

Butorphanol Tartrate

- Monitor for signs of narcotic withdrawal in narcotic-dependent patients.
- Monitor for maternal and/or neonatal respiratory depression.
- Assess respirations. Must be >12 before administration.
- IM: Inject deep into muscle. IV: Give slowly at onset contraction. Do not administer subcutaneously.
- Provide restful environment as adjunctive therapy.
- Monitor FHR tracing, assessing for fetal well-being before and during drug administration.
- Keep bed rails up when patient is nonambulatory, and have patient solicit assistance with ambulation.
- Have naloxone available.

Patient Teaching

General

- Advise patient concerning (1) drugs ordered, (2) route of administration and reason, (3) expected effects of drug on labor, and (4) potential drug effects on patient and fetus or neonate.
- Educate patient that most drugs used for pain relief in labor and delivery are not given by mouth, because the gastrointestinal tract functions more slowly during labor, and drug absorption is decreased, making the oral route ineffective.
- Advise patient about safety precautions to be used while receiving the drug, including (1) positioning in bed, (2) use of side rails, and (3) assistance with ambulation.

Cultural Considerations

- Acknowledge and incorporate patient's cultural belief framework into nursing care.
- Assess patient's use of complementary and alternative medicine (to include herbal supplements) during pregnancy and labor.
- Recognize cultural influences on patient's expression of discomfort and pain.
- Provide an interpreter as appropriate.

Evaluation

- Evaluate effectiveness of drug in alleviating pain.
- Evaluate fear and anxiety in regard to pain and ability to cope with labor.
- Monitor maternal respirations, heart rate, BP, uterine contractions, dilatation and effacement, and FHR for alterations from baseline. Report deviations beyond those expected with normally progressing labor.
- Document findings, using agency protocol and obstetric nursing standards of care.

Anesthesia

Anesthesia in labor and delivery represents the loss of painful sensations with or without loss of consciousness. Two types of pain are experienced in childbirth. Visceral pain from the cervix and uterus is carried by sympathetic fibers and enters the neuraxis at the thoracic 10, 11, 12, and lumbar 1 spinal levels. Early labor pain is transmitted to T11 and T12 with later progression to T10 and L1. Somatic pain is caused by pressure of the presenting part and stretching of the perineum and vagina. This pain is the pain of the transition phase and the second stage of labor and is transmitted to the sacral 2, 3, and 4 areas by the pudendal nerve.

Regional Anesthesia

Regional anesthesia achieves pain relief during labor and delivery without loss of consciousness. Injected local anesthetic agents temporarily block conduction of painful impulses along sensory nerve pathways to the brain (Table 54-2). Regional anesthesia allows the patient to experience labor and childbirth with relief from discomfort in the blocked area. There are primarily two types of anesthesia: (1) local anesthetic agents for local infiltration (e.g., episiotomy) and (2) regional blocks (e.g., epidural; Table 54-3). The most common peridural anesthesias are spinal, epidural, and combined spinal-epidural (Figure 54-2). Other less commonly administered regional blocks include caudal, paracervical, and pudendal blocks. The anesthesiologist or nurse anesthetist is responsible for administering regional anesthesia.

TABLE 54-2 ANESTHETIC AGENTS USED IN OBSTETRICS

ANESTHETIC AGENT	USUAL CONCENTRATION	USUAL DOSE (mg)	ONSET	AVERAGE DURATION (min)	CLINICAL USE
Chloroprocaine	1-2	400-600	Rapid	15-30	Local or pudendal block
(Nesacaine)	2-3	300-750		30-60	Epidural
Tetracaine	0.2	4	Slow	70-150	Low spinal block
(Pontocaine)	0.5	7-10	Fast	75-150	Spinal for cesarean
Lidocaine	1	200-300	Rapid	30-60	Local or pudendal block
(Xylocaine)	2	300-450		60-90	Epidural for cesarean
	5	50-75		45-60	Spinal for cesarean, PP tubal ligation, and vaginal delivery
Bupivacaine	0.5	50-100	Slow-moderate	90-150	Epidural for cesarean
(Marcaine)	0.25	20-25	Moderate	60-90	Epidural for labor
	0.75	7.5-11		60-120	Spinal for cesarean
Ropivacaine	0.5	75-100	Slow-moderate	90-150	Epidural for cesarean
(Naropin)	0.25	20-25	Slow-moderate	60-90	Epidural for labor

min, Minute; *PP,* postpartum.

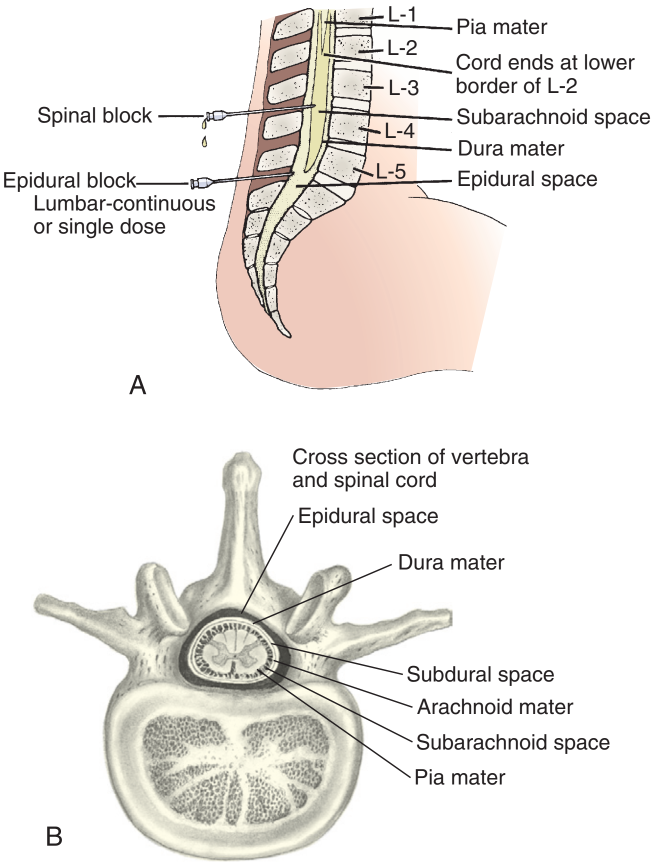


FIGURE 54–2 **A,** Membranes and spaces of spinal cord and levels of sacral, lumbar, and thoracic nerves. **B,** Cross-section of vertebra and spinal cord. (From Lowdermilk D, Perry S, Cashion C, Alden K: *Maternity and women's health care,* ed 10, St. Louis, 2012, Mosby.)

Nurses may assist with administration of anesthesia and monitor the patient for drug effectiveness and side effects during and after administration.

Women receiving parenteral analgesic for labor and delivery may require more focused anesthesia for episiotomies and repair of perineal lacerations. Local anesthetic agents may be administered alone, and the anesthetic agent primarily administered is lidocaine (Xylocaine). Burning at the site of injection is the most common side effect.

Spinal anesthesia, also known as a *saddle block,* is injected in the subarachnoid space at the T10 to S5 dermatome. This anesthesia may be a single dose or administered as a combined spinal-epidural. Spinal anesthesia is administered immediately before delivery or late in the second stage when the fetal head is on the perineal floor. Drugs frequently administered either alone or in combination with the local anesthetic for a vaginal delivery include bupivacaine (Marcaine) (2.5 to 3 mg) with fentanyl (25 mcg). Dosages vary depending on whether administration of the anesthetic agent is plain or with epinephrine. Spinal anesthesia has a rapid onset, requires less local anesthetic, and may be used with high-risk patients. Postdural puncture headache is a primary concern, occurring 6 to 48 hours after dural puncture; it may also occur after accidental dural puncture with epidural anesthesia. Treatment for postdural headache includes analgesics, increased fluids, and bed rest. With resistant headaches, some health care providers may give 500 mg of caffeine in 1000 to 2000 mL of normal saline over 2 hours, though caffeine preparations have not been proved to be effective. An epidural blood patch (10 to 20 mL) is the most effective means to treat postdural headache.

Lumbar epidurals may be administered as a single injection, intermittent injections, continuous patient-controlled epidural anesthesia (PCEA), and as a combined spinal-epidural. Epidurals may be administered as a single anesthetic agent or with opioids or epinephrine. Single-dose epidural anesthesia is infrequently used as analgesia and is limited to the single dosing action. Intermittent epidural bolus dosing was once commonly used for pain relief. Doses of the local anesthetic were injected intermittently via an epidural catheter. Limitations of this method included the need for frequent injections and decreased pain control because of the dosing schedule. Most frequently, patients now

TABLE 54-3 TYPES OF ANESTHESIA

TYPE OF ANESTHESIA	INDICATIONS	ADVERSE REACTIONS/ SIDE EFFECTS*	NORMAL DOSE	NURSING IMPLICATIONS†
Spinal block (subarachnoid block)	Need for high degree of pain relief for delivery.	High/spinal block (respiratory muscles impaired by block), neuritis, block failure, apnea with total spinal	Vaginal delivery: 2.5 or 3 mg bupivacaine (Marcaine) with 25 mcg fentanyl (Sublimaze). Epinephrine 0.2 mg and fentanyl 10-25 mcg or sufentanil (Sufenta) 5-10 mcg or morphine (Duramorph) 0.1-0.25 mg Cesarean delivery: 12 mg bupivacaine mixed with 8.25% dextrose with 10-25 mcg fentanyl. Postoperatively 0.1-0.25 mg morphine may be added	Cervix should be fully dilated before administration. Anesthetic should be given immediately after a contraction to avoid impairing neonate's respiratory efforts. Patient is generally placed sitting or in curled side-lying position for administration. Monitor BP every 1-2 minutes for first 10 minutes. After administration, monitor BP every 5-10 minutes. Assess level of analgesia. Treat maternal hypotension due to uterine displacement by placing a wedge under hip. Contraindications: Infection at site, increased intracranial pressure, allergy to local anesthetics, coagulopathies, severe hypovolemia, severe aortic or mitral stenosis, or lack of patient consent.
Lumbar epidural block (single dose)	Pain relief in first and second stages of labor.	Neuritis, epidural hematoma, high/ spinal block, catheter complications, intravascular injection, direct spinal cord injury, bloody tap.	Vaginal delivery: bupivacaine (Marcaine) 0.125% to 0.25%, lidocaine (Xylocaine) 1.5%, with 1:200,000 epinephrine followed by 0.1%-0.2% ropivacaine (Naropin) with fentanyl (Sublimaze) 2 mcg/mL. Cesarean delivery: 5 mL boluses of 2% lidocaine with 1:400,000 epinephrine, alternatively, 5 mL boluses of 0.5% bupivacaine or 0.5% ropivacaine or 3% 2-chloroprocaine (boluses of lidocaine or 2-chloroprocaine every 1-2 minutes, boluses of bupivacaine or ropivacaine every 2-5 minutes)	Of particular importance is the assessment of bilateral analgesia for pain relief during labor. If unilateral analgesia occurs, patient is turned to opposite side and more anesthetic is injected. Contraindications: Same as spinal block.

Continuous lumbar epidural block using indwelling catheter in epidural space	Pain relief during first and second stages. The most widely used anesthesia method for labor pain management. Useful for prolonged labor.	Pruritus, catheter complications, intravascular injection, direct spinal cord injury, bloody tap.	Continuous infusion options (rate is 12-15 mL/h): 0.1% or 0.15% ropivacaine or bupivacaine (Marcaine) with 1-2 mcg/mL fentanyl (Sublimaze)	Breakthrough pain is treated by increased infusion rate of rescue dose of anesthetic.
Patient-controlled epidural administration	Pain relief during first and second stages. Useful for prolonged labor.	Same as above.		Same as above.
Combined spinal-epidural	Pain relief during first and second stages. Spinal can help with early labor pain and epidural with pain management during active labor.	Same as above.	Spinal: 10-25 mcg fentanyl (Sublimaze) or 2.5-10 mcg sufentanil (Sufenta) alone or in combination with 1 mL bupivacaine (Marcaine) 0.25% epidural is initiated with bupivacaine 0.03%-0.0625% with fentanyl 1-2 mcg/mL or sufentanil 0.1-0.3 mcg/mL.	Same as above.
Local infiltration	For episiotomy and perineal laceration repair. When given: Just before delivery or repair. Area blocked: Local area adjacent to injection. Injection site: Perineal subcutaneous tissue.	Mild discomfort and/or burning during injection. Fetus or neonate: None.		May not obtain complete pain relief, and may need additional injections; requires large amount of local anesthetic agent.

*The following adverse reactions/side effects apply to each of the above: *Patient:* hypotension; paresthesia or nerve injury, postdural puncture headache, infection, nausea, vomiting, backache, urinary retention. Headache is less common because of the small size (25 gauge) of needle used. *Fetus or neonate:* Few, unless secondary to maternal hypotension, then FHR late decelerations.

†The following nursing considerations apply to all types of epidurals: Test dose (3 mL of lidocaine 1.5% with 1:200,000 epinephrine) is used to confirm correct placement of catheter; if local anesthetic is injected into vein, patient may experience dizziness, ringing in ears, numb mouth, metallic taste, or toxic response. Maternal lateral positioning is done to prevent aortocaval compression. Maternal diastolic BP should be less than 110 mm Hg before initiating the epidural. When maternal hypotension occurs, place patient on her left side, infuse IV fluids rapidly, and administer ephedrine 5 to 15 mg IV or 40 to 80 mcg phenylephrine IV. Repeat as necessary. Monitor BP every 1 to 2 minutes for first 10 minutes, then every 10 to 30 minutes until block wears off. Assess level of analgesia. After administration of the anesthetic, assess motor strength prior to ambulation.

TABLE 54-4 PARENTERAL OPIOIDS FOR LABOR AND DELIVERY

OPIOID	DOSAGE	ANALGESIC EFFECT BEGINS	PEAK ANALGESIC EFFECT	DURATION OF ACTION
meperidine (Demerol)	IM: 50-100 mg	IM: 10-45 min	IM: 30-50 min	IM: 2-4 h
	IV: 25-50 mg	IV: <5 min	IV: 5-10 min	IV: 2-3 h
fentanyl (Sublimaze)	IM: 50-100 mcg	IM: 7-15 min	IM: 30 min	IV: 30-60 min
	IV: 50-100 mcg	IV: Almost immediately	IV: 3-5 min	IM: 1-2 h
morphine sulfate (Duramorph)	IM: 10 mg	IM: 15-60 min	IM: 1-2 h	IM: 3-5 h
	IV: 2-5 mg	IV: 5-10 min	IV: 20 min	IV: 3-5 h
nalbuphine	subQ: 5-10 mg	subQ: <15 min	subQ: N/A	subQ: 3-6 h
	IV: 5-10 mg	IV: <1-3 min	IV: 30 min	IV: 3-4 h
butorphanol	IM: 1-2 mg	IM: 5-10 min	IM: 30-60 min	IM: 3-4 h
	IV: 1-2 mg	IV: <10 min	IV: 4-5 min	IV: 2-4 h

h, Hour; *IM,* intramuscular; *IV,* intravenous; *min,* minute; *subQ,* subcutaneously; <, less than.

receive a continuous epidural infusion, which provides more consistent drug levels and more effective pain relief. Rescue doses are given as necessary to achieve pain relief.

Opioids are administered with the local anesthetic to more effectively control the somatic pain of transition and second-stage labor pain. The opioids most frequently used in combination with the local anesthetic (e.g., 0.125% bupivacaine, 0.2% ropivacaine) are fentanyl or sufentanil (Sufenta). Fentanyl or sufentanil are lipophilic opioids commonly used with continuous or PCEA epidural. These opioids offer rapid analgesia and fewer side effects than hydrophilic opioids. In contrast, morphine sulfate and hydromorphone are hydrophilic opioids. They have a slower onset of action, variable duration, and increased side effects, specifically respiratory depression (Table 54-4).

Another additive to the local anesthetic is epinephrine. Epinephrine increases the duration of the local anesthetic and decreases its uptake and clearance from the cerebrospinal fluid (CSF), while enhancing the intensity of the neural blockade. Single and intermittent injections have wide variations in drug levels and less effectively controlled pain. A continuous lumbar epidural allows a more evenly spaced drug level; less anesthetic is required to provide more effective pain control. Continuous-infusion PCEA gives the patient control of her anesthesia at a basal infusion rate of 10 mL/h, a 5-mL bolus dose, and a 10-minute lockout. Frequently single, intermittent, and PCEA will require rescue doses to improve analgesia.

Lastly, combined spinal-epidural analgesia couples the rapid analgesia and specificity of catheter placement of spinal anesthesia with the continuous infusion via catheter of epidural anesthesia, providing pain relief for later labor.

Controversy exists regarding the effect of regional analgesia, specifically epidurals, on the progress of labor. Some studies indicate no significant effect on labor, whereas other research has demonstrated a decreased maternal urge to push and increased length of labor.

Anesthesia for cesarean deliveries may be general, spinal, or epidural. General anesthesia may be necessary for emergency deliveries, when spinal or epidural anesthesias are contraindicated. It allows for rapid anesthesia induction and control of the airway. Before the administration of general anesthesia, citric acid/sodium citrate (Bicitra) 30 mL is orally administered to decrease gastric acidity. Antacids are administered to decrease complications from gastric acid aspiration. Other medications that may be used in place of citric acid/sodium citrate are cimetidine (Tagamet) 300 mg, ranitidine (Zantac) 50 mg, or metoclopramide 10 mg.

More commonly, spinal or epidural anesthesia is administered for cesarean births. Spinal anesthesia is the more common choice for cesareans because of rapid onset, increased reliability, and improvement in spinal needle design (smaller gauge and shape [Sprotte needle]) with subsequent reduction in postdural headaches. With spinal anesthesia, the local anesthetic most commonly administered is 2.5 or 3 mg bupivacaine (Marcaine) with fentanyl 25 mcg. Pain relief begins in 5 minutes and lasts for approximately 2 hours. The opioids fentanyl 10 to 25 mcg or sufentanil 5 to 10 mcg or morphine (Duramorph) 0.10 to 0.25 mg may also be administered. With the additives, spinal anesthesia provides 18 to 24 hours of pain relief. For epidural inductions, the test dose is given, 3 mL of lidocaine (Xylocaine) 1.5% with 1:200,000 epinephrine followed by administration of local anesthetics: 0.125% to 0.25% bupivacaine or 0.1% to 0.2% ropivacaine with fentanyl 2 mcg/mL. This is followed by a bolus of 15 to 20 mL in divided doses. For an epidural maintenance infusion, 0.1% or 0.15% ropivacaine or bupivacaine with 1 to 2 mcg of fentanyl is continuously infused at 12 to 15 mL/h. Pain relief should begin in 5 to 10 minutes and improve over the next 15 to 20 minutes. The epidural provides pain relief for 18 to 24 hours.

Contraindications to peridural anesthesia are patients with skin infection at the injection site, coagulopathies, active neurologic disease, severe aortic or mitral stenosis, prior sensitivity to an anesthetic agent, and hypovolemia. Of particular importance is patient understanding of the procedure and informed consent.

Adverse effects from local anesthetic agents depend on their chemical properties, but primarily the CNS and cardiovascular systems are affected. CNS effects generally precede cardiovascular effects, with the exception of bupivacaine, in which adverse effects occur at the same drug level. Maternal systemic hypotension is the most frequent complication of regional anesthesia. Adverse CNS effects include dizziness, confusion, headache, slurred speech, metallic taste, nausea, vomiting, seizures, and coma. Cardiovascular symptoms include hypertension and tachycardia initially, followed by hypotension, cardiac arrhythmias, and cardiac arrest. Fetal distress occurs secondary to maternal hypotension and subsequent reduced uteroplacental perfusion.

Adverse effects from regional anesthetics vary, depending on the agent and mode of delivery. With spinal and epidural anesthesia, a primary concern is maternal hypotension. Hypotension is defined as a decrease in systolic BP greater than 20% to 30% of baseline BP or below 100 mm Hg. To decrease maternal hypotension before epidural placement, an IV bolus of 500 to 1000 mL of crystalloids is given. Patients with hypotension are positioned on their left side to facilitate placental perfusion, and then are given a rapid bolus dose of crystalloid IV solution. If the hypotension does not improve with the fluid bolus, then 5 to 10 mg of ephedrine or 40 to 80 mcg of phenylephrine is administered IV and repeated as necessary. Maternal block is a primary consideration and is decreased with administration of lower concentrations of the regional local anesthetics. Women receiving morphine frequently complain of pruritus, which may be effectively relieved with diphenhydramine (Benadryl) administration.

Nursing Process
Patient-Centered Collaborative Care

Regional Anesthetics

Assessment
- Check history for drug sensitivity to local anesthetic agents.
- Assess patient's "labor plan" with expectations for coping with labor and beliefs about use of analgesia and anesthesia.
- Assess knowledge about regional anesthesia.
- Assess cervical dilation and effacement and labor progress.
- Monitor fetal status.
- Review history for contraindications to regional anesthesia; notify anesthesia provider.

Nursing Diagnoses
- Fear related to deficient knowledge of regional anesthesia/analgesia and expected sensations
- Acute pain related to processes of labor and delivery
- Risk for impaired fetal gas exchange, due to maternal hypotension secondary to epidural block
- Ineffective tissue perfusion, maternal/fetal, related to effects of analgesia/anesthesia and maternal position
- Impaired physical mobility secondary to regional anesthesia
- Risk for urinary retention secondary to regional anesthesia

Planning
- Patient will verbalize desired amount of pain relief during labor.
- Patient will remain normotensive and maintain a normal pulse rate; FHR will remain within normal parameters.
- Patient will not experience bladder distention.
- Patient will be able to discuss use of regional anesthesia for labor and delivery pain control.

Nursing Interventions
General
- Assess hydration status before regional anesthesia is given; monitor for anesthetic hypotensive effects. Provide bolus IV fluids as ordered, usually 500 to 1000 mL before regional anesthesia administration.
- Insert an indwelling urinary catheter before administration to monitor maternal fluid status.
- Position and support patient on her left side or as instructed by anesthesia provider.
- Monitor progress of labor for any decrease in frequency or intensity of uterine contractions.
- Monitor maternal vital signs and FHR.
- Have emergency drugs and ephedrine, antihistamines, oxygen, and resuscitation equipment available.
- Be aware of how to place patient in Trendelenburg position (supine on a surface inclined 45 degrees, head at the lower end and legs flexed over the upper end) if necessary.
- Monitor for postdural puncture headache; notify anesthesia provider.

Spinal
- Assess uterine contractions; anesthetic agent must be given immediately after a contraction.
- Monitor BP for hypotensive effects per agency protocol. Have oxygen with positive pressure ventilation equipment readily available.
- Assess level of analgesia following administration and sensory and motor status following delivery.
- Document procedure per agency protocol.

Epidural
- Ensure that patient has 500 to 1000 mL IV bolus of an isotonic solution before the procedure to increase circulatory volume and prevent maternal hypotension.
- Monitor FHR and progress of labor, and keep in mind that anesthetic can inhibit fetal descent.
- Monitor BP for hypotensive effects per agency protocol.
- Assess level of analgesia following administration.
- If maternal hypotension occurs, maintain patient on left side and increase rate of IV fluids. Notify health care provider.

- Assess for bladder distention. If voiding cues are unsuccessful (e.g., placement in semi-Fowler position, privacy, running water over the perineum, running water over the hand), then catheterize.
- Before allowing patient to ambulate after delivery, assess sensory and motor status.
- Conduct ongoing pain assessment. If nature of pain changes, contact anesthesia provider to evaluate anesthesia needs.
- Document procedure per agency protocol.

Caudal

- Place patient in position requested by anesthesia provider for administration.

Paracervical Block

- Maintain continuous FHR monitoring for fetal bradycardia after administration.
- Monitor maternal BP.

Patient Teaching

General

- Discuss technique, potential benefits, and side effects of patient's particular method of anesthesia.

Side Effects

- Instruct patient that regional anesthetics may slow labor and that patient may need a drug to enhance uterine contractions.
- Assess patient for postdural puncture headache after spinal anesthesia or after accidental dural puncture with epidural anesthesia. Instruct patient that bed rest, oral analgesics, caffeine, or an autologous blood patch may be used for headache pain relief.

Skill

- Teach patient how to curl into position for epidural administration.
- Advise patient that forceps or vacuum extraction may be needed for delivery (because of reduction of "urge to push" sensation).
- Teach patient how to assume the left lateral or other position as requested by anesthesia provider for caudal anesthesia.
- Advise patient receiving epidural anesthesia that she will have an IV and close monitoring of FHR and uterine contractions secondary to anesthesia.

Evaluation

- Evaluate BP compared with preprocedure baseline; evaluate FHR for alterations in variability and for decelerations.
- Evaluate effectiveness of anesthetic in relieving discomfort. Evaluate for uniformity of anesthesia; if there is lateralization or if it is "patchy," notify anesthesia provider.
- Assess for bladder distention. If voiding cues are unsuccessful, then catheterize.
- Before allowing patient to ambulate after delivery, assess sensory and motor status.
- Evaluate uterine fundus for firmness.

Spinal Block (Subarachnoid Block)

Adverse Reactions

Patient: Hypotension; paresthesia or nerve injury, high/spinal block (respiratory muscles are impaired by block), postdural puncture headache, neuritis, block failure. Headache is less common because of small size (25 gauge) of needle used. Patient may have nausea, vomiting, backache, urinary retention, apnea with total spinal, or infection. Fetus or neonate: None, unless secondary to maternal hypotension, then FHR late decelerations.

Normal Dose

Vaginal delivery: Fentanyl 25 mcg with or without bupivacaine 2.5 to 3 mg injected intrathecally into subarachnoid space. Cesarean delivery: 12 mg bupivacaine mixed with 8.25% dextrose for T2 to T4 sensory levels, with fentanyl 10 to 25 mcg added to minimize visceral discomfort. Postoperatively, 0.1 to 0.25 mg morphine may be added to local anesthetic.

Nursing Implications

Patient must be well hydrated; administer bolus of 500 to 1000 mL crystalloid solution as ordered. Cervix should be fully dilated before administration. Anesthetic should be given immediately after a contraction to avoid impairing neonate's respiratory efforts. Patient is generally placed sitting or in curled side-lying position for administration. Monitor BP every 1 to 2 minutes for the first 10 minutes. After administration, monitor BP every 5 to 10 minutes. Assess level of analgesia. Place a wedge under the patient's hip to treat maternal hypotension caused by uterine displacement. If patient receives morphine, monitor for respiratory depression and pruritus.

Contraindications

Infection at puncture site, increased intracranial pressure, allergy to local anesthetics, coagulopathies, severe hypovolemia, severe aortic or mitral stenosis, or lack of patient consent.

Indication

Need for high degree of pain relief for delivery. Used primarily for cesarean delivery, forceps delivery, or in the postpartum period for repair of traumatic lacerations of the perineum or removal of retained placenta; infrequently used for labor. When given: Immediately before delivery; late in second stage when fetal head is on the perineum (for vaginal delivery). Area blocked: Umbilicus to toes with vaginal delivery. Immediately below xyphoid process to toes with cesarean delivery.

Injection site: With patient in sitting or side-lying position, anesthetic injected into subarachnoid space at L4-L5.

Lumbar Epidural Block (Single Dose)

Adverse Reactions

Patient: Hypotension, paresthesia or nerve injury, neuritis, postdural headache with accidental puncture of dura, epidural hematoma, and high/total block (respiratory muscles are impaired by block). Headache is less common because of small size (25 gauge) of needle used. Patient may have nausea, vomiting, backache, urinary retention, infection, catheter complications, intravascular injection, direct spinal cord injury, and bloody tap. Fetus or neonate: Few, unless secondary to maternal hypotension, then FHR late decelerations.

Normal Dose

Vaginal delivery: A test dose is given, 3 mL of lidocaine 1.5% with 1 : 200,000 epinephrine, followed by administration of local anesthetics: 0.1% or 0.125% bupivacaine or ropivacaine with fentanyl 2 mcg/mL). This is followed by a bolus of 15 to 20 mL in divided doses and a continuous infusion at 12 to 15 mL/h; cesarean delivery: nonemergent cesarean: 2% lidocaine (with or without sodium bicarbonate) with 1 : 400,000 epinephrine. Fentanyl 50 to 100 mcg may be added to minimize pain with uterine manipulation. For patients who have an epidural catheter already placed and then require an emergent cesarean, a bolus dose of 15 to 20 mL of 3% 2-chloroprocaine (boluses of lidocaine or 2-chloroprocaine 3% every 1 to 2 minutes, boluses of bupivacaine or ropivacaine (Naropin) every 2 to 5 minutes) is used. As with the spinal, 3 mg morphine may be added and the need to monitor for respiratory depression and pruritus.

Nursing Implications

Before epidural, patient is well hydrated with 500 to 1000 mL of dextrose-free intravenous fluids. A test dose (3 mL of lidocaine with 1 : 200,000 epinephrine) is administered by the anesthesiologist or nurse anesthetist and used to confirm correct placement of catheter; if local anesthetic is injected into vein, patient may experience dizziness, ringing in ears, numb mouth, metallic taste, or toxic response. Loss or reduction of bearing-down reflex means low forceps or vacuum extraction may be needed for delivery. It may slow progress of labor. Maternal lateral positioning is done to prevent aortocaval compression. Maternal diastolic BP should be less than 110 mm Hg before initiating the epidural. When maternal hypotension occurs, place the patient on her left side, infuse IV fluids rapidly, and administer ephedrine 5 to 15 mg IV or 40 to 80 mcg phenylephrine IV and repeated as necessary. Monitor BP every 1 to 2 minutes for the first 10 minutes, and then every 10 to 30 minutes until the block wears off. Assess level of analgesia. After delivery, assess motor strength prior to ambulation. Of particular importance is the assessment of bilateral analgesia for pain relief during labor. If unilateral analgesia occurs, patient is turned to opposite side, and more anesthetic is injected.

Contraindications

Infection at site, increased intracranial pressure, allergy to local anesthetics, coagulopathies, severe hypovolemia, severe aortic or mitral stenosis, or lack of patient consent.

Indication

Pain relief in first and second stages of labor. When given: Active labor, 5 to 6 cm dilated in a primipara, 3 to 4 cm in a multipara. Area blocked: T12-S5 (entire pelvis) in area of dorsal root ganglion, with varying degrees of motor and sensory loss depending on dosage and agent injected. Injection site: Epidural space (potential space between the dura mater and vertebral canal from cranium to sacrum) at L2-L3, L3-L5, or L4-L5; not in the dura. Never injected above L1, where the spinal cord ends. Nerves run off and down the spinal canal, where they free-float and are easily moved aside by the epidural needle. The goal is to bathe the nerves with dispersed local anesthetic.

Continuous Lumbar Epidural Block Using Indwelling Catheter in Epidural Space

Adverse Reactions

Patient: Hypotension, paresthesia or nerve injury, postdural headache with accidental puncture of dura. Headache is less common because of small size (25 gauge) of needle used. Patient may have nausea, vomiting, backache, urinary retention, infection, catheter complications, intravascular injection, direct spinal cord injury, and bloody tap. Fetus or neonate: Few, unless secondary to maternal hypotension, then FHR late decelerations.

Normal Dose

Continuous infusion options (rate is 12 to 15 mL/h): bupivacaine or ropivacaine 0.1% or 0.15% 0.0625% to 0.2% with fentanyl 1 to 2 mcg.

Nursing Implications

Before epidural, patient is well hydrated with 500 to 1000 mL of dextrose-free IV fluids. Test dose (3 mL of lidocaine with 1 : 200,000 epinephrine) is administered by the anesthesiologist or nurse anesthetist and used to confirm correct placement of catheter; if local anesthetic is injected into vein, patient may experience dizziness, ringing in ears, numb mouth, metallic taste, or toxic response. Loss or reduction of bearing-down reflex means low forceps or vacuum extraction may be needed for delivery. May slow progress of labor. Maternal lateral positioning is done to prevent aortocaval compression. Maternal diastolic BP should be less than 110 mm Hg before initiating the epidural. When maternal hypotension occurs, place the patient on her left side, infuse IV fluids rapidly, and administer ephedrine 5 to 15 mg IV. Monitor BP every 1 to 2 minutes for the first 10 minutes and then every 10 to 30 minutes until the block wears off. Assess level of analgesia. After administering the anesthetic, assess motor strength before ambulation. Breakthrough pain is treated by increased infusion rate of rescue dose of anesthetic.

Indication

Pain relief during first and second stages. This is the most widely used anesthesia method for labor pain management. Useful for prolonged labor. When given: Progressive active labor, 5 to 6 cm dilated in a primipara, 3 to 4 cm in a multipara. Area blocked: Same as for lumbar epidural block. Injection site: Same as for lumbar epidural block.

Advantages

Provides continuous anesthesia from stage 1 through delivery and perineal repair. Patient can feel movement and pressure but no pain. Can be used for vaginal delivery or cesarean birth. Sensory level can be altered and density of the block can be manipulated. Can be used to deliver epidural morphine PF or fentanyl into epidural space for regional analgesia (highly effective). Patients may experience pruritus, which may be effectively relieved with diphenhydramine or naloxone intravenous infusions.

Considerations

Loss or reduction of bearing-down reflex means that forceps or vacuum extraction may be needed for delivery. Requires an increased amount of local anesthetic agent. Bupivacaine is used in low concentration (as low as 1/16%) and may be combined with fentanyl.

Complications

Same as for lumbar epidural block.

Side Effects

Pruritus (in 2 to 3 hours when drug reaches upper thoracic segments), urinary retention, and nausea and vomiting related to ineffective hydration to prevent hypotension during labor.

Patient-Controlled Epidural Administration (PCEA)

Adverse Reactions

Patient: Hypotension, paresthesia or nerve injury, postdural headache with accidental puncture of dura. Headache is less common because of small size (25 gauge) of needle used. Patient may have nausea, vomiting, backache, urinary retention, infection, catheter complications, intravascular injection, direct spinal cord injury, and bloody tap. Fetus or neonate: Few, unless secondary to maternal hypotension, then FHR late decelerations.

Nursing Implications

Before epidural, patient should be well hydrated with 500 to 1000 mL of dextrose-free IV fluids. Test dose (3 mL of lidocaine with 1 : 200,000 epinephrine) is used to confirm correct placement of catheter; if local anesthetic is injected into vein, patient may experience dizziness, ringing in ears, numb mouth, metallic taste, or toxic response. Loss or reduction of bearing-down reflex means low forceps or vacuum extraction may be needed for delivery. May slow progress of labor. Maternal lateral positioning is done to prevent aortocaval compression. Maternal diastolic BP should be less than 110 mm Hg before initiating the epidural. When maternal hypotension occurs, place the patient on her left side, infuse IV fluids rapidly, and administer ephedrine 5 to 15 mg IV or phenylephrine 40 to 80 mcg IV. Repeat as necessary. Monitor BP every 1 to 2 minutes for the first 10 minutes and then every 10 to 30 minutes until the block wears off. Assess level of analgesia. After delivery, assess motor strength before ambulation. Breakthrough pain is treated by increased infusion rate of rescue dose of anesthetic.

Indication

Pain relief during first and second stages. Useful for prolonged labor. When given: Progressive active labor, 5 to 6 cm dilated in a primipara, 3 to 4 cm in a multipara. Area blocked: Same as for lumbar epidural block. Injection site: Same as for lumbar epidural block.

Advantages

Provides continuous anesthesia from stage 1 through delivery and perineal repair. Patient can feel movement and pressure but no pain. Patient is in control, and dose may be self-titrated according to her perception of pain. Sensory level can be altered and density of the block can be manipulated. Can be used to deliver epidural morphine PF or fentanyl into epidural space for regional analgesia (highly effective). Patients may experience pruritus, which may be effectively relieved with diphenhydramine or naloxone infusions.

Considerations

Loss or reduction of bearing-down reflex means that forceps or vacuum extraction may be needed for delivery. Requires an increased amount of local anesthetic agent. Bupivacaine is used in low concentration (as low as 1/16%) and may be combined with fentanyl.

Complications

Same as for lumbar epidural block.

Side Effects

Pruritus (in 2 to 3 hours when drug reaches upper thoracic segments), urinary retention, and nausea and vomiting related to ineffective hydration to prevent hypotension during labor.

Combined Spinal-Epidural

Adverse Reactions

Patient: Hypotension, paresthesia or nerve injury, postdural headache. Headache is less common because of small size (25 gauge) of needle used. Patient may have nausea, vomiting, backache, urinary retention, infection, catheter complications, intravascular injection, direct spinal cord injury, and bloody tap. Proper catheter placement is not assured; this becomes a problem if an epidural catheter is needed for emergency analgesic administration. Fetus or neonate: Few, unless secondary to maternal hypotension, then FHR late decelerations.

Normal Dose

Spinal: 10 to 25 mcg fentanyl or 2.5 to 10 mcg sufentanil alone or in combination with 1 mL bupivacaine 0.25% epidural is initiated with bupivacaine 0.03% to 0.0625% with fentanyl 1 to 2 mcg/mL or sufentanil 0.1 to 0.3 mcg/mL.

Nursing Implications

Before epidural, patient is well hydrated with 500 to 1000 mL of dextrose-free IV fluids. Test dose (3 mL of lidocaine with 1:200,000 epinephrine) is used to confirm correct placement of catheter; if local anesthetic is injected into vein, patient may experience dizziness, ringing in ears, numb mouth, metallic taste, or toxic response. Loss or reduction of bearing-down reflex means low forceps or vacuum extraction may be needed for delivery. May slow progress of labor. Maternal lateral positioning is done to prevent aortocaval compression. Maternal diastolic BP should be less than 110 mm Hg before initiating the epidural. When maternal hypotension occurs, place the patient on her left side, infuse IV fluids rapidly, and administer ephedrine 5 to 15 mg IV or phenylephrine 40 to 80 mcg IV. Repeat as necessary. Monitor BP every 1 to 2 minutes for the first 10 minutes and then every 10 to 30 minutes until the block wears off. Assess level of analgesia. After delivery, assess motor strength before ambulation. Breakthrough pain is treated by increased infusion rate of rescue dose of anesthetic.

Indication

Pain relief during first and second stages. Spinal can help with early labor pain and epidural with pain management during active labor. When given: Progressive active labor. Area blocked: Same as for spinal and lumbar epidural block. Injection site: Same as for spinal and lumbar epidural block.

Advantages

Provides continuous anesthesia from stage 1 through delivery and perineal repair. Patient can feel movement and pressure but no pain. Sensory level can be altered and density of the block can be manipulated. Can be used to deliver epidural morphine PF or fentanyl into epidural space for regional analgesia (highly effective). Patients may experience pruritus, which may be effectively relieved with diphenhydramine or naloxone. Administration of a combination of local anesthetic and opioid more effectively blocks the somatic pain of transition and second-stage labor.

Considerations

Loss or reduction of bearing-down reflex means that forceps or vacuum extraction may be needed for delivery. Requires an increased amount of local anesthetic agent. Bupivacaine is used in low concentration (as low as 1/16%) and may be combined with fentanyl.

Complications

Same as for lumbar epidural block.

Side Effects

Pruritus (in 2 to 3 hours when drug reaches upper thoracic segments), urinary retention, and nausea and vomiting related to ineffective hydration to prevent hypotension during labor.

Caudal (Type of Epidural Anesthesia)

Indication

Pain in first and second stages of labor. Infrequently used. When given: Active labor. Area blocked: Perineum; masks uterine contractions. Injection site: Epidural space through sacral hiatus (S4).

Advantages

Useful for women with metabolic, lung, and heart disease. Very rapid perineal anesthesia and muscle relaxation. Can be used continuously.

Considerations

Increased need to use forceps or vacuum extraction because there is a loss of urge to push. Risk of systemic toxic reactions. Level of anesthesia is more difficult to obtain.

Paracervical Block

Indication

Pain during first stage of labor. Due to high incidence of fetal bradycardia, paracervical block is infrequently administered. When given: Active phase of first stage; may be repeated periodically until 8-cm dilated. Area blocked: Uterus, cervix, and vagina; masks uterine contractions. Injection site: Submucosa of the fornix of the vagina lateral to the cervix.

Advantages

Rapid onset. Lasts 60 to 90 minutes. Relieves pain of cervical dilation and contractions. Does not block lower vagina or perineum.

Considerations

Rapid absorption (because injected into a very vascular area). Does not provide anesthesia for delivery or episiotomy repair. Has variable effects on labor progress.

Side Effects

Patient: Hematomas in tissue around injection site. Fetus: Mild to severe bradycardia or prolonged FHR deceleration with decreased variability are common.

Pudendal Block

Indication

For low forceps deliveries, episiotomy, and laceration repair. Infrequently used. When given: Immediately before birth.

Area blocked: Perineum; pudendal nerves. Injection site: Transvaginally, behind each sacrospinous ligament to block pudendal nerves.

Considerations

Not useful for pain management in first stage of labor.

Local Infiltration

Indication

For episiotomy and perineal laceration repair. When given: Just before delivery or repair. Area blocked: Local area adjacent to injection. Injection site: Perineal subcutaneous tissue.

Advantage

No effect on FHR or patient's vital signs.

Considerations

May not obtain complete pain relief, and may need additional injections; requires large amount of local anesthetic agent.

Adverse Effects and Side Effects

Patient: Mild discomfort and/or burning during injection. Fetus or neonate: None.

Relative Contraindications to Regional Anesthesia

The following are relative contraindications to regional anesthesia:

- Severe gestational hypertension (increased risk of profound hypotension associated with underlying disease state)
- Coagulation disorders and risk of bleeding secondary to decreased platelets (patient should have a normal partial thromboplastin time and platelet count)
- Generalized sepsis or local infection at needle insertion site

DRUGS THAT ENHANCE UTERINE MUSCLE CONTRACTILITY

Uterotropic drugs enhance uterine contractility by stimulating the smooth muscle of the uterus. Oxytocin, the ergot alkaloids, and some prostaglandins constitute the uterotropics.

Oxytocin is synthesized in the hypothalamus and is transported to nerve endings in the posterior pituitary gland. The hormone is released by the nerve endings under appropriate stimulation; capillaries absorb the substance and carry it into the general circulation, where it facilitates uterine smooth muscle contraction.

In the presence of adequate estrogen levels (those normally achieved by the third trimester), IV oxytocin stimulates uterine contraction. Oxytocin, prepared in synthetic form and marketed as Pitocin, is approved by the U.S. Food and Drug Administration (FDA) for labor induction and labor augmentation. Box 54-1 presents common medical indications for labor induction.

Before **labor induction** (process of causing or initiating labor) begins, risks and benefits and the status of mother and fetus must be assessed. Informed consent for induction must be obtained. The gestational age of the fetus must be considered, together with position of the fetus (head down and deep in the pelvis) and size of the fetus in relation to the patient's pelvis. The patient's **cervical ripening** (softening of the cervix) is also assessed; the cervix is ripe, and thus ready for induction, when it is soft and progressing in effacement and partial dilation. An objective scoring system called the **Bishop score** (scoring system to assist in predicting whether labor induction may be successful) is used to assess readiness for induction. Elements assessed in the modified Bishop Scoring System are dilation, effacement, station, cervical consistency, and cervical position. Modified Bishop scores of 8 or greater are associated with a successful labor induction.

Some patients are not suitable candidates for labor induction, because the risks of the procedure outweigh the potential benefits. Box 54-2 presents some major contraindications to labor induction.

BOX 54-1 INDICATIONS FOR LABOR INDUCTION

- Gestational hypertension
- Chronic hypertension
- Membrane rupture >24 hours
- Chorioamnionitis
- Postdates (>42 weeks' gestation)
- Intrauterine growth retardation
- Positive contraction stress test
- Maternal diabetes mellitus (classes B-F)
- Maternal renal disease
- Isoimmunization
- Intrauterine fetal death

BOX 54-2 CONTRAINDICATIONS TO LABOR INDUCTION

- Disproportion between fetal head and maternal pelvis (cephalopelvic disproportion)
- Unfavorable fetal presentation (transverse or breech)
- Documented fetal intolerance of uterine contractions
- Prematurity
- Placenta previa or suspected abruptio placentae
- Severe gestational hypertension
- Multiparity (six or more)
- Multifetal gestation
- History of uterine trauma
- Previous major surgery in the area of the cervix or uterus
- Prior classical uterine incision
- Active genital herpes infection
- Umbilical cord prolapse
- Excessive amniotic fluid causing overdistended uterus

Two approaches of labor induction are used to ripen, efface, and begin cervical dilation in pregnant women at term (or near term) with a medical or obstetric indication for labor induction: mechanical methods and *prostaglandins.*

One mechanical method involves insertion of a 36F indwelling catheter through an undilated cervix and internal os with subsequent inflation of the 30-mL balloon. The indwelling catheter bulb provides a mechanical stimulation similar to "stripping of the membranes." When the catheter "falls out," the patient is started on IV oxytocin. A second mechanical method is insertion of an extraamniotic saline infusion with a balloon catheter into the space between the internal cervical os and the placental membrane to induce labor. A third mechanical method is membrane "stripping." With membrane stripping, there is release of prostaglandin F2 from the decidua or prostaglandin E2 from the cervix. Spontaneous labor has been induced within 72 hours of membrane stripping with no increase in infection rates. Amniotomy, artificial rupture of the membranes, is commonly performed in patients with a partially dilated and effaced cervix. When done at 5 cm, dilated spontaneous labor is shortened by 1 to 4 hours without an increase in maternal or fetal complications. With rupture of the membranes, nursing assessment includes assessment of FHR and umbilical cord prolapse. Chorioamnionitis and cord compression have been reported.

The second approach to labor induction uses administration of dinoprostone, the naturally occurring form of prostaglandin E2 (PGE2). It is thought that intracervically or intravaginally administered PGE2 acts to create cervical effacement and softening through a combination of contraction-inducing and cervical-ripening properties, possibly secondary to an increased submucosal water content and collagen degradation resulting from collagenase secretion in response to PGE2. One approach uses prefilled syringes of commercially prepared dinoprostone cervical gel 0.5 mg (Prepidil gel), which is introduced just inside the cervical os. A second approach is the placement in the posterior vaginal fornix of a vaginal insert dinoprostone (Cervidil) containing 10 mg of controlled-release dinoprostone at 0.3 mg/h.

Prostaglandin E1 is also effective in stimulating cervical ripening, although administration is an off-label use. Cytotec or misoprostol (prostaglandin E1) may be administered intravaginally or orally. Dosing ranges from 25 to 100 mcg every 3 to 6 hours.

Side effects associated with the use of prostaglandins include uterine hyperstimulation, which may be treated with terbutaline sulfate. Uncommonly, some patients may experience chills, fever, vomiting, and diarrhea. Contraindications to the use of prostaglandins include active vaginal bleeding and known allergies to prostaglandins. With hepatic or renal disease, cautious use of prostaglandin E2 is recommended; its use is contraindicated in patients with glaucoma. Contraindications for prostaglandin E1 include a previous cesarean delivery or hysterotomy.

Table 54-5 lists the dosages, uses, and considerations for administration of dinoprostone for cervical ripening.

Oxytocin

In addition to labor induction, IV oxytocin can also be used for labor augmentation. It facilitates smooth-muscle contraction in the uterus of a patient already in labor but experiencing inadequate **uterine contractility** (tightening and shortening of uterine muscles). The patient with **uterine inertia** (uterine inactivity or hypotonic contractions) may be more responsive to oxytocin than the patient who has not begun labor; therefore a lower starting dose will be needed.

In both labor induction and **labor augmentation** (stimulation of effective uterine contractions once labor has begun), oxytocin is infused at a prescribed individualized dosage rate, and this rate is increased, decreased, or maintained at fixed intervals based on uterine and fetal response. The objective is to establish an adequate contraction pattern that promotes labor progress, generally represented by contractions every 2 to 3 minutes that last for 50 to 60 seconds with moderate intensity. It is important that the patient receiving oxytocin not experience uterine hyperstimulation, which causes markedly increased pain and compromised FHR patterns secondary to impaired placental perfusion. Continuous nursing observation during labor induction or augmentation is critical. The need for an accurate infusion rate requires the use of an infusion pump with oxytocin as an IV piggyback line. Once cervical dilation has reached 5 to 6 cm, and an adequate contraction pattern is evident, the rate of oxytocin infusion can often be slowed or stopped.

After delivery, oxytocin 20 mg is usually added to an existing IV solution to help the uterus stay contracted and close the uterine sinuses at the placental site. The drug can also be given IM after delivery of the placenta. Prototype Drug Chart 54-1 lists the pharmacologic data for oxytocin.

Oxytocin is well absorbed from the nasal mucosa when administered intranasally for milk letdown. The protein-binding percent is low, and the half-life is 1 to 9 minutes. It is rapidly metabolized and excreted by the liver.

The onset of action of oxytocin administered IM is in 3 to 5 minutes, the peak concentration time is unknown, and the duration of action is 2 to 3 hours. The onset of action of oxytocin administered IV is immediate, the peak concentration time is unknown, and the duration of action is 1 hour. The onset of action of intranasally administered oxytocin is a few minutes, the peak concentration time is unknown, and the duration of action is 20 minutes.

The medication is diluted and administered IV piggyback for induction or augmentation of labor. Oxytocin is diluted in a variety of ways and administered via infusion pump in mL/min dosing with the volume determined by the dilution. IV administration of undiluted oxytocin is not recommended because of the risk of a sudden, acute hypotensive response.

Concurrent use of vasopressors can result in severe hypertension. Hypotension can occur with concurrent use of cyclopropane anesthesia and with undiluted IV push administration. The Institute for Safe Medication Practices (ISMP) includes this medication on its list of high-alert medications that have a heightened risk of causing significant harm when used in error.

TABLE 54-5 DINOPROSTONE FOR CERVICAL RIPENING

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
dinoprostone cervical gel, 0.5 mg (Prepidil gel)	Intracervical: Contains 0.5 mg of dinoprostone in 2.5 mL of gel for intracervical use. Repeat in 6-12 h if negative cervical or uterine response. Maximum 24- h dose is 1.5 mg, supplied in 3 doses. Before beginning oxytocin (Pitocin, Oxytocin) after the Prepidil administration, there should be a 6- to 12-h delay	Naturally occurring form of prostaglandin E2 (PGE2). Used to ripen unfavorable cervix at or near term in pregnant women needing labor induction. Metabolized in lung, liver, and kidney; eliminated by kidney. Patients may have reactive nonstress test before first dose. Monitor uterine activity and FHR; suggest 20-min FHR strip before doses. Must be at room temperature before administration and administered by sterile technique. Must not be placed above level of cervical os. Patient is to remain recumbent 15-30 min following administration of gel and 2 h after insert. May augment other oxytocic agents; therefore no concomitant use; sequential use 6-12 h after gel is recommended. Insert may be inserted with minimal amount of water-soluble lubricant. Wear sterile gloves when administering. See below.* Pregnancy category: C; PB: UK; t½: UK; Onset: 10-60 min; Peak: UK; Duration: 12 h
dinoprostone (Cervidil vaginal inserts)	Vaginal: Contains 10 mg of dinoprostone in a timed-release insert, releasing 0.3 mg/h. Insert is left in place for 12 h. Oxytocin (Pitocin) may be started 30-60 min after removal of insert. In contrast to gel, insert may be removed with FHR decelerations or uterine hyperstimulation. Ripening unfavorable cervix: Intravaginal: 10 mg over 12 h; remove 12 h after insertion or at onset of active labor	Remove insert, and have oxygen or beta-adrenergic drugs to treat uterine hyperstimulation. Use insert at room temperature. Wear sterile gloves to decrease risk of absorption as inserted high into vagina, posterior fornix. Assess cervical dilation and effacement at time of insertion. After administration, patient remains in lying position for 30 min to 2 h. Monitor FHR and uterine stimulation. Have medication available for frequent gastrointestinal side effects of abdominal cramping, diarrhea, nausea, and vomiting. See below.* Assess vaginal discharge. Onset: UK; Peak: UK; Duration: up to 2-3 h. Pregnancy category: C; PB: UK; t½: UK
*dinoprostone cervical gel, 0.5 mg (Prepidil gel) and dinoprostone (Cervidil vaginal inserts)		Wear sterile gloves when administering. Contraindicated in patients with prostaglandin hypersensitivity, cephalopelvic disproportion (CPD), ruptured membranes, and unexplained vaginal bleeding. Use with caution in patients with asthma; seizures; glaucoma; increased intraocular pressure; or cardiovascular, renal, or hepatic disease. Not recommended for patients in whom oxytocic drugs are contraindicated or with prolonged uterine contractions, placenta previa, or active genital herpes (vaginal delivery not indicated). Adverse reactions: uterine hyperstimulation, nausea, vomiting, diarrhea, back pain, warm feeling in vagina, dinoprostone-induced fever, and fetal distress. Treat dinoprostone-induced fever, which occurs in approximately 50% of patients, with tepid baths and increased fluids. Fever is not to be treated with aspirin. Assess vaginal discharge frequently during use.

FHR, Fetal heart rate; *h,* hour; *min,* minute; *PB,* protein-binding; *t½,* half-life; *UK,* unknown.

Nursing Process
Patient-Centered Collaborative Care

Enhancement of Uterine Contractility: Oxytocins

Assessment

- Obtain patient informed consent before inducing or augmenting labor.
- Confirm term gestation before inducing or augmenting labor.
- Collect accurate baseline data before beginning infusion, including maternal pulse and BP, uterine history, uterine activity, and FHR pattern.
- Interview patient and review history to ascertain that there are no contraindications.

Nursing Diagnosis

- Deficient knowledge related to drugs used to promote uterine contractility

PROTOTYPE DRUG CHART 54-1

Oxytocin

Drug Class

Oxytocic agent: Oxytocin
Trade Names: Pitocin
Pregnancy Category: X

Dosage

For induction or augmentation of labor

A: IV: 10 units (1 amp) diluted in 1000 mL lactated Ringer's solution to 10 milliunits/mL. (Resulting concentration is 10 milliunits oxytocin per 1 mL of IV fluid.) Connect to primary IV line close to needle site as a piggyback line. Low-dose oxytocin regimen: start oxytocin at 0.5-1.5 or 2 milliunits/min with an incremental dose of 1-2 milliunits/min or incremental increase of 4 milliunits/min; *max:* 20 milliunits/min unless consult with provider.

High-dose oxytocin regimen: begin oxytocin at 4 or 4.5 or 6 milliunits/min IV with an increase in dose by 4 milliunits/min every 15 min or 4.5 milliunits/min every 15-30 min or 6 milliunits/min every 20-40 minutes; *max:* 40 milliunits/min. unless consult with provider. Postdelivery: A: IV: 10-20 units added to 1000 mL electrolyte or dextrose solution; infuse at rate to prevent uterine atony. IM: 10 units after delivery of the placenta

Nasal spray: 1 spray into one or both nostrils 2-3 min before nursing or pumping; not for use during pregnancy

Contraindications

Contraindicated in vaginal delivery, proven cephalopelvic disproportion, fetal intolerance of labor, hypersensitivity, anticipated nonvaginal delivery, pregnancy (intranasal spray)

Drug-Lab-Food Interactions

Drug: Hypertension with vasopressors, hypotension and/or bradycardia with cyclopropane anesthetics

Pharmacokinetics

Absorption: PO: Not well absorbed; intranasal and IM very rapidly
Distribution: PB: Low; widely distributed in extracellular fluid; minute amounts in fetal circulation
Metabolism: t½: 1-9 min; rapidly metabolized in liver
Excretion: In urine

Pharmacodynamics

IM: Onset: 3-5 min
Peak: 40 min
Duration: 2-3 h
IV: Onset: Within 1 min
Peak: UK
Duration: 1 h
Intranasal: Onset: Few minutes
Peak: UK
Duration: UK

Therapeutic Effects/Uses

To induce or augment labor contractions; to treat uterine atony; to stimulate milk letdown (intranasal spray)

Mechanism of Action: Promotes uterine contractions by increasing intracellular concentrations of calcium in uterine myometrial tissue, thereby increasing the activity of the calcium-dependent phosphorylating enzyme myosin light-chain kinase. The nasal spray works by forcing milk into larger ducts and sinuses. This occurs because oxytocin promotes milk ejection by causing contraction of the smooth-muscle fibers surrounding the breast alveoli and lactiferous ducts.

Side Effects

Maternal effects with undiluted IV use only: hypertension, dysrhythmias, tachysystole, and uterine hyperstimulation. Tachysystole is 6 or more uterine contractions in a 20-min window. (Hyperstimulation is defined as uterine contractions lasting at least 2 min or 5 or more contractions in a 10-min window.)

Adverse Reactions

Seizures, water intoxication if given in electrolyte-free solution or at a rate greater than 20 milliunits/min. (Water intoxication is manifested by nausea, vomiting, hypotension, tachycardia, and cardiac arrhythmias.)

Life-threatening: Patient: Intracranial hemorrhage, cardiac dysrhythmias, asphyxia; fetus: jaundice, hypoxia

A, Adult; *amp,* ampule; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *t ½,* half-life; *UK,* unknown.

Planning

- Oxytocin will enhance uterine contractions without adverse maternal or fetal effects.
- Patient's vital signs will be within acceptable ranges throughout labor, delivery, and postpartum period.
- FHR will demonstrate normal rate, pattern, and variability throughout labor and delivery.

Nursing Interventions

- Have tocolytic agents and oxygen readily available.
- Monitor intake and output.

- Monitor maternal pulse and BP, uterine activity, and FHR during oxytocin infusion.
- Maintain patient in sitting or lateral recumbent position to promote placental infusion.
- Monitor for signs of uterine rupture, which include FHR decelerations, sudden increased pain, loss of uterine contractions, hemorrhage, and rapidly developing hypovolemic shock.
- Use an IV pump when administering.

Patient Teaching

- Inform patient that drug is given IV and dosage adjusted in response to uterine contraction pattern.
- For milk letdown, teach patient timing and method of nasal administration.

Evaluation

- Evaluate for effective labor progress.
- Monitor maternal vital signs every 30 to 60 minutes and with every increment in dose, and FHR every 15 minutes and with every increment in dose during first stage of labor and every 5 minutes in second stage of labor. Report changes in vital signs and FHR, specifically late decelerations and any vaginal bleeding.

Ergot Alkaloids

The **ergot alkaloids** (one of a large group of alkaloids derived from a fungus) act by direct smooth-muscle-cell receptor stimulation. These drugs are not used during labor, because they can cause sustained uterine contractions (tetanic contractions), which would result in fetal hypoxia and possibly rupture of the uterus. The uterus becomes more sensitive to these drugs too. After delivery, however, sustained contractions are effective in the prevention or control of postpartum hemorrhage and the promotion of uterine involution.

The most commonly used ergot derivative is methylergonovine maleate (Methergine). Methylergonovine maleate can be given by mouth but is most frequently administered by the IM route. IV administration is not recommended and is given only in emergency situations. If methylergonovine maleate is given IV, administer 0.2 mg over 1 minute. Transient significant elevations in BP can occur, particularly after IV infusion. Patients with gestational hypertension, hypertension, or peripheral vascular diseases should not receive ergot derivatives. Table 54-6 lists commonly used uterotonic drugs and their dosages, uses, and considerations.

Side Effects and Adverse Reactions

Side effects of ergot alkaloids include uterine cramping, nausea and vomiting, dizziness, hypertension with IV administration, sweating, tinnitus, chest pain, dyspnea, itching, and sudden severe headache. Signs of ergot toxicity (**ergotism**) include pain in arms, legs, and lower back; numbness; cold hands and feet; muscular weakness; diarrhea; hallucinations; seizures; and blood hypercoagulability.

Nursing Process
Patient-Centered Collaborative Care

Other Oxytocics: Ergonovine and Methylergonovine

Assessment

- Assess lochia and uterine tone before giving ergonovine or methylergonovine.
- Assess effectiveness of uterine massage and oxytocin administration on local flow and uterine tone.
- Recognize that these two drugs have a vasoconstrictive effect, which may cause hypertension. Ergonovine is more vasoconstrictive than methylergonovine.
- Obtain baseline BP before administration.

Nursing Interventions

- Monitor patient's BP per agency protocol.
- Protect drugs from exposure to light.
- Monitor for side effects or symptoms of ergot toxicity (ergotism). Notify health care provider if systolic BP increases by 25 mm Hg or diastolic BP by 20 mm Hg over baseline.

Patient Teaching

- Advise patient that she will feel more intense uterine cramps after receiving drug but may receive analgesics for pain.
- Encourage patient to avoid smoking. Nicotine increases vasoconstrictive properties of these drugs.

Side Effects

- If patient is breastfeeding, explain that drug lowers serum prolactin levels with potential to inhibit postpartum lactation. Ergonovine has greater potential to inhibit lactation than methylergonovine.

Cultural Considerations

- Recognize cultural influence on patient's expression or lack of expression of discomfort and/or pain.
- Provide an interpreter as appropriate.

Evaluation

- Evaluate effectiveness of drug by assessment of lochia and uterine tone. Count and weigh perineal pads as appropriate.
- Continue monitoring maternal vital signs, specifically pulse and BP. Report changes in maternal vital signs, continued excessive vaginal bleeding, or uterine atony.

SURFACTANT THERAPY IN PRETERM BIRTH

Synthetic Surfactant

One approach to respiratory difficulties in the preterm infant is surfactant replacement therapy. This is used to prevent the

TABLE 54-6 UTEROTONIC DRUGS COMMONLY USED TO ENHANCE UTERINE CONTRACTILITY

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
oxytocin (Pitocin)	See Prototype Drug Chart 54-1.	
15 methyl prostaglandin F_2-alpha or carboprost tromethamine (Hemabate)	0.25 mg as IM with repeat injections every 15-90 min as needed; 4 doses can be given if hypertension is present	Prostaglandin. Direct stimulation of uterine smooth muscle. Treatment of postpartum hemorrhage secondary to uterine atony. IM: Onset: Unknown; Peak: 15-60 min; Duration 24 h. Maximum total dose: 2 mg. Give deep IM with tuberculin syringe. Contraindicated before delivery of placenta. Use with caution in patients with acute renal disease, cardiac disease, hypertension, inflammatory disease of female pelvic organs, and asthma. Adverse reactions: Diarrhea, nausea, vomiting, fever, abdominal pain with cramps. Pregnancy category: C; t½: UK.
methylergonovine maleate (Methergine)	PO: 0.2-0.4 mg, q6-12h; *max:* 1 wk IM: 0.2 mg after delivery of anterior shoulder (if full obstetric supervision), after delivery of placenta, or postpartum; repeat q2-4h; oral doses may follow parenteral IV: Same as for IM; but slowly over 1 min with careful monitoring of BP (IV route for acute emergencies only [e.g., bleeding])	Prevention and treatment of postpartum hemorrhage, subinvolution, and postabortion hemorrhage. Exhibits similar smooth-muscle action to ergotamine, but primarily affects smooth muscle, producing sustained contractions and shortening third stage of labor. IV: Onset: immediate; Duration: 45 min. IM: Onset: 2-5 min; Duration: 3 h. PO: Onset: 5-25 min; Duration: 3 h. Metabolized in liver; eliminated in urine. Not routinely administered IV because of possible sudden hypertensive and cerebrovascular accidents; limit use in patients with hypertension (especially IV). Contraindicated with maternal sepsis, labor induction, threatened spontaneous abortion; do not use with vasodepressors, other ergot alkaloids, or vasoconstrictors. Appears in breast milk, but interference with breastfeeding is less than with ergonovine. Adverse reactions: transient hypertension, diaphoresis, palpitations, dizziness, headache, nausea, vomiting, tinnitus, transient chest pain, dyspnea. Pregnancy category: C; PB: UK; t½: biphasic: initial: 1-5 min; terminal: 30 min-2 h

BP, Blood pressure; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *tab,* tablet; *UK,* unknown; *wk,* week.

development of **respiratory distress syndrome** (RDS) (respiratory disease of the newborn with absence, deficiency, or alteration in surfactant production). **Surfactant** (a lipoprotein in the alveoli that reduces surface tension of pulmonary fluids and keeps alveoli open during expiration) replacement therapy is also used to decrease the severity of RDS after diagnosis. Supplementing the amount of endogenous surfactant available to maintain distention of the alveolar sacs is the focus of this therapy.

The FDA has approved the use of beractant (Survanta), calfactant (Infasurf), and poractant alfa (Curosurf). Beractant lowers alveolar surface tension during respiration and stabilizes alveoli. Beractant intratracheal suspension, a natural bovine-lung extract, contains phospholipids, neutral lipids, fatty acids, and surfactant-associated proteins to which colfosceril palmitate (DPPC), palmitic acid, and tripalmitin are added. Beractant does not require reconstitution. Calfactant is a calf-lung surfactant that can be used preventilatory for prevention of RDS or postventilatory for treatment. Poractantalfa is porcine-lung surfactant and is indicated for rescue treatment. Each of these products defines prophylactic and rescue use differently and has different dosing and administration requirements. Table 54-7 lists the surfactant drugs used for prevention and treatment of RDS and their dosages, uses, and considerations.

All products require a patent endotracheal (ET) tube for administration and specified alterations in positioning the infant throughout the procedure to ensure even drug dispersion. These precise position changes allow gravity to assist in the distribution of the product in the lungs, particularly at the alveolar surface.

Rales and moist breath sounds may be a transient finding after administration of these products, particularly with beractant. Additionally, transient oxygen desaturation has occurred with poractant alfa, and airway obstruction has occurred in 39% of infants in clinical studies with calfactant. Unless obvious signs of airway obstruction are noted, suctioning should not be performed for 2 hours after administration.

Surfactant replacement therapy has been found effective in reducing the severity of RDS; rapid improvements in lung compliance and oxygenation may require immediate decreases in ventilator settings to prevent lung overdistention and pulmonary air leak.

TABLE 54-7 POSTNATAL SURFACTANT THERAPY FOR PREVENTION AND TREATMENT OF RESPIRATORY DISTRESS SYNDROME

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
beractant (Survanta) intratracheal suspension	4 mL/kg per dose ET (divide into 4 quarter doses and give each quarter dose with infant in different position) in one of two modes: Prophylaxis: 1 dose within 15 min of birth if possible; repeat in 6 h if respiratory distress continues; maximum 4 doses in 48 h (6 h apart). Rescue: 4 mL/kg intratracheally (also divide into 4 quarter doses and give each quarter dose with different infant positioning). Give dose as soon as RDS is diagnosed, preferably within 8 h of birth. Repeat in 6 h, giving a maximum of 4 doses in 48 h	Contains phospholipids, neutral lipids, fatty acids, and surfactant-associated proteins to which colfosceril palmitate (DPPC), palmitic acid, and tripalmitin are added. Each 1 mL contains 2.5 mg phospholipids. Must be given by health care personnel experienced with ventilators as prevention or rescue in treatment of RDS. Administered through a 5 French end-hole catheter as a dosing catheter inserted into ET tube. Following administration of each quarter dose, remove catheter from ET tube and ventilate infant for 30 sec until stable. Prophylaxis defined as use in infants less than 1250 g at high risk for RDS or larger infants with evidence of pulmonary immaturity. Rescue defined as treatment of infants with moderate to severe RDS. Biophysical effects occur at the alveolar surface; lowers surface tension on alveolar surfaces during respiration and stabilizes alveoli against collapse at resting pressures. Monitor infant's arterial or transcutaneous measurement of systemic oxygen or carbon dioxide. Drug should appear off-white to light brown. Swirl vial gently; DO NOT SHAKE. Some foaming is normal. Store at 36° to 46° F (2°-8° C); warm 20 min at room temperature or in hand for at least 8 min. Do not artificially warm. For prevention dose, begin preparation before infant's birth. Do not warm or return drug to refrigerator more than once. Adverse reactions: transient bradycardia, oxygen desaturation (associated with dosing procedure); ET tube reflux; ET blockage; pallor; vasoconstriction; hypotension; hypocarbia; hypercarbia; and apnea. All reactions resolve with symptomatic treatment See content below.*
calfactant (Infasurf)	3 mL/kg of birth weight as soon as possible after birth. Give as 2 doses of 1.5 mL/kg each every 12 h for total of 3 doses	Must be given by health care personnel experienced with ventilators and RDS. Stabilization of the premature infant with hypoxemia should occur before administration of calfactant therapy. Give preferably within 30 min after birth. Give through an ET tube. Draw dose with 20-gauge needle; avoid foaming. Gently agitate for dispersion of drug. Does not have to be warmed before administration. Refrigerate at 36°-46° F (2°-8° C). Adverse reactions: bradycardia, airway obstruction, apnea, hypoventilation, cyanosis, ET tube reflux, ET blockage. See content below.*
poractant alfa (Curosurf)	2.5 mL/kg of birth weight. Up to 2 additional doses of 1.25 mL/kg birth weight can be every 12 h; maximum dose 5 mL/kg	Administered via 5 French catheter inserted into ET tube. With infant positioned either right or left side dependent, administer one half dose into each main bronchus. Must be given by health care personnel experienced with ventilators and RDS. Do not suction airways for 1 h after surfactant instillation unless airway obstruction occurs. Multiple-dose regimen has evidenced efficacy. Reduce ventilator inspiratory pressures immediately if chest expansion improves substantially after dosing. Contraindications are previous hypersensitivity to any component of poractant alfa formulations. Adverse reactions: increased incidence of patent ductus arteriosus, hypotension, transient oxygen desaturation, apnea, and flushing
*beractant (Survanta) intratracheal suspension and calfactant (Infasurf)		Does not require reconstitution. Do not dilute or shake. Protect from light. No known contraindications.

ET, Endotracheal; *h,* hour; *min,* minute; *RDS,* respiratory distress syndrome; *sec,* second.

SAFETY: Preventing Medication Errors

Do not confuse …

- **fentanyl citrate** (Sublimaze) used as an adjunct to general or regional anesthesia, or for postoperative, persistent, moderate to severe pain, with **sufentanil** (Sufenta), used to induce anesthesia in combination with other drugs or as the sole anesthetic agent.

Adverse Reactions

Side effects during administration have included incidents of reflux of product up the ET tube with decreases in oxygenation. Dosing is slowed or halted if the infant (1) becomes dusky colored, (2) becomes agitated, (3) experiences transient bradycardia, (4) has oxygen saturation increases of more than 95%, (5) experiences improved chest expansion, or (6) has arterial or transcutaneous CO_2 levels <30 mm Hg. Pulmonary hemorrhage has been seen in infants treated with Exosurf. Suctioning before dosing decreases the chance for ET tube blockage during dosing. No long-term complications or sequela of synthetic surfactant therapy have been reported.

Nursing Process
Patient-Centered Collaborative Care
Beractant, Calfactant, and Poractant Alfa

Assessment

- Assess for informed consent. Separate consents are needed for multifetal birth.
- Assess infant's vital signs.

Nursing Diagnosis

- Impaired gas exchange related to inadequate lung surfactant secondary to fetal immaturity

Planning

- Infant's oxygen requirement and respiratory effort will decrease.
- Infant's need for mechanical ventilation will be quickly reduced.
- Infant will experience no respiratory distress within 1 hour of surfactant administration.

Nursing Interventions

Beractant Intratracheal Suspension

- Prepare drug with adequate time for drug to warm to room temperature for 20 minutes or in hand for at least 8 minutes. Do not artificially warm drug.
- Do not shake drug.
- Provide only off-white to light-brown product for use in procedure.
- Assist with positioning of infant after each quarter dose as detailed in protocol.

Calfactant

- Avoid excessive foaming.
- Draw up dose using 20-gauge or larger needle.
- Administer through side port of ET tube.
- Administer medication with infant on one-for-one dose, and turn to opposite side for subsequent dose.
- Administer while ventilation is continued over 20 to 30 breaths for each dose, with small bursts during inspiratory cycles.

Beractant Intratracheal Suspension and Calfactant

- Monitor infant carefully for chest expansion, color, arterial blood gases, oxygen saturation, heart rate, facial expression, ET tube patency, BP, and electrocardiogram.
- Monitor ventilator pressure readings and breath sounds.
- Expect infant's lungs to sound wet after administration; do not suction through endotracheal tube for 2 hours.

Poractant Alfa

- Draw up doses using 20-gauge or larger needle.
- Suction before dosing.
- Mucous plugging of ET tube can occur during or after dosing.
- Do not suction airways for 1 hour after surfactant instillation unless signs of airway obstruction present.
- Monitor ventilator inspiratory pressures, which should be reduced immediately if chest expansion improves after dosing administration.

Patient Teaching

General

- Explain to parents what respiratory distress syndrome is and how surfactant helps neonate.
- Explain to parents the purpose of multiple monitoring devices to reduce unrealistic fears about the neonate's condition.
- Ensure informed consent for usage.

Side Effects

- Encourage parents to verbalize understanding about risks associated with use of drug.

Evaluation

- Evaluate preadministration breath sounds and ventilator pressure readings to compare with postadministration findings.

KEY WEBSITES

National Center for Alternative and Complementary Medicine: *nccam.nih.gov*

Clinical Trials: Pregnancy Complications: *clinicaltrials.gov/ct/*

CRITICAL THINKING CASE STUDY

TA (gravida 3, para 0) is at 42 weeks' gestation. At her prenatal visit, her health care provider notes signs and symptoms of pregnancy-induced hypertension and advises TA about a plan to induce labor after administration of prostaglandin gel. TA asks the nurse, "Can you help me understand all of this?"

1. What objective tool (scoring system) can be used to predict the extent to which TA's cervix is "ripe" and therefore favorable for successful induction?

   TA's health care provider orders dinoprostone cervical gel for use in the cervix.
2. What will be accomplished with use of the gel?
3. Who will administer the gel?
4. How often can the gel be administered?
5. How long after the last dose of gel can the IV oxytocic medication be started to induce labor?
6. Why is there a waiting period before starting the oxytocin?
7. Further questioning reveals that TA has been ingesting a pregnancy tonic that includes herbal supplements since she was 36 weeks' gestation. List three concerns specific to pregnancy.

   It is 16 hours since TA first had the gel inserted. Responding to TA's call light, the nurse finds TA in the bathroom, upset because she feels nauseous and is occasionally vomiting a little stomach fluid, and complaining that her stool is watery. "Is something wrong?" TA asks.
8. Analysis of the data about TA's symptoms supports what conclusion?
9. What nursing actions might be taken to support TA?
10. When TA returns to bed and the external fetal monitor is reapplied, what data should the nurse collect, record, and report to the obstetric provider?

It is 24 hours since TA had the first gel instillation and 6 hours since her last insertion. A vaginal examination reveals that TA's cervix is soft, 50% effaced, and 3 cm dilated, and that the presenting part is at 2 station. Contractions are 5 minutes apart and mild. The health care provider elects to begin an oxytocin infusion.

11. TA asks how "a medicine running into my arm is able to make my uterus contract." How should the nurse explain the mode of action of oxytocin to TA?
12. Why is the oxytocin infusion run through a secondary line attached as a "piggyback" to the primary line? At which port along the primary line is the piggyback inserted, and why?
13. Why is oxytocin administered via infusion pump? What is the measurement for dosing?
14. What actions in regard to IV equipment setup should be taken as safety measures before starting the oxytocin?
15. What drugs should be nearby in the event of an emergency with the oxytocin?
16. What information should be recorded during the infusion?
17. While setting up the oxytocin infusion, a new nurse being precepted to labor and delivery asks what criteria is used to know when to slow the rate or stop the infusion. The nurse correctly responds that contractions would be _____ minutes apart with _____ intensity, and the cervix would be dilated at least _____ cm.
18. If uterine hyperstimulation occurs, explain how to handle the situation. Address the following:

    Position TA; rationale: ___________________________

    IV fluids; rationale: ___________________________

    Oxygen; rationale: ___________________________
19. TA asks what side effects can occur if she receives a continuous lumbar epidural. What is the appropriate response?

NCLEX STUDY QUESTIONS

1. A patient, gravida 3, para 2, and 40.6 weeks' gestation, asks, "Is there anything we can do to start labor besides medication? I'm so ready to have this baby." What is the nurse's best response?
   a. "No, there is nothing we can do until you go into labor."
   b. "Amniocentesis should be done to be sure the lungs are mature before we start labor."
   c. "Some women have sex or ride in a car on a bumpy road to start labor."
   d. "Some health care providers may place a balloon catheter or strip the membranes if the cervix is ripe."
2. A patient is to receive 10 mg nalbuphine slow IV push for pain relief during labor. When will the nurse plan to administer nalbuphine?
   a. During the uterine contraction
   b. At the end of the uterine contraction
   c. Between uterine contractions
   d. At any time during the contractions

3. A patient received butorphanol 2 mg IV 10 minutes immediately before delivery. Which of these is important nursing care for this patient?
   - a. Subcutaneous administration
   - b. Having naloxone (Narcan) available
   - c. Fluid bolus IV to the mother
   - d. Oxygen 10 L by nasal cannula to the mother
4. A patient is to have lumbar epidural anesthesia. Based on this health care provider order, what would the nurse prepare to administer?
   - a. citric acid/sodium citrate (Bicitra)
   - b. promethazine (Phenergan)
   - c. A bolus of 500 to 1000 mL of a crystalloid IV solution
   - d. Rh$_{O}$(D) immune globulin (RhoGAM) injection
5. A 33-year-old patient in active labor is experiencing "back labor" with intense pain in her lower back. What is the most effective nursing intervention?
   - a. Counterpressure against the sacrum
   - b. Pant-blow breathing techniques
   - c. Effleurage
   - d. Conscious relaxation or guided imagery
6. A patient has an epidural for pain control during labor. During the assessment, the nurse notes a drop in the patient's BP. What is the priority nursing intervention?
   - a. Administer low-flow oxygen.
   - b. Turn her on her left side.
   - c. Assess her urinary output.
   - d. Monitor her vaginal bleeding.
7. A patient is to have a stat cesarean section due to late fetal decelerations. Before surgery, the nurse administers citric acid/sodium citrate (Bicitra). What patient response would indicate effective patient teaching regarding citric acid/sodium citrate?
   - a. "Citric acid/sodium citrate will prevent infection after the cesarean section."
   - b. "The medication will neutralize the contents in my stomach."
   - c. "The citric acid/sodium citrate will reduce the need to use pain medication after the cesarean section."
   - d. "This medication is administered to prevent vomiting after the cesarean section."
8. Spinal anesthesia with morphine (Duramorph) is administered to a patient for pain relief during cesarean section. The patient complains of itching. The nurse prepares to administer which medication?
   - a. diphenhydramine
   - b. ephedrine sulfate
   - c. butorphanol tartrate
   - d. lidocaine (Xylocaine)
9. A nurse administered beractant (Survanta) to a premature infant to prevent respiratory distress syndrome. In assessing the infant's lungs, the nurse auscultated rales and moist breath sounds. What is the priority nursing intervention?
   - a. Notify the health care provider.
   - b. Suction immediately to remove the beractant.
   - c. Turn the infant "back to sleep."
   - d. Document the finding; this is a normal transient finding.
10. A patient is gravida 2, para 1 and is admitted to labor and delivery at 39.6 weeks' gestation in active labor. The health care provider performs an amniotomy. What is the nurse's priority intervention?
    - a. Monitor uterine contraction frequency and intensity
    - b. Check fetal heart rate
    - c. Assess for cervical dilation and effacement
    - d. Check for umbilical cord compression
11. A patient in labor is to have an epidural administered. Which nursing interventions should the nurse perform before the epidural is administered? (Select all that apply.)
    - a. Infuse 500 to 1000 mL of the ordered IV.
    - b. Check maternal blood pressure.
    - c. Assess fetal heart rate.
    - d. Have patient empty her bladder.
    - e. Position patient in lithotomy position.
    - f. Administer 2 L/min of oxygen via nasal cannula.

Answers: 1, d; 2, a; 3, b; 4, c; 5, a; 6, b; 7, b; 8, a; 9, d; 10, b; 11, a, b, c, d.

OBJECTIVES

- Discuss the purpose, action, side effects, and nursing implications of the drugs commonly administered during the postpartum period.
- Discuss the purpose, action, side effects, and nursing implications of the drugs administered to the newborn.
- Describe the nursing process, including patient teaching, related to drugs used during the postpartum period and drugs administered to the newborn immediately after delivery.

OUTLINE

Drugs Used during the Postpartum Period
- Pain Relief for Uterine Contractions
- Pain Relief for Perineal Wounds and Hemorrhoids
- Nursing Process: Patient-Centered Collaborative Care: Pain Relief for Perineal Wounds and Hemorrhoids
- Lactation Suppression
- Promotion of Bowel Function
- Nursing Process: Patient-Centered Collaborative Care: Laxatives

Immunizations
- $Rh_O(D)$ Immune Globulin
- Nursing Process: Patient-Centered Collaborative Care: $Rh_O(D)$ Immune Globulin
- Rubella Vaccine
- Nursing Process: Patient-Centered Collaborative Care: Measles-Mumps-Rubella Vaccine

Drugs Administered to the Newborn Immediately after Delivery
- Nursing Process: Patient-Centered Collaborative Care: Drugs Administered to the Newborn after Delivery
- Immunization during the Newborn Period before Discharge
- Nursing Process: Patient-Centered Collaborative Care: Hepatitis B Vaccine

This chapter focuses on pharmacologic considerations for mothers and infants after delivery. Nonpharmacologic measures and pharmacologic agents related to the relief of common maternal discomforts during the postpartum period are also described. In addition, drugs commonly administered to newborns immediately after delivery are discussed.

DRUGS USED DURING THE POSTPARTUM PERIOD

During the **puerperium** (the period from delivery until 6 weeks postpartum), the maternal body physically recovers from antepartal and intrapartal stressors and returns to its prepregnant state.

Pharmacologic and nonpharmacologic measures commonly used during the postpartum period have five primary purposes: (1) to prevent uterine atony and postpartum hemorrhage; (2) to relieve pain from uterine contractions, perineal wounds, and hemorrhoids; (3) to enhance or suppress **lactation** (production and release of milk by mammary glands); (4) to promote bowel function; and (5) to enhance immunity (Box 55-1).

Whenever possible, nonpharmacologic measures are preferred to the use of drugs or are used in conjunction with drugs (Herbal Alert 55-1). Postpartum nursing care ideally occurs as a partnership between the nurse and the new family. To enhance health and wellness, the nurse collaborates with the mother and family to strengthen the new mother's self-confidence and ability to handle her own health challenges. The nurse's role in this system is threefold:

- To assess and discuss postpartal physical changes and pain management with the patient and determine both healing progress within a standard and effectiveness of medications
- To teach the patient and administer postpartal medications
- To teach the patient and administer narcotic analgesics (as prescribed) when pain control by nonnarcotic products is ineffective.

BOX 55-1 ROUTINE POSTPARTUM MEDICATION ORDERS

Vaginal Delivery Postpartum Medications

Standing Orders

oxytocin (Pitocin) 20 units in 1 L D$_5$LR or 10 units IM
ferrous sulfate (FeSO$_4$) 325 mg PO b.i.d/t.i.d.
Prenatal vitamin 1 tab PO daily
Motrin 800 mg t.i.d

PRN Orders

docusate sodium (Colace) 100 mg PO b.i.d. PRN for constipation OR
Dulcolax suppository PR PRN for constipation
Lanolin PRN if breastfeeding
Measles-mumps-rubella vaccine if not immunized

Cesarean Birth Postpartum Medications

Standing Orders

cefazolin (Ancef) 1 gram IVPB × 1 dose at time of cesarean section
oxytocin (Pitocin) 20 units in 1 L D$_5$LR or 10 units IM
POD 1
ferrous sulfate (FeSO$_4$) 325 mg PO b.i.d./t.i.d.
Prenatal vitamin 1 tab PO daily
Motrin 800 mg t.i.d

PRN Orders

POD 1
- nalbuphine 5-10 mg subQ or IV q2-3h OR
- meperidine (Demerol) 50-75 mg IM q3-4h PRN for pain
- acetaminophen/codeine (Tylenol No. 3) 1-2 tab PO q3-4h PRN for pain OR
- oxycodone/acetaminophen (Percocet) 1 tab PO q6h PRN for pain
- hydroxyzine (Vistaril) 25-50 mg IM q3-4h PRN for nausea
- prochlorperazine (Compazine) 10 mg IV q4-6h PRN for nausea OR
- promethazine (Phenergan) 25-50 mg IV q3-4 h PRN for nausea
- A & D cream or Lanolin PRN if breastfeeding

POD 2
- bisacodyl (Dulcolax) suppository PR PRN for constipation OR
- magnesium hydroxide (milk of magnesia) 30 mL PO q6h PRN
- simethicone (Gas-X) 80 mg PO q.i.d. PRN for bloating and/or gas
- Rubella vaccine (Meruvax II) subQ if not immunized

b.i.d., Twice a day; *h,* hour; *IM,* intramuscular; *IVPB,* intravenous piggyback; *PO,* by mouth; *PRN,* as needed; *q.i.d.,* four times a day; *subQ,* subcutaneous; *tab,* tablet; *t.i.d.,* three times a day.

HERBAL ALERT 55-1

Use of Herbs during Lactation

Because little is known about the safety of herbal supplements, they are not generally recommended during lactation. Breastfeeding patients should be advised to check with their health care provider before taking any herbal supplements; those contraindicated for breastfeeding patients include aloe, belladonna, black tea, bromelain, buckthorn bark, burdock, cat's claw, chondroitin, comfrey, echinachea, ephedra/ma-huang, eucalyptus, flaxseed, kava kava, lavender, licorice, milk thistle, pennyroyal, and saw palmetto. This list is not exhaustive; for more information, refer to Chapter 6.

Pain Relief for Uterine Contractions

"Afterbirth pains" may occur during the first few days postpartum when uterine tissue experiences ischemia during contractions, particularly in multiparous patients and when breastfeeding. Nonsteroidal agents may be used to control postpartal discomfort and pain, with narcotic agents reserved for more severe pain such as that experienced by the patient after cesarean delivery, tubal ligation, or extensive perineal laceration. Box 55-2 lists systemic analgesics commonly used during the postpartum period.

Because some systemic analgesics (e.g., codeine, meperidine) can cause decreased alertness, it is important for the nurse to observe the patient as she cares for her newborn to ensure safety. Patients who receive opioids, such as morphine sulfate or codeine sulfate, should be assessed for bowel function and respirations. With continued opioid use, patient assessment of bowel history is necessary, because these drugs

BOX 55-2 COMMONLY USED POSTPARTUM SYSTEMIC ANALGESICS

acetaminophen (Tylenol)
acetaminophen/codeine (Tylenol No. 3)
acetaminophen and propoxyphene
ibuprofen (Motrin)
codeine sulfate
ketorolac tromethamine (Toradol)
acetaminophen and hydrocodone (Lortab)
meperidine (Demerol)
morphine sulfate
nalbuphine oxycodone acetaminophen (Percocet)

can exacerbate the constipation of pregnancy. During the intrapartum period, women are NPO (nothing by mouth) or ingest limited liquids and are not ambulatory, all factors that contribute to decreased bowel activity. In addition, respiratory assessment is important for patients receiving opioids, because respiratory depression may occur. Frequently nonsteroidal agents like ibuprofen and ketorolac tromethamine are used to control postpartum discomfort and pain. Nonsteroidal antiinflammatory drugs (NSAIDs) inhibit the enzyme cyclooxygenase (COX), of which there are two isoenzymes, COX-1 or COX-2; both decrease prostaglandin synthesis. These drugs are effective in relieving mild to moderate pain caused by postpartum uterine contractions, episiotomy, hemorrhoids, and perineal wounds. NSAIDs commonly cause gastrointestinal (GI) irritation, and it is recommended that patients take them with a full glass of water or with food to minimize GI distress. With administration of NSAIDs, a lower narcotic dosage may control pain as a result of the additive analgesic effect. The use of NSAIDs requires ongoing assessment for GI bleeding. These drugs inhibit platelet synthesis and may prolong bleeding time. Patient teaching with this category of drugs is important, because some NSAIDs may be purchased over the counter (OTC). Patient teaching includes avoidance of these drugs while pregnant if symptoms of GI bleeding occur (dark, tarry stools; blood in urine; coffee-ground emesis) and avoidance of the concurrent use of alcohol, aspirin, and corticosteroids, which may increase the risk for GI toxicity.

Pain Relief for Perineal Wounds and Hemorrhoids

Pregnancy and the delivery process increase the pressure on perineal soft tissue. The tissue may become ecchymotic or edematous. Increased edema, ecchymosis, and pain may occur if an **episiotomy** (incision made to enlarge the vaginal opening to facilitate newborn delivery) or perineal laceration is present. The perineum is assessed for *R*edness, *E*cchymosis, *E*dema, *D*ischarge, and *A*pproximation (REEDA). In addition, hemorrhoids that developed during pregnancy may be exacerbated by the pushing during labor. Comfort measures (ice packs immediately after birth, tightening of the buttocks before sitting, use of peribottles and cool or warm sitz baths) and selected topical agents (witch hazel and dibucaine ointment) may relieve pain and minimize discomfort (Table 55-1). Note that rectal suppositories should not be used by women with fourth-degree perineal lacerations.

Side Effects and Adverse Reactions

The most commonly reported side effects of topical or local agents include burning, stinging, tenderness, edema, rash, tissue irritation, sloughing, and tissue **necrosis** (death of tissue caused by disease or injury). The most commonly reported side effects of hydrocortisone local or topical drugs include burning, pruritus, irritation, dryness, **folliculitis** (skin inflammation resulting from contact with an irritating substance or allergen), allergic contact dermatitis, and secondary infection. These side effects are more likely to occur when **occlusive** (i.e., obstructive) dressings are used.

Nursing Process

Patient-Centered Collaborative Care

Pain Relief for Perineal Wounds and Hemorrhoids

Assessment

- Assess patient's cultural framework for health.
- Assess patient's pain using agency pain scale. Assess perineal area for wounds and hemorrhoids (size, color, location, pain scale, REEDA).
- Check expiration dates on topical spray cans, bottles, and ointment tubes.
- Assess for presence of infection at perineal site; avoid use of benzocaine on infected perineal tissue.

Nursing Diagnoses

- Deficient knowledge of causes of pain and discomfort; inexperience with treatment measures, nonpharmacologic and pharmacologic
- Acute pain related to episiotomy, perineal laceration, or hemorrhoids

Planning

- Patient's perineal discomfort will be alleviated by use of topical sprays, compresses, sitz baths, and ointment.

Nursing Interventions

- Teach patient about use of peribottle. Use warm water and direct water on perineum from front to back (clean to dirty).
- Do not use benzocaine spray when perineal infection is present.
- Shake benzocaine spray can. Administer 6 to 12 inches from perineum with patient lying on her side with top leg up and forward to provide maximum exposure. This can also be done with one foot on the toilet seat.

TABLE 55-1 DRUGS USED TO RELIEVE PAIN FROM PERINEAL WOUNDS AND HEMORRHOIDS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Perineal Wounds (Episiotomy or Laceration)		
benzocaine (Americaine, Dermoplast)	Spray liberally t.i.d./q.i.d. 6-12 inches from perineum following perineal cleansing Supplied as aerosol benzocaine 20%	Local anesthetic; inhibits impulses from sensory nerves by decreasing permeability of cell membrane to sodium ions. Apply 6-12 inches from affected area. Peak: 1 min; duration: 30-60 min. Hydrolyzed in plasma and liver (to lesser extent) by cholinesterase; eliminated as metabolites in urine. Well absorbed from mucous membranes and traumatized skin. Contraindicated in patients with secondary bacterial infection of tissue and known hypersensitivity
witch hazel pads (Tucks [50% witch hazel with glycerin, water, and methylparaben]) (may also be used for hemorrhoids)	Apply premoistened pads t.i.d./q.i.d. to wound site	Precipitates protein, causing tissue to contract. May be chilled/refrigerated in original container for additional comfort. If liquid, pour over ice and dip absorbent pads into solution; change when diluted. Medical intervention should be sought if rectal bleeding is present. Side effect: local irritation (discontinue use)
Hemorrhoids		
hydrocortisone acetate 10 mg (Anusol-HC, Tucks Ointment [pramoxine HCl 1%, mineral oil 46.7%, zinc oxide 12.5%])	1 suppository b.i.d. for 3-6 d	Relieves pain and itching from irritated anorectal tissue. Anusol-HC contains hydrocortisone acetate, acts as an antiinflammatory agent. Available without hydrocortisone. Wear gloves. Onset: UK; Peak: UK; Duration: UK. Contraindicated in patients with known hypersensitivity. Discontinue if second infection in tissue. If anorectal symptoms do not improve in 7 days or if bleeding, protrusion, or seepage occurs, inform health care provider. Do not use if fourth-degree perineal laceration present. Not known if excreted in breast milk; use cautiously. Pregnancy category: C
hydrocortisone acetate 1% and pramoxine HCl 1% topical aerosol (Proctofoam-HC)	1 applicator transferred to 2-by-2–inch pad and placed against rectum inside peri-pad b.i.d./t.i.d. and after bowel movements	Topical corticosteroid aerosol foam with same action and considerations as above. Also available in nonsteroidal preparation. Shake foam aerosol before use. Onset: UK; Peak: UK; Duration: UK. Extent of percutaneous absorption of topical corticosteroids determined by vehicle integrity, epidermal barrier, and use of occlusive dressings. Not known if any quantity detectable in breast milk. Side effects: burning, itching, irritation; dryness, infrequent folliculitis reactions
dibucaine ointment, USP 1% (Nupercaine)	Apply as above t.i.d./q.i.d., using no more than 1 tube in 24 h	Local anesthetic ointment containing dibucaine 1%. Action same as benzocaine. Onset: within 15 min; Peak: UK; Duration: 2-4 hours. Do not use if rectal bleeding present. Do not use near eyes or over denuded surfaces or blistered areas. Do not use if known hypersensitivity to amide-type anesthetics. Side effects: burning, tenderness, irritation, inflammation, contact dermatitis, urticaria, cutaneous lesions, edema. Pregnancy category: C

b.i.d., Two times a day; *d,* day; *h,* hour; *min,* minute; *q.i.d.,* four times a day; *t.i.d.,* three times a day; *UK,* unknown.

- Use witch hazel compresses (glycerin and witch hazel [Tucks] or witch hazel solution) with an ice pack and a peri-pad to apply cold to the affected area in addition to the active agent.
- Store pramoxine and zinc oxide topical (Anusol) or hydrocortisone acetate (Anusol-HC) suppositories below 86° F (30° C), but protect them from freezing. Use gloves for administration. If patient is breastfeeding, assess to determine whether patient is ready to switch to preparation without hydrocortisone (goal is to discontinue use of suppositories as quickly as possible).
- Check lot numbers and expiration dates.
- Use of pramoxine HCl (Proctofoam-HC) must be explained carefully, because directions instruct patient to place agent inside the anus, which is not generally done with obstetric patients (they may have perineal wounds that extend into the anus). Rectal suppositories should not be used by patients with fourth-degree perineal laceration.

Patient Teaching

General

- Describe the process of perineal wound healing.
- Explain expected action and side effects. With witch hazel a cooling, soothing sensation will provide relief.

Ointment and suppositories will soothe, lubricate, and coat mucous membranes. Pramoxine HCl is not chemically related to "-caine"-type local anesthetics, and there is a decreased chance of cross-sensitivity reactions in patients who are allergic to other local anesthetics.

- Advise patient that drug is not for prolonged use (no more than 7 days) or for application to a large area.
- Explain that topical analgesia lasts for several hours after use.
- Advise patient to store suppositories below 86° F (30° C) so suppositories do not melt but do not freeze. Counsel patient with bleeding hemorrhoids to use drug carefully and to keep health care provider informed if condition exacerbates or does not improve within 7 days.

Self-Administration: Perineal Wounds: Topical Spray Containing Benzocaine

- Apply three to four times daily or as directed.
- Apply without touching sensitive area.
- Hold can 6 to 12 inches from affected area. Administer spray by either lying on side in bed while spraying from behind or by standing with one foot on chair or toilet seat.
- Assess use of complementary and alternative medicines, including herbal supplements.
- Avoid contact of medication with eyes.
- Teach patient not to use perineal heat lamp after application, because this could cause tissue burns.
- If condition exacerbates or symptoms recur within a few days, notify health care provider and discontinue use until directed.
- Keep medication out of children's reach in postpartum unit and later at home. If ingested, contact poison control center immediately.
- Store below 120° F (49° C). Dispose of empty can without puncturing or incinerating.

Self-Administration: Hemorrhoids and Perineal Wounds: Witch Hazel Compresses

- Pour liquid witch hazel over chipped ice; place soft, clean, absorbent squares in solution; squeeze square to eliminate excess moisture; fold and place moist square against episiotomy site or hemorrhoids.
- If using commercial medicated pads, entire container may be placed in refrigerator.
- Avoid touching surface of pad placed next to perineal wound.
- Teach patient when to change compress and how to place ice bag and peri-pad over compress.
- Do not insert medicated pads into rectum.
- Keep product out of children's reach.
- Do not use if rectal bleeding present.
- Discontinue use if local irritation occurs.

Self-Administration: Hemorrhoids: Tucks Ointment and Tucks Suppositories

- Apply ointment externally in postpartum period.
- Place suppository in lower portion of anal canal. Caution: products usually are not inserted rectally if fourth-degree lacerations are present.
- Apply small quantity of ointment onto 2-by-2–inch gauze pad; place inside peri-pad against swollen anorectal tissue approximately 5 times per day.
- If suppository is ordered, tell patient to keep refrigerated but not frozen. Remove wrapper before inserting in rectum (hold suppository upright, and peel evenly down sides). Do not hold suppository for prolonged period, because it will melt. If suppository softens before use, hold in foil wrapper under cold water for 2 to 3 minutes.
- Ascertain patient hypersensitivity to any components of ointment (e.g., pramoxine HCl 1%, mineral oil 46.7%, zinc oxide 12.5%).
- Avoid contact of medication with eyes.
- Ointment may occasionally cause burning sensation in some patients, especially if anal tissue is not intact.
- If erythema, irritation, edema, or pain develops or increases, discontinue use and consult health care provider.
- Notify health care provider if bleeding occurs.

Self-Administration: Hydrocortisone and Pramoxine and Pramoxine HCl

- Advise patient that product is for anal or perianal use only and is not to be inserted into rectum.
- Shake can vigorously before use.
- Fully extend applicator plunger; hold can upright to fill applicator.
- Express contents of applicator onto a 2-by-2–inch gauze pad, and place inside peri-pad against rectum.
- Use two to three times daily and after bowel movements.
- Take applicator apart after each use, and wash with warm water.
- Keep aerosol container out of children's reach in postpartum unit and later at home.
- Store below 120° F (49° C).
- Dispose of aerosol container without puncturing or incinerating.
- Avoid contact of medication with eyes.
- Advise patient that it is not known if topical administration of corticosteroids results in sufficient systemic absorption to produce detectable quantities in breast milk. Burning, itching, irritation, dryness, and folliculitis may occur, especially if occlusive dressings are used.

Self-Administration: Dibucaine Ointment 1%

- Express ointment from applicator on a tissue or 2-by-2–inch gauze pad, and place against the anus. Do not insert applicator into rectum. Effects should be within 15 minutes and last for 2 to 4 hours. Ointment is poorly absorbed through intact skin, but it is well absorbed through mucous membranes and excoriated skin.

- Do not use product near eyes, over denuded surface or blistered areas, or if there is rectal bleeding.
- Do not use more than one tube (30-g size) in 24 hours.
- Keep medication out of children's reach.
- Ask patient if there is any known hypersensitivity to amide-type anesthetics; if so, product is contraindicated.
- Local effects may include burning, tenderness, irritation, inflammation, and contact dermatitis; inform health care provider if these occur.
- Other side effects may include edema, cutaneous lesions, and urticaria.

Cultural Considerations

- Provide an interpreter with same ethnic background and gender if possible, especially with sensitive topics.

Evaluation

- Reevaluate patient's perception of pain after use of nonpharmacologic and pharmacologic measures. Identify need for additional patient teaching.
- Reassess perineal and anal tissues for integrity, healing, and any side effects.

Lactation Suppression

In the past, lactation was commonly controlled through drug therapy with one of three agents: chlorotrianisene (Tace), Deladumone OB (combination of estrogen plus androgen in the form of estradiol valerate and testosterone enanthate), or bromocriptine mesylate (Parlodel). Estrogenic substances are much less popular than in the past because of the increased incidence of thrombophlebitis associated with the high dosage needed to suppress lactation and concerns about potential carcinogenic effects. Although these drugs are not used now, your patients and their families may ask about these medications, which were given in the past for lactation suppression. Presently nonpharmacologic measures are recommended for lactation suppression, such as wearing a supportive bra 24 hours a day for 10 to 14 days or using axillary ice packs) (Table 55-2). Other strategies include taking 200 mg of pyrioxidine (vitamin B_6) for 5 days, ingesting sage tea approximately every 6 hours, using 3 to 4 mL of alcohol tincture every 6 hours via the mucous membranes, and applying pounded cold cabbage leaves to breasts and aerola, changing every 30 minutes as cabbage leaves wilt.

Promotion of Bowel Function

Constipation is common during the postpartum period. The residual effects of progesterone on smooth muscle decrease peristalsis. This decreased paristalsis, added to decreased liquid intake during labor, decreased activity, and relaxation of the abdominal muscles, amplifies the problem. Patients who deliver by cesarean section are even more likely to experience constipation and **flatus** (intestinal gas). Nonpharmacologic measures (e.g., high-fiber foods, early ambulation, drinking at least 64 ounces of fluids per day, promptly responding to the defecation urge) are generally instituted after delivery.

Pharmacologic measures include the use of stool softeners, laxative stimulants, and for the postcesarean patient, **antiflatulents** (used to treat excessive gas in the stomach and intestines) (Table 55-3).

Side Effects and Adverse Reactions

The following side effects have been reported:

- Docusate sodium (Colace): Bitter taste, throat irritation, rash
- Sennosides and docusate sodium (Peri-Colace): Nausea, abdominal cramping, diarrhea, rash
- Bisacodyl suppositories (Dulcolax): Proctitis and inflammation
- Magnesium hydroxide (milk of magnesia): Abdominal cramps, nausea
- Senna (Senokot): Nausea, vomiting, diarrhea, abdominal cramps; can also cause diarrhea in breastfed infants
- Mineral oil: Nausea, vomiting, diarrhea, abdominal cramps; if aspirated, lipid pneumonitis may occur

Nursing Process
Patient-Centered Collaborative Care

Laxatives

Assessment

- Note time of delivery, predelivery food and fluid intake, ambulation and activity, and predelivery bowel habits. Obtain history of bowel problems.
- Assess patient's bowel sounds in all four quadrants (particularly post–cesarean delivery), and note abdominal distention.
- Assess perineal area for wounds, hemorrhoids, and episiotomy (REEDA).

Nursing Diagnoses

- Risk for constipation related to perineal discomfort, decreased peristalsis, and use of opioids
- Fear of acute pain related to first postdelivery bowel movement secondary to episiotomy, hemorrhoids, or perineal wounds

Planning

- Patient will have bowel movement by 2 to 4 days postpartum.
- Patient will resume normal prepregnancy bowel elimination pattern within 4 to 6 weeks.

TABLE 55-2 NONPHARMACOLOGIC MEASURES FOR COMMON POSTPARTUM NEEDS

INDICATION	INTERVENTION
Uterine contractions	Patient positioned on abdomen with pillow under abdomen for 20-30 min for 3-4 d
	Distraction, breathing techniques, therapeutic touch, relaxation, guided imagery, ambulation
	No heat to abdomen because of risk of uterine relaxation and increased bleeding
Perineal wound resulting from episiotomy or laceration	Ice packs/glove (covered in thin, absorbent material to protect tissue) for 6-8 hours after delivery
	Patient positioned on side as much as possible with pillow between legs
	Early and frequent ambulation
	Perineal exercises (Kegel exercises)
	Cool sitz bath 2-3 h after delivery
	Warm sitz bath 12-24 h after delivery t.i.d./q.i.d.
	Area cleansed front to back using perispray squeeze bottle, cleansing shower, or Surgi-Gator
	Patient tightens buttocks or squeezes buttocks together before sitting and sits tall and flat, not rolled back onto coccyx
	No tampons, douche, or feminine hygiene sprays
	No intercourse until after lochia has ceased or as advised by health care provider
Hemorrhoids	As above but particularly:
	Ice
	Sims position to help increase venous return
	Warm, moist heat; sitz bath
	Witch hazel pads (e.g., Tucks)
Lactation suppression	Tight bra worn continuously for 10-14 days
	Normal fluid intake
	No manipulation or stimulation of breasts
	Pyrioxidine (B_6) 200 mg for 5 days
	Sage tea every 6 hours
	Alcohol tincture 3-4 mL every 6 hours
Engorgement	As above, plus ice to axillary area of breasts if bottle feeding, or apply warm compresses if breastfeeding
	Express small amount of colostrum or milk (if breastfeeding) by hand expression before putting infant to breast to facilitate latching on
Sore or cracked nipples	Wear absorbent breast pads to keep moisture away from nipples
	Do not use soap on nipples
	Air-dry nipples after nursing
	Express small amount of breast milk on nipples to use as a protective lubricant
	Apply hypoallergenic purified lanolin (Lansinoh, PureLan) to nipples as protective lubricant to promote healing
	For cracked nipples, use comfort gel pads (Hydrogel pads)
	Do not use nipple shields because they can promote chafing
	Do not limit infant's nursing time at breast; otherwise milk ducts will not be emptied, and increased pressure may occur
	Ensure proper positioning for feeding; nursing initiated on less sore nipple
	Break suction with little finger after feeding to prevent pulling on nipple

b.i.d., Twice a day; *d,* day; *h,* hour; *min,* minute; *NA,* not applicable; *PB,* protein-binding; *p.c.,* after meals; *PO,* by mouth; *q.i.d.,* four times a day; $t_{1/2}$, half-life; *t.i.d.,* three times a day; *UK,* unknown; *>,* greater than.

Nursing Interventions

- *Docusate Sodium and Sennosides with Docusate Sodium*
- Store at room temperature.
- If liquid preparation is ordered, give with milk or fruit juice to mask bitter taste.
- Take with full glass of water.
- Assess patient for history of laxative dependence.
- Drug interaction may occur with mineral oil, phenolphthalein, or aspirin.

Bisacodyl USP

- Store tablets and suppositories below 77° F (25° C), and avoid excess humidity.
- Do not crush tablets.
- Do not administer within 1 to 2 hours of milk or antacid, because enteric coating may dissolve, resulting in abdominal cramping and vomiting.
- Take with full glass of water.

Mineral Oil

- Do not give with or immediately after meals.
- Give with fruit juice or carbonated drink to disguise taste.

Magnesium Hydroxide

- Shake container well.
- Do not give 1 to 2 hours before or after oral drugs because of effects on absorption.
- Take with full glass of water.

TABLE 55-3 DRUGS USED TO PROMOTE POSTPARTUM BOWEL FUNCTION

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
docusate sodium (Colace) 550 mg with 3 mg sodium, 100-mg cap with 5 mg sodium (Dulcolax Stool Softener) 100 mg with 5 mg sodium docusate calcium (Surfak) 240-mg cap	100 mg PO b.i.d. 50-400 mg PO daily in 1-4 divided doses; usual dosage is 50-360 mg daily	Reduces surface tension of the oil-water interface of the stool, resulting in enhanced incorporation of water and fat and subsequent stool softening. Onset: 12-72 h. Docusate salts are interchangeable (amount of Na, Ca, or K per dosage is clinically insignificant). Do not use concomitantly with mineral oil. Contraindicated in patients with intestinal obstruction, acute abdominal pain, nausea, or vomiting. Do not use >1 wk. Prolonged, frequent, or excessive use may cause bowel dependence or electrolyte imbalance. Compatible with breastfeeding. Side effects: rash. Pregnancy category: C; PB: NA; t½: NA
sennosides with docusate sodium (Peri-Colace, Senokot); docusate sodium 50 mg; sennosides, 8.6 mg	1-2 tabs PO, usually h.s.	Mild stimulant laxative. Take with full glass of water. Onset: 8-12 h, but may require up to 24 h. Contraindicated in patients with abdominal pain, nausea, or vomiting. Compatible with breastfeeding. Adverse reactions: rash, abdominal cramping, diarrhea, nausea. Pregnancy category: C; PB: NA; t½: NA
bisacodyl USP (Dulcolax) (suppository 10 mg or tab 5 mg)	2-3 tabs PO or 1 supp, 5-15 mg/d given as single dose	Stimulant laxative. Irritates smooth muscle of intestine, possibly colon and intramural plexus; alters water and electrolyte secretion, increasing intestinal fluid and producing laxative effect. Onset PO: 6-10 h; rectally: 15 min-1 h. Absorption: 5% absorbed systemically following oral or rectal form. Metabolized in the liver to conjugated metabolites; excreted in breast milk, bile, and urine. Do not crush tabs (enteric coated). Do not administer within 1 h of milk or antacid, because enteric coating may dissolve, resulting in abdominal cramping and vomiting. Side effects: abdominal cramps, nausea, vomiting, rectal burning, electrolyte and fluid acidosis or alkalosis, hypocalcemia. Pregnancy category: C
magnesium hydroxide (milk of magnesia)	30 mL PO PRN daily or in divided doses	Laxative. Acts by increasing and retaining water in intestinal lumen, causing distention that stimulates peristalsis and bowel elimination. Onset: 4-8 h. Excreted in kidneys (absorbed portion); unabsorbed portion excreted in feces. Poses risk to patient with renal failure, because 15%-30% of magnesium is systemically absorbed. Use with caution in patients with impaired renal function, because hypermagnesemia and toxicity may occur as a result of decreased renal clearance of absorbed magnesium. Contraindicated in patients with colostomy, ileostomy, abdominal pain, nausea, vomiting, fecal impaction, and renal failure. Drug interactions may occur with tetracyclines, digoxin, indomethacin, iron salts, or isoniazid. Milk of magnesia concentrate is three times as potent as regular-strength product. Side effects: abdominal cramps, nausea. Adverse reactions: hypotension, hypermagnesemia, muscle weakness, and respiratory depression. Pregnancy category: B
magnesium hydroxide with mineral oil (Phillips MO)	30-60 mL PO daily	Mild saline laxative. Acts by drawing water into gut, increasing intraluminal pressure and intestinal motility. Onset: 0.5-6 hours. Pregnancy category: B. Equivalent to magnesium hydroxide
mineral oil	15-45 mL PO daily or in divided doses	Lubricant laxative eases passage of stool by decreasing water absorption and lubricating the intestine. Onset: 6-8 hours; Peak: UK; Duration: UK. May impair absorption of fat-soluble vitamins (A, D, E, K), oral contraceptives, coumarin, and sulfonamides. Avoid bedtime doses because of risk of aspiration (lipid pneumonitis). Do not give with food or meals because of risk of aspiration and decreased fat-soluble vitamin absorption. Contraindicated in patients with ileostomy, colostomy, appendicitis, ulcerative colitis, and diverticulitis. Best administered on an empty stomach. Side effects: nausea, vomiting, diarrhea, and abdominal cramps. Pregnancy category: C; PB: NA; t½: NA

Continued

TABLE 55-3 DRUGS USED TO PROMOTE POSTPARTUM BOWEL FUNCTION—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
senna (Senokot)	10-15 mL syrup h.s.; 2-4 tabs PO b.i.d	Stimulant laxative. Acts by local irritant effect on colon to promote peristalsis and bowel evacuation. Also increases moisture content of stool by accumulating fluids in intestine. Onset: 6-24 hours. Metabolized in liver; eliminated in feces (viable) and urine. Drug interactions may occur with (MAOIs, disulfiram, metronidazole, and procarbazine. May discolor urine or feces. Liquid syrup contains 7% alcohol. May create laxative dependence and loss of bowel function with prolonged use. Contraindicated in patients with fluid and electrolyte disturbances, abdominal pain, and nausea and vomiting. Excreted in breast milk. Pregnancy category: C; t½: NA
simethicone (Gas-X chewable tabs, 80 mg; Extra Strength Gas-X chewable tab, 125 mg; Gas-X Extra Strength softgel, 125 mg, Phazyme tab, 90 mg, cap, 125 mg, 180 mg; Mylanta Gas Relief chewable tab, 80 mg; Mylanta Gas Relief Maximum Strength chewable tab, 125 mg)	1 tab or softgel q.i.d. p.c. and h.s; *max:* 6 tabs or 4 softgels/24 h	Antiflatulent. Acts by dispersing and preventing formation of mucus-surrounded gas pockets in GI tract; changes surface tension of gas bubbles and allows them to coalesce, making them easier to eliminate as belching and rectal flatus. Must be chewed thoroughly before swallowing; suggest patient drink a full glass of water after tablets are chewed. Onset: UK. Excreted unchanged in feces. May interfere with results of guaiac tests of gastric aspirates. Do not take double doses to make up for missed doses. Store below 104° F (40° C) in well-closed container. No known side effects. Pregnancy category: C; t½: UK

b.i.d., Twice a day; cap, capsule; *d,* day; *h,* hour; *h.s.,* at bedtime; *MAOI,* monoamine oxidase inhibitor; *min,* minute; *NA,* not applicable; *PB,* protein-binding; *p.c.,* after meals; *PO,* by mouth; *q.i.d.,* four times a day; *supp,* suppository; *tab,* tablet; *t.i.d.,* three times a day.

- Note that milk of magnesia concentrate is three times as potent as regular-strength product.
- Give laxative 1 hour before or 1 hour after any oral antibiotic.

Senna
- Protect from light and heat.

Simethicone
- Administer after meals and at bedtime.
- If chewable tablets are ordered, instruct patient to chew tablets thoroughly before swallowing and follow with full glass of water.

Patient Teaching

General
- Advise patient that stool softeners are given to enable bowel movement without straining.
- Advise patient that measures to prevent and treat constipation include drinking 6 to 8 glasses of fluid per day, ingesting foods high in fiber (bran, fruits, vegetables), and increasing daily ambulation and activity. Instruct patients to avoid/minimize ingestion of gas-forming foods (beans, cabbage, onions) and to increase ambulation/activity.
- Advise patient regarding temperature and storage requirements for particular drugs.
- Caution patient that prolonged, frequent, or excessive use may result in dependence on drug or electrolyte imbalance.
- Advise patient that many laxatives contain sodium. Instruct patient to check with health care provider or pharmacist before using laxative if on low-sodium diet.

Docusate Sodium and Sennosides with Docusate Sodium
- Advise patient to drink at least six 8-oz glasses of liquid daily and to drink one glass of fluid with each dose. Patient should not take drug if already taking mineral oil or having acute abdominal pain, nausea, vomiting, or signs of intestinal obstruction. Patient should not use products for longer than 1 week and should report skin rash or if stomach or intestinal cramping occurs and does not diminish.
- Senna: Instruct patient that drug may discolor urine and feces to yellow-green; to discontinue drug if abdominal pain, nausea, or vomiting occurs; and that syrup form is 7% alcohol.
- Mineral oil: Instruct patient not to take other laxatives (e.g., docusate products) if she is already taking mineral oil; to take on an empty stomach; not to take with food or meals because of risk of aspiration and decreased fat-soluble vitamin absorption; to avoid bedtime doses because of risk of aspiration; and to report nausea, vomiting, diarrhea, or abdominal cramping.

Magnesium Hydroxide
- Advise patient that laxative action generally occurs in 4 to 8 hours and to take with full glass of water.

- Caution patient to note whether drug is regular or concentrated form (concentrate is three times more potent than regular strength).
- Advise patient that drug may interact with tetracyclines, digoxin (Lanoxin), indomethacin (Indocin), iron salts, and isoniazid and to notify health care provider if any of these drugs are used.
- Instruct patient to report any muscular weakness, diarrhea, or abdominal cramps.

Simethicone

- Advise patient that drug will help relieve flatus and associated pain and that it should be taken after meals; if chewable tablets are ordered, instruct patient to chew tablets thoroughly and drink full glass of water. If a dose is missed, patient should take it as soon as possible but should not take double doses.

Cultural Considerations

- In some cultures, pregnancy is considered a "cold" state, so warm foods and activities are encouraged to balance the body. Failure to do so, it is believed, may contribute to later poor health. For example, women of Mexican-American ethnicity may wish to avoid chilling and exposure to drafts and may not accept perineal cold compresses.
- Provide an interpreter with same ethnic background and gender if possible, especially with sensitive topics.
- Be culturally cognizant that different cultures discuss elimination in different ways. Be aware of cultural beliefs and practices.

Evaluation

- Evaluate for return of prepregnancy regular bowel function.

IMMUNIZATIONS

Rh$_0$(D) Immune Globulin

An Rh-negative patient who lacks the Rh factor in her own blood may carry a fetus who is either Rh-negative or Rh-positive. During pregnancy, minimal amounts of fetal blood may cross the placenta. Also, an abortion (spontaneous, therapeutic, or induced), amniocentesis, ectopic pregnancy, previa, and abruption result in some mixing of maternal and fetal blood. Subsequently, anti-D antibodies develop in an Rh-negative mother with an Rh-positive fetus; with the development of these antibodies, the mother becomes sensitized (Figure 55-1). If mother and fetus are both Rh-negative, no incompatibility exists to trigger the maternal antibody response, but if the fetus is Rh-positive, the Rh-negative mother is at risk for **Rh sensitization** (i.e., the development of protective antibodies against incompatible Rh-positive blood). The immune globulin IgM is formed and cannot cross the placenta. Later, IgD antibodies develop, which may cross the placenta with isoimmunization to the D antigen and subsequent hemolysis of fetal red blood cells. Prenatal D isoimmunization occurs in approximately 1% to 2% of Rh-negative women. In later exposure, as with subsequent pregnancies, there is a more rapid IgG (secondary) immune response and increased potential for fetal hemolysis in an Rh-positive fetus. The protective antibodies, once formed, remain throughout life and may result in hemolytic difficulties for fetuses in subsequent pregnancies. Maternal blood is assessed for the D antibody at the initial prenatal laboratory evaluation and at 26 to 28 gestational weeks. Human D immune globulin (RhoGAM, Rh$_O$[D] immune globulin) is routinely administered to women with maternal/fetal blood mixing, such as after abortion or with threatened abortion at any stage of gestation with continuation of the pregnancy, obstetrical trauma, obstetrical manipulation, or ectopic pregnancy. If abortion occurs up to and including 12 weeks' gestation, the microdose is administered if less than 2.5 mL of Rh incompatible red blood cells were administered. During the postpartum period, Rh$_O$(D) immune globulin should be administered within 72 hours. Therefore, one full dose (300 mcg) is given postpartum if the newborn is Rh positive, antepartum prophylaxis at 26 to 28 weeks' gestation, after amniocentesis, chorionic villus sampling, and percutaneous umbilical blood sampling. For women with abruption, previa, cesarean births, or manual placental removal, a Kleihauer-Betke analysis (serum test) should be done, because

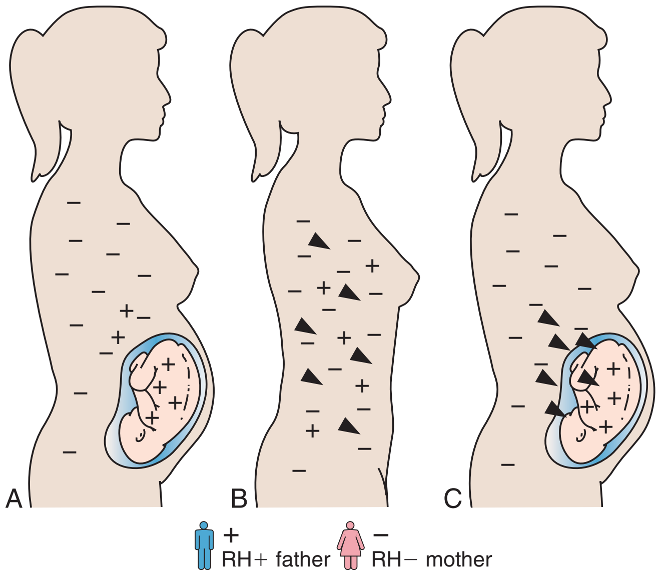

FIGURE 55–1 Understanding Rh isoimmunization. **A**, During pregnancy or delivery, a small amount of fetal blood may enter the mother's circulation. **B**, When the mother is Rh-negative and is pregnant with an Rh-positive fetus, the mother's immune system responds by producing anti-Rh$_O$(D) antibodies. **C**, In subsequent pregnancies, these antibodies cross the placenta and enter the fetal circulation; when the fetus is Rh-positive, the anti-Rh$_O$(D) antibodies will attack the fetal red blood cells and cause hemolysis.

TABLE 55-4 $RH_O(D)$ IMMUNE GLOBULIN

ROUTE AND DOSAGE	USES AND CONSIDERATIONS
IM in deltoid	Sterile concentrated solution of gamma globulin prepared from human serum containing antibodies to Rh factor (D antigen), also expressed as anti-$Rh_0(D)$. Administered to unsensitized Rh-negative patients. Suppresses active antibody response and formation of anti-$Rh_0(D)$ in Rh-negative patients exposed to fetal Rh-positive blood. Promotes destruction of Rh-positive fetal cells in maternal serum before mother can make antibodies that would cause hemolysis of fetal RBCs in Rh-positive fetuses and newborns in subsequent pregnancies. Use with caution in patients with thrombocytopenia, bleeding disorders, and IgA deficiency. Contraindicated in patients with known hypersensitivity to immune globulins or thimerosal, transfusion of $Rh_0(D)$-positive blood in previous 3 mo, or previous sensitization to $Rh_0(D)$. 1 vial (300 mcg) prevents maternal sensitization if fetal RBC volume that entered maternal circulation is <15 mL. If the estimated fetal blood and maternal mixing is >15mL, then an additional 300 mcg is administered. When >15 mL maternal-fetal blood mixing has occurred, a fetal RBC is performed to determine appropriate dose. Appears in breast milk (not absorbed by infant). Adverse reactions: lethargy, splenomegaly, elevated bilirubin, myalgia, temperature elevation; most commonly fever (still rare) and pain at injection site. Pregnancy category: C; t½: 23-26 d
300 mcg (1 vial) (standard dose)	Given at 26-28 wk gestation as prophylaxis and again after normal delivery (within 72 hours) with negative direct and indirect Coombs test. Also 300 mcg (standard dose) given after amniocentesis, chorionic villus sampling, percutaneous umbilical blood sampling, abdominal trauma, obstetrical manipulation, ectopic pregnancy, abortion, or threatened abortion at any stage of gestation with continuation of pregnancy. Larger than standard dose may be given if Kleihauer-Betke analysis shows that large fetal-maternal blood transfusion (>15 mL Rh positive RBCs) has occurred
50 mcg (1 vial) (microdose)	Given after abortion before 12 gestational wk if less than 2.5 mL of Rh incompatible RBCs were administered

d, Day; *IgA,* immunoglobulin A; *IM,* intramuscular; *mo,* month; *RBC,* red blood cell; *t½,* half-life; *wk,* week; *>,* greater than; *<,* less than.

TABLE 55-5 RUBELLA VIRUS VACCINE, LIVE, MSD

ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Given subQ: 0.5 mL into outer upper arm	Live virus vaccine for immunization against rubella (German measles). Dose is same for all persons, using either single-dose or multidose vials. Do not give immune serum globulin (ISG) concurrent with vaccine. Contraindicated in pregnant women and patients with anaphylactoid reactions to neomycin and/or gelatin, febrile respiratory illness or other febrile infection, active untreated tuberculosis, or immune deficiency conditions. Vaccinated persons can shed but not transmit virus. Defer vaccination for 3 months after blood or plasma transfusions and also after human serum immune globulin. Postpartum patients who received blood products may be vaccinated if repeat titer is drawn 6-8 wk later to ensure that seroconversion has occurred. Excreted in breast milk; use caution. Important for patient to use contraceptive method for 4 weeks following administration, because rubella is teratogenic. Rubella titer may be reassessed 3 mo after administration. Side effects: burning, stinging at injection site; malaise; fever; headache; slight rash 2-4 wk after injection; joint pain 1-3 d within 1-10 wk of injection. Pregnancy category: C

d, Day; *mo,* month; *subQ,* subcutaneous; *wk,* week.

more than 15 mL of fetal-maternal hemorrhage of Rh-positive red blood cells may have occurred, necessitating an increased dose of $Rh_O(D)$ immune globulin. When 15 mL or more of Rh positive red blood cells is suspected, a fetal red blood cell count should be performed to determine the appropriate dose.

The Rh sensitization process can be prevented through the administration of **$Rh_O(D)$ immune globulin** (RhoGAM) to unsensitized Rh-negative patients after each actual or potential exposure to Rh-positive blood (Table 55-4).

Adverse Reactions

Adverse reactions include hypotension, chills, dizziness, fever, headache, pruritus, rash, abdominal pain, diarrhea, and injection site reactions (discomfort, mild pain, redness, swelling).

Rubella Vaccine

Maternal rubella, also called German measles, is a potentially devastating infection for the fetus, depending on gestational age. If an unimmunized woman (rubella titer <1 : 10 or negative titer) contracts the virus during the first trimester, a high rate of abortion and neurologic and developmental sequela associated with **congenital rubella syndrome** (transmission of the rubella virus to the fetus via the placenta) may result. Cataracts, glaucoma, deafness, heart defects, and mental retardation are seen with this syndrome. When infection occurs after the first trimester, there is less risk of fetal damage because of the developmental stage of the fetus. There is no treatment for maternal or congenital rubella infection. The goals are immunization and prevention of rubella in patients of childbearing age (Table 55-5).

Adverse Reactions

Side effects are generally mild and temporary. Burning or stinging at the injection site is caused by the acidic pH of the vaccine. Regional lymphadenopathy, **urticaria** (skin rash caused by an allergic reaction), rash, malaise, sore throat, fever, headache, polyneuritis, arthralgia, and moderate fever are occasionally seen.

Nursing Process

Patient-Centered Collaborative Care

RhO(D) Immune Globulin

Assessment

- Determine blood type and Rh status of all prenatal patients.
- Assess patient for understanding of both her own and her partner's Rh status.
- Ask patient about previous pregnancies and their outcome; ask whether she has ever received Rh_O(D) immune globulin.
- Follow agency policy for Rh blood testing for patient and infant at time of delivery.
- Postpartum, assess data about neonate's Rh type. If infant is Rh negative, drug is not needed. If infant is Rh positive and Rh-negative mother is not sensitized (negative indirect Coombs test) and infant has a negative direct Coombs test, mother is a candidate to receive the injection to prevent antibody production or "sensitization."
- Obtain patient's written consent before administration. Some agencies require a refusal form if the drug is declined.
- Assess for history of allergy to immune globulin products.

Nursing Diagnoses

- Deficient knowledge related to maternal/fetal Rh incompatibility and sensitization
- Deficient knowledge related to Rh_O(D) immune globulin purpose, action, and side effects

Planning

- Patient will receive Rh_O(D) immune globulin as indicated within 72 hours after delivery or abortion.
- Patient will be able to discuss Rh sensitization and actions indicated during subsequent pregnancies.

Nursing Interventions

- Document Rh workup and eligibility of patient to receive drug. Convey information in verbal report and in patient record using agency policy.
- Check lot numbers on vial and laboratory slip for agreement before administration; check expiration date. Check identification band and laboratory slip for matching number. Return required slips to laboratory or blood bank.
- Administer Rh_O(D) immune globulin: dose (microdose/standard dose) according to gestational weeks and exposure and route, according to provider orders and agency. Administer intramuscularly (IM). Normally administered in deltoid muscle within 72 hours after delivery, but if more than 72 hours has passed, administer as soon as possible up to 28 days; a lesser degree of protection may result.
- Intravenous (IV) administration of Rh_O(D) immune globulin is possible, though infrequent. Check provider orders and dose. For IV administration, reconstitute with normal saline. Store at 36° F to 46° F (2° C to 8° C).
- Have epinephrine available to treat anaphylaxis.

Patient Teaching

General

- Explain action, purpose, and side effects of drug.
- Advise patient to avoid live virus vaccines for 3 months after administration.
- Provide written documentation of date of administration for patient's personal health record.

Cultural Considerations

- Provide an interpreter with same ethnic background and gender if possible, especially with sensitive topics.
- Assess patient's religious beliefs. Some patients may refuse Rh_O(D) immune globulin, considering it to be a blood product.

Evaluation

- Evaluate patient's understanding of need for Rh_O(D) immune globulin.

DRUGS ADMINISTERED TO THE NEWBORN IMMEDIATELY AFTER DELIVERY

Drugs administered to the newborn in the immediate period after birth are (1) erythromycin ophthalmic ointment to provide prophylaxis against eye infections (required by U.S. public health law and all states) and (2) vitamin K (Phytonadione, Mephyton) to prevent hemorrhagic disease of the newborn (Table 55-6). Antiinfective agents may be applied to the cord stump (e.g., alcohol, brilliant green/proflavine hemisulfate/gentian violet) during the first few hours after birth; however, literature supports "dry cord care" with no agents applied.

Side Effects and Adverse Reactions

Erythromycin Ophthalmic Ointment. Side effects include chemical conjunctivitis in about 20% of neonates, manifesting as edema and inflammation lasting about 24 to 48 hours.

TABLE 55-6 DRUGS ADMINISTERED TO THE NEWBORN IMMEDIATELY AFTER DELIVERY

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
erythromycin ophthalmic ointment (Ilotycin Ophthalmic)	½-inch ribbon of ointment placed in lower conjunctival sac of each eye (beginning at inner canthus) within 1 h of delivery	Prevention of gonococcal conjunctivitis and chlamydial conjunctivitis **(ophthalmia neonatorum)**, which can cause blindness. Source of infection is birth canal. Contains antibiotic (erythromycin) in sterile base of mineral oil and white petrolatum. Has bactericidal or bacteriostatic action based on concentration per gram and target organisms present. Mandatory administration in U.S. Side effects: Chemical conjunctivitis (swelling, inflammation 24-48 h)
phytonadione, Vitamin K_1 (Mephyton, Aqua-MEPHYTON)	0.5-1 mg IM in vastus lateralis (preferably) or rectus femoris within 1 h after birth (check health care provider or agency standing orders for dosage)	Prevention of hemorrhagic disease of the newborn. Anticoagulant antagonist. Aqueous colloidal solution of vitamin K_1. Newborn does not receive adequate vitamin K transplacentally and unable to synthesize vitamin initially because of limited intestinal flora; therefore production of clotting factors in liver is hindered and low prothrombin levels are evidenced. Phytonadione facilitates production of clotting factors equal to natural vitamin K. Newborns of mothers who received oral anticoagulants, anticonvulsants, antituberculosis drugs, or recent antibiotics during pregnancy may need a higher dosage 6-8 h after first injection. Side effects: Pain and edema at injection site; possible allergic reactions include urticaria and rash; those who receive larger doses may exhibit hyperbilirubinemia and jaundice.

h, Hour; *IM,* intramuscular.

It may interfere slightly with eye-to-eye contact between parents and the neonate.

Vitamin K. Side effects include pain and edema at the injection site. Some allergic reactions, manifested by urticaria and rash, have been reported. Neonates who receive larger doses may exhibit hyperbilirubinemia and jaundice resulting from competition for binding sites.

Immunization during the Newborn Period before Discharge

The American Academy of Pediatrics and the Centers for Disease Control and Prevention (CDC) have recommended that immunization against hepatitis B virus (HBV) begin in the newborn period. HBV infection may result in serious long-term liver disease, cancer, and death in adulthood. The goal of immunization is to reduce the number of chronic carriers of the virus in the population, thus preventing HBV infection.

In pregnancy, HBV transmission occurs vertically, primarily at the time of delivery. Recombinant hepatitis B (Engerix-B, Recombivax HB) provides passive immunization for the newborn (Table 55-7). The current recommendation is that newborns receive recombinant hepatitis B (Engerix-B Pediatric, Recombivax HB) and, if appropriate, hepatitis B immune globulin (HBIG) injections IM in the anterolateral thigh (vastus lateralis [preferred] or rectus femoris muscles) following a protocol based on the mother's HBsAg-positive or -negative status. These injections require signed maternal consent before administration. Infants born to HBsAg-negative mothers will receive only recombinant hepatitis B. Infants born to HBsAg-positive mothers will receive concurrent injections of both hepatitis B immune globulin and hepatitis B vaccine in separate sites within 12 hours of birth, because it is believed that infection can be prevented in 90% of newborns. Determine the mother's HBsAg status as soon as possible. If the mother's HBsAg status is unknown, administer the HepB immunization within 12 hours of delivery. Hepatitis B immune globulin can be given to infants no later than 1 week of age if the mother is HBsAG-positive, but should be given within 12 hours of birth.

Nursing Process
Patient-Centered Collaborative Care

Measles-Mumps-Rubella Vaccine

Assessment

- Review history and laboratory results to determine need for measles-mumps-rubella (MMR) vaccine.
- A rubella titer of less than 1:8/1:10 (agency laboratory), negative, or not immunized indicates the need for MMR vaccine administration.
- MMR vaccine is contraindicated if patient verbalizes (or if medical record review indicates) any of the following. Document the presence of any of these factors:
  - Pregnancy
  - Receipt of whole blood transfusions, plasma transfusion, or human immune serum globulin within the past 3 months
  - History of anaphylactic or anaphylactoid reactions to neomycin (dose contains 25 mcg of neomycin), gelatin, or gelatin-containing products

TABLE 55-7 HEPATITIS B IMMUNIZATION IN THE NEWBORN PERIOD

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
hepatitis B vaccine (Engerix-B, Recombivax HB)	For newborns of mothers who have HBsAg-negative, HBsAg-positive, or unknown HBsAg status: Engerix-B: 0.5 mL (10 mcg) IM within 12 h after birth (first dose); second dose at 1-2 mo, and final dose at >24 weeks (6 mo). Recombivax HB: 0.5 mL (5 mcg) IM within 12 h after birth (first dose), repeated at 1 mo and 6 mo.	A recombinant vaccine that provides passive immunization against all subtypes of HBV. Given to all infants regardless of HBsAg status of mother. Unvaccinated infants <12 mo with mother or primary caregiver with acute hepatitis B are given HBIG because of risk for becoming HBV carrier following infection (also start HBV vaccine series). Iinject IM into vastus lateralis (preferably) or rectus femoris; never inject IV. Following three doses, >90% of infants and children will seroconvert 95%-99%. Protection in those who seroconvert will last 3-7 y with single booster. Contraindicated in patients with hypersensitivity to any component of vaccine or yeast. Neonatal side effects: soreness at injection site with edema, warmth, erythema, and induration. Pregnancy category: C Newborns of HBsAg-positive mothers should also receive HBIG 0.5 mL IM within 12 h of birth. May be given concurrently with first dose of hepatitis B vaccine in separate site (opposite thigh). Newborns of mothers with HBsAg-unknown status whose maternal results are positive within 7 days of birth should receive HBIG (0.5 mL) IM in thigh not used for vaccine.

h, Hour; *HBIG,* hepatitis B immune globulin; *HBsAg,* hepatitis B surface antigen; *HBV,* hepatitis B virus; *IM,* intramuscular; *IV,* intravenous; *mo,* month; *y,* year; *>,* greater than.

Receipt of other virus vaccines within 1 month (Do not give less than 1 month before or after other virus vaccines.)
Immunosuppressed, radiation therapy, untreated active tuberculosis (TB), AIDS, or symptomatic HIV
Blood dyscrasias, leukemia, lymphomas of any type, or other malignant neoplasms affecting bone marrow or lymphatic system
Any febrile or respiratory illness or other acute illness

- Determine whether patient is also a candidate to receive $Rh_O(D)$ immune globulin. Administration of both drugs may result in suppression of rubella antibodies with need to recheck rubella titer in approximately 3 months.

Nursing Diagnoses

- Deficient knowledge related to risk for rubella infection and benefit of prevention in patients of childbearing age
- Risk for fetal injury related to rubella infection in subsequent pregnancy secondary to lack of immunity

Planning

- Patient will receive MMR vaccine to protect against rubella.
- Patient will plan to prevent pregnancy for 4 weeks after subQ injection.

Nursing Interventions

- Protect vaccine from light, and store at 35.6° F to 46.4° F (2° C to 8° C) before reconstitution.
- Reconstitute with diluent provided, and administer within 8 hours. Administer 0.5-mL vaccine subQ in upper outer arm. Do not administer IV.
- If tuberculin skin test is to be done, administer it before or simultaneously with rubella vaccine (may have temporary depression in tuberculin skin sensitivity). If MMR has been given before tuberculin skin test, postpone tuberculin skin test until 4 to 6 weeks after MMR administration. If giving both simultaneously, use the Mantoux test.

Skill: Reconstitution

- Single-dose vial: withdraw entire amount of diluent into syringe.
- Inject total volume into vial of lyophilized vaccine, and agitate to mix thoroughly.
- Withdraw entire contents into syringe, and inject total volume of restored vaccine.
- Have epinephrine readily available in case of anaphylactic reaction.
- Clearly convey in verbal report and documentation that vaccination has occurred.
- Record date of administration, lot number, manufacturer, name, and title to comply with agency policy.

Patient Teaching

General

- Discuss with patient the importance of immunity to rubella, and help her understand the need to obtain titers to determine immune status.

- Discuss the importance for use of effective contraception for 4 weeks after vaccine injection. Identify contraceptive method of choice, and document instruction.
- Reassure patient that there is no risk to her from being near small children who received the injection, even if she is pregnant and not immune.
- Advise patient regarding drug action, purpose, and side effects.
- Recommend that patient have titer rechecked in 3 months if she also received Rh_O(D) immune globulin.

Side Effects

- The most common side effect is burning or stinging at injection site; some also experience malaise, fever, headache, and slight rash about 2 to 4 weeks after injection. About 1 to 10 weeks after injection, some may experience joint pain that lasts 1 to 3 days.

Cultural Considerations

- Some cultures are opposed to vaccinations. Clarify with the family their desires regarding vaccinations. Explore the legal requirements for vaccinations in your state.

Evaluation

- Evaluate the need for MMR vaccine and administration to patients with titer less than 1 : 8/1 : 10 (agency laboratory), not immunized, or negative titer.

Nursing Process
Patient-Centered Collaborative Care

Drugs Administered to the Newborn after Delivery

Assessment

Erythromycin Ophthalmic Ointment
(Ilotycin Ophthalmic)

- Assess newborn for signs of hypersensitivity.

Phytonadione, Vitamin K

- Assess newborn for bleeding from umbilical cord, circumcision site, nose, and gastrointestinal tract, and for generalized ecchymoses.

Nursing Diagnoses

- Risk for neonatal injury related to infectious process (congenital) or transient low prothrombin levels in newborn

Planning

- Neonate will experience minimal or no side effects from drugs routinely administered after delivery.

Nursing Interventions

Erythromycin Ophthalmic Ointment

- Refer to Chapter 13 for procedure for administration of eye ointment.
- Promote bonding by facilitating eye contact between parents and infant during this period, but delay instillation no longer than 1 hour after delivery.
- Wear gloves for administration of eye ointment. Do not place tube of ointment under radiant warmer with infant before administration.
- Administer erythromycin ophthalmic ointment before administration of phytonadione and hepatitis B (with maternal consent only) injections. Infant may cry after injections, making administration of ophthalmic ointment more difficult.
- Administer erythromycin ophthalmic ointment (ribbon of ointment about 1 cm long) from inner canthus to outer canthus in lower conjunctival sac of each eye. Do not touch eye with applicator.
- Following administration, close eyes to more evenly distribute ointment. After 1 minute, may blot eye with gauze to remove excess ointment. Do not irrigate eyes after instillation.

Phytonadione, Vitamin K

- Protect drug from light because of photosensitivity of the preparation.
- Cleanse anterolateral site before injecting drug; if alcohol is used, allow to dry before drug administration.
- Wear gloves when administering.
- If phytonadione is in a glass vial, withdraw medication with filter needle. Change needles and use a 25-gauge, ⅝-inch needle to administer into the vastus lateralis muscle.
- Stabilize infant's leg before administration.
- Observe injection site for edema and inflammation (Figure 55-2). Refer to Chapter 13 for a complete discussion of safe pediatric drug injection sites.
- Administer before circumcision.

Patient Teaching

Erythromycin Ophthalmic Ointment

- Instruct parents regarding drug action, purpose, and side effects. Advise parents that drug administration is mandatory in the United States.
- Tell parents that any edema around eyes usually disappears within 24 to 48 hours.
- Explain that administration of eye prophylaxis is federally and state mandated and that there is no risk to vision from the ointment.

Phytonadione

- Instruct parents regarding drug action, purpose, and side effects.

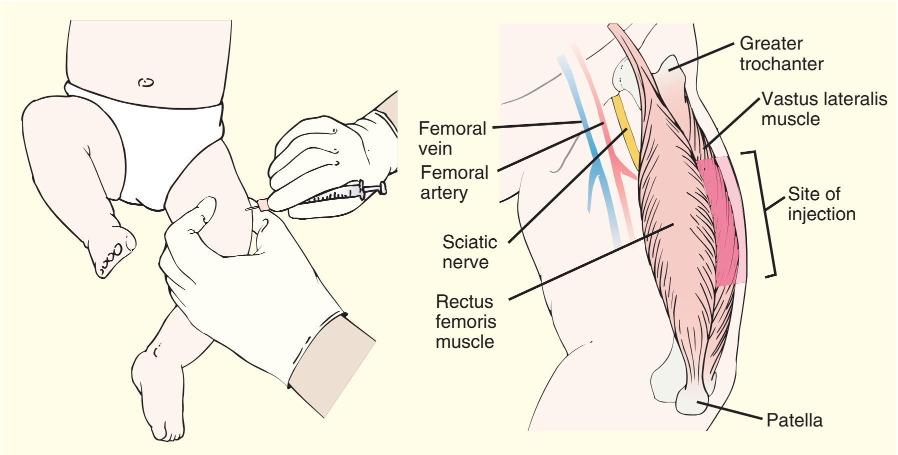

FIGURE 55–2 Site for giving an intramuscular injection to a newborn shortly after birth.

Evaluation

- Evaluate for newborn bleeding, specifically on days 2 and 3 after administration of phytonadione.
- Evaluate for drug hypersensitivity or side effects.
- Evaluate parents' understanding about medications administered to their newborn.

Nursing Process
Patient-Centered Collaborative Care

Hepatitis B Vaccine

Assessment

- Review prenatal record laboratory data for maternal HBsAg status. Validate whether infant is to receive hepatitis B vaccine singly or in concert with HBIG.
- Assess parental knowledge of immunizations, purpose, and childhood immunization schedule.
- Assess for hypersensitivity to yeast (recombinant HB).
- Assess for written maternal consent for newborn vaccine before administration.

Nursing Diagnoses

- Deficient knowledge related to hepatitis B, maternal prophylaxis, and pediatric immunization schedule
- Risk for neonatal injury related to maternal hepatitis B infection

Planning

- Newborn will receive correct dosage of hepatitis B vaccine before discharge. HBIG 0.5 mL is best given within 12 hours of birth if mother is HBsAG-positive.
- Newborn's caregiver will keep scheduled appointments with primary health care provider and verbalizes plans to continue childhood immunizations as recommended by current immunization schedule.

Nursing Interventions

- Shake vial well before withdrawal of medication.
- Discard if other than slightly opaque white suspension.
- Cleanse anterolateral site before injecting drug. If alcohol is used, allow to dry before drug administration.
- Inject complete contents of vial; do not dilute.
- Have epinephrine available for allergic reaction.
- If mother refuses hepatitis B vaccine or HBIG, note in maternal and newborn chart. Assess agency policy; most agencies document medication refusal and also notify local community health department. Monitor newborn's postinjection temperature per agency policy.
- Give IM in vastus lateralis.
- Document administration and site in chart.
- Record lot number, expiration date, name, and title in chart.
- Store product at 35.6° F to 46.4° F (2° C to 8° C).
- Do not freeze (freezing destroys potency).
- Do not confuse hepatitis B vaccine with HBIG or Haemophilus B (Hib, ActHIB) vaccine, because these drugs have different dosages.

Patient Teaching

- Inform patient of implications of her HBsAg-positive or HBsAg-negative status for her newborn, and recommend interventions.
- Have patient read literature and sign consent form for vaccine administration. Place original/copy in newborn's chart per agency policy. Instruct parents regarding childhood immunizations as recommended by current immunization schedule, and inform them when repeat doses should be given. Give parents written information regarding immunization schedule and infant immunization record. Document administration of hepatitis B vaccine on infant immunization record.

Cultural Considerations

- Japanese women may prefer to take their postpartal medications with warm water rather than with cold water.
- Cultural values influence infant care. It is important for nurses to be culturally sensitive to the pregnant patient's cultural belief framework and to try to include this framework, as appropriate, in provision of care and establishing rapport with the patient.

Evaluation

- Evaluate parents' understanding of need for hepatitis B vaccine for newborn.

CRITICAL THINKING CASE STUDY

TA, an older adolescent, was admitted to the hospital for labor induction/augmentation with signs and symptoms of gestational hypertension at 42 weeks' pregnant (gravida 4, para 1). TA's mother arrived at the hospital when TA was 8 cm dilated, in time for the late stages of TA's labor. Her mother remained as TA's support person throughout the delivery, which occurred at 6:00 AM by vacuum extraction. TA had a continuous epidural for her labor and delivery. An episiotomy was performed at the time of delivery, and a fourth-degree laceration occurred. A cluster of hemorrhoids was evident. Baby JA, weighing 8 lb 7 oz, had Apgar scores of 7 and 9. The infant is alert and active.

TA lives with her parents and has been going to high school while working part time in an automotive parts store. TA wants to keep her infant and to breastfeed "for at least 3 months." She plans to finish school and return to work in 6 weeks.

Immediately after the delivery, the nurse conducts an assessment of TA, analyzes the data, and determines and prioritizes TA's nursing care needs. The same is done for the newborn.

1. Based on the data supplied about her delivery, what is the priority nursing diagnosis for TA?
2. What is a goal for the diagnosis given?
3. How should the nurse intervene in regard to the episiotomy during the early postpartum period, integrating both pharmacologic and nonpharmacologic measures? Orders include benzocaine spray, witch hazel pads, pramoxine hydrochloride, and ibuprofen (Advil, Motrin) tablets (200 mg) at the bedside.
4. TA says that her grandmother wants her to eat warm soup that she will bring to the hospital. The grandmother has also told TA not to take a shower for 4 weeks. What further assessment is necessary?

   Baby JA's newborn medications must be administered within the first hour after delivery. Bonding for TA and JA should also be promoted at this time.
5. Within the standard, how should bonding be promoted, including eye contact between mother and infant, while eye prophylaxis is also administered?
6. What steps should the nurse follow to instill ointment into the infant's eyes, including safety for the nurse administering the ointment?
7. What should TA be taught about the side effects of eye prophylaxis?
8. How should the nurse explain the reason for the vitamin K_1 injection for the infant in terms TA can understand?
9. What steps should the nurse follow to prepare and give the vitamin K_1 injection, including safety for the nurse administering the injection?

   TA is Rh negative. The blood type of the infant's father is unknown. Cord blood was drawn on the infant at the time of delivery. Based on TA's historical data, what is a concern in terms of defining TA as a likely or unlikely $Rh_O(D)$ immune globulin candidate? What information about the mother and the infant is needed to aid in the decision?
10. Assuming TA is a $Rh_O(D)$ immune globulin candidate, what is a nursing diagnosis for TA?
11. What is an outcome-based goal for the diagnosis given?
12. What is the timeframe in which $Rh_O(D)$ immune globulin should be administered? Explain your answer.
13. What is appropriate verbal and written documentation in regard to $Rh_O(D)$ immune globulin administration, both before and after administration?
14. TA's chart reveals that her rubella titer is 1 : 6. What orders should be expected in regard to rubella vaccine?
15. Neomycin is listed as a known allergy in TA's medication administration record. Considering TA's titer, the standing health care provider's order, and knowledge about this vaccine, how should this situation be handled?
16. In a situation in which a newborn's mother is both a rubella and a $Rh_O(D)$ immune globulin candidate, with

both products being administered, what is the focus of patient teaching for TA in regard to the rubella titer?

Because of her episiotomy, TA is concerned about her first postdelivery bowel movement. It is explained to her that the docusate with sennosides product in her self-administered medication packet will help.

17. TA says that she does not want to take the docusate because she plans to breastfeed. What is the appropriate nursing diagnosis based on TA's communication?
18. How should the nurse address TA's concerns, based on knowledge of the product and breastfeeding?

TA asks what can be done about her hemorrhoids. The mode of action of the ordered pharmacologic products is explained to her. She then states, "So I just have to insert this syringe-type applicator into my rectum once I fill it from the big can?"

19. Analyze TA's statement. What is correct and incorrect concerning the knowledge?
20. What nursing diagnosis is appropriate for TA based on the information supplied?
21. What patient teaching is needed for TA?

Baby JA is ordered to receive hepatitis B vaccine before discharge. TA is HBsAg-negative.

22. Which newborns are eligible to receive hepatitis B vaccine?
23. How many doses constitute the total series, and what is the duration for these?
24. Why is this vaccine given to newborns? Why is it important?
25. TA asks how long the infant's immunity should last. What is the nurse's best response?
26. Where would one expect to find the vaccine stored?
27. What is the written documentation required with administration of this vaccine?

NCLEX STUDY QUESTIONS

1. A patient asks the nurse why her baby is receiving a vitamin K injection. The nurse's best response is based on what knowledge?
   a. Vitamin K causes an increase in newborn platelets.
   b. A newborn's liver is too immature to produce vitamin K.
   c. A newborn cannot synthesize vitamin K without intestinal flora.
   d. Vitamin K is not produced in bone marrow until an infant is 8 days old.
2. In assessing a postpartum patient, the nurse notes saturation of two peri-pads in less than 1½ hours. What is the priority intervention?
   a. Palpate the fundus, and massage if boggy.
   b. Prepare to administer pitocin IV.
   c. Prepare to administer methylergonovine.
   d. Assess maternal blood pressure and pulse for hypovolemic shock.
3. Two hours after delivery, a patient is complaining of pain from her episiotomy. What is the most effective nursing intervention?
   a. Sitz bath for 20 minutes
   b. Application of cold compresses to the perineum
   c. Application of a hydrocortisone acetate suppository
   d. Teaching patient how to use Hydrogel pads to the area
4. A postpartum patient is being discharged from the hospital. The nurse notes that she is Rubella-negative and administers the MMR vaccine. The nurse's teaching includes which instruction?
   a. Avoid people who are immunocompromised for 1 week
   b. Continue to take prenatal vitamins for at least 3 months postpartum
   c. Use a reliable contraceptive for 1 month postpartum
   d. Take ibuprofen 800 mg three times a day for up to 2 weeks
5. It is mandatory to have maternal signed consent before administering which newborn medication?
   a. Erythromycin ophthalmic ointment
   b. Phytonadione
   c. Hepatitis B vaccine
   d. Betamethasone
6. Before administering MMR vaccine to a postpartum patient at discharge, the nurse is reviewing the patient's history for allergies. The nurse plans to withhold the vaccine and notify the health care provider after noting a patient allergy to which item?
   a. Baker's yeast
   b. Eggs
   c. Duck meat or duck feathers
   d. Neomycin
7. The nurse is mentoring a new graduate who is preparing to administer the phytonadione injection to a newborn. Which muscle sites selected by the new graduate would indicate the need for further teaching? (Select all that apply.)
   a. Anterolateral thigh
   b. Vastus lateralis
   c. Rectus femoris
   d. Gluteus maximus
   e. Vastus medialis
8. The nurse is preparing to administer an ophthalmic medication to a newborn. Education for the parents includes which fact about the medication?
   a. Infants of mothers who test positive for syphilis receive this medication.
   b. Eye ointments are administered in the bottom of the eye from the inner to the outer eye.
   c. This medication will prevent congenital cataracts.
   d. Infants with a negative direct Coombs test receive this medication.

9. In assessing a postpartum patient, the nurse notes saturation of one peri-pad in less than 15 minutes and a boggy uterus. The patient is 15 minutes postpartum with vital signs of T 99.7, P 92, R 18, and BP 142/86. The nurse performs fundal massage. Based on the patient's assessment data, the most appropriate nursing action is to withhold which medication?
   - a. Carboprost (Hemabate) 0.25 ampule IM
   - b. Methylergonovine (Methergine) 0.2 mg IM
   - c. Oxytocin (Pitocin) 20 units in 1000 mL of lactated Ringer's solution IV
   - d. Bolus of lactated Ringer's solution
10. A newborn is admitted to the nursery. The nurse reviews the maternal history. It is important that the nurse assess the mother's status specific to which infectious process(es)? (Select all that apply.)
    - a. Rubeola
    - b. Hepatitis A
    - c. Hepatitis B
    - d. HIV/AIDS
    - e. Group B streptococcus
11. A newborn, whose mother is HBsAg positive, is admitted to the nursery. Which immunizations are appropriate for this newborn? (Select all that apply.)
    - a. Hepatitis B immune globulin
    - b. HepB
    - c. *Haemophilus influenzae* type b
    - d. Hepatitis A
    - e. Phytonadione

Answers: 1, c; 2, a; 3, b; 4, c; 5, c; 6, d; 7, a, c, d, e; 8, b; 9, b; 10, c, d, e; 11, a, b, e.

CHAPTER

OBJECTIVES

- Recognize that successful contraception is essential to the health and well-being of women.
- Describe methods of contraception commonly prescribed, patient selection, mechanisms of action, and possible side effects.
- Identify specific nursing actions that will enhance successful contraception for women and their partners.
- Describe the nursing process, including teaching and risk-benefit–alternative education associated with medications used for contraception and family planning.
- Provide information for nonpharmacologic and pharmacologic interventions for women experiencing menopausal symptoms.
- Differentiate between types of medications used for osteoporosis.
- Describe the nursing process, including teaching and risk-benefit–alternative education associated with medications used for menopausal symptoms

mittelschmerz, p. 847
oligomenorrhea, p. 856
osteopenia, p. 868
osteoporosis, p. 851
pelvic inflammatory disease, p. 859
progestin, p. 846
withdrawal bleeding, p. 848

Women have specific health care needs throughout their reproductive and postreproductive life cycle. Women's reproductive life cycle begins with **menarche,** the start of spontaneous menstruation, and continues through **menopause,** the permanent cessation of menstruation. Successful contraception is essential to the health and well-being of sexually active women of reproductive age. Successful adaptation to menopause, control of menopausal symptoms, and continued sexual wellness is essential to the health and well-being of older women. This chapter reviews pharmacologic products that may be used throughout the reproductive and menopausal life cycle of women.

In 2011, the Department of Health and Human Services classified contraception as a preventative service under the Affordable Care Act. For many women, this law will reduce the cost of contraception methods and improve access to health care providers.

ESTROGEN-PROGESTIN COMBINATION PRODUCTS

All estrogen-progestin combination products (also known as **combined hormone contraception** [CHC] products) contain a synthetic version of *estrogen* and a compound known as *progestin*. **Ethinyl estradiol** (EE) is the most commonly used synthetic estrogen found in CHC products. An older form of estrogen, **mestranol**, is found in higher-dose (≥50 mcg) oral combination products. Mestranol is converted into ethinyl estradiol in the body. Contraception products with high levels of ethinyl estradiol or mestranol are prescribed only in certain circumstances. Newer CHC products, including low-dose contraception pills, contain only EE as the estrogen component. **Progestins** are natural or synthetic hormones that have *progesterone-like* effects. **Progesterone** is the naturally occurring sex hormone produced in the ovaries of women. **Progestogen** refers to any synthetically produced progesterone compound. Almost all progestins are derivatives of testosterone, a steroid hormone classified under the androgen group. The term *progestin* will be used to describe the compound used in CHC products. Not only do progestins have contraceptive properties, they serve to balance out the effects of estrogen.

One of eight different types of progestins is used in CHC products. Norethindrone, norethindrone acetate, and ethynodiol diacetate are first-generation progestin compounds that were the earliest progestin formulations to be used in contraception pills. Second-generation progestins include noresthisterone and levonorgestrel (LNG). LNG is the most commonly used progestin worldwide. Third-generation progestins, also referred to as *new generation* progestins, include desogestrel (etonogestrel), gestodene, and norgestimate. The new generation progestins have a higher efficacy rating and fewer effects on lipid and carbohydrate metabolism when compared to their earlier counterparts. They also have fewer androgenic side effects, which are described later in this chapter.

Drospirenone (DSRP) is a new-generation progestin derived from spironolactone. Because spironolactone is a potassium-sparing diuretic hormone, it can increase serum potassium levels in women taking CHC pills with DSRP, altering water and electrolyte balance. A progestin that comes in an injectable form is medroxyprogesterone acetate (MPA).

Amount of estrogen and type of progestin determine bioactivity and possible side effects of CHC products. The combination of estrogen and progestin causes the products to have estrogen-like activity or *estrogenic activity,* progesterone-like activity or *progestational activity,* and androgen-like activity or *androgenic activity*. The combination of estrogen and the selected progestin also has an effect on the uterine endometrium. The lowest effective dose that successfully prevents conception should be used.

Mechanism of Action

The estrogen component of combined hormone contraceptive products inhibits ovulation by preventing the formation of a dominant follicle. When a dominant follicle does not mature, estrogen remains at a consistent level and is unable to reach the peak level needed to stimulate the luteinizing hormone (LH) surge. The progestin component also suppresses the LH surge. When the LH surge is suppressed, ovulation is prevented and pregnancy does not occur. Any cycle, whether induced by drugs or naturally occurring, in which ovulation does not occur is called an *anovulatory* cycle.

Therefore, CHCs produce drug-induced anovulatory cycles. The estrogen component of CHC products also stabilizes the uterine endometrium, inhibiting proliferation and secretory changes and decreasing occurrence of irregular and/or heavy bleeding. The progestational effects of progestin change the endometrium to make it less favorable for implantation of a fertilized ovum. In addition, progestins have an effect on the quantity and viscosity of the cervical mucus, making it thick and hostile to sperm penetration. Progestins alter the motility of both the muscles of the fallopian tube and the cilia within the tube, impeding the movement of the ovum through the tube.

Route of Delivery

There are several routes of administration for combined hormone contraception products. Most women are familiar with oral contraception, in which a pill is ingested daily, absorbed by the gastrointestinal tract, and metabolized by the liver. CHC products can also be administered through a transvaginal and transdermal route, under the trade names of NuvaRing and the Ortho-Evra transdermal contraceptive patch, respectively. The advantage of these alternative sites for administration is avoiding gastrointestinal absorption and the initial metabolism by the liver, or the "first-pass" effect. Theoretically, side effects such as nausea and vomiting, heart and circulatory risks, and noncompliance with a daily dosage regime may be avoided. Intramuscular and subcutaneous routes of administration for combined hormone contraception are not available in the United States.

Combined Oral Contraception Products

Combined oral contraception (COC) products are one of the most commonly used methods of reversible contraception in the world because of their ease of use, high degree of effectiveness, and relative safety. The theoretical effective rate (absolute correct use) for COC is 99.3%, while typical use effective rate (accounting for patient error) is around 92%. This means that the COC is 92% to 99.3% effective for contraception. When the pill was approved for use by the U.S. Food and Drug Administration (FDA) in 1960, little was known about the best combination of estrogen and progestin or their optimum effective doses. In the 1970s, research provided evidence that the adverse side effects, particularly heart and circulatory effects, were directly related to the dose of estrogen in the oral contraception product. The higher dose of estrogen increased risk for venous thromboembolism (VTE), myocardial infarction (MI), and stroke. Subsequently, "low-dose" oral contraception pills and, more recently, "very low-dose" contraception pills have been introduced. Low-dose COC pills greatly reduce the risk for dangerous side effects. A low-dose COC product contains ≤35 mcg of ethinyl estradiol or ≤50 mcg or less of mestranol and a progestin. Very low-dose CHC pills contain ≤20 mcg of EE and a progestin. Research continues to focus on actual and potential short- and long-term benefits and risks associated with use of low-dose oral contraceptives, particularly in the areas of heart and circulatory risks as well as carcinogenesis. Clinical studies also continue to investigate the venous circulatory effects of new-generation progestins.

COC formulations are differentiated based on the strength of the estrogen component, type of progestin used, and whether estrogen or progesterone (and androgen) activity predominate. Increased estrogenic activity may include side effects such as cyclic breast changes, **dysmenorrhea** (painful periods), **menorrhagia** (heavy periods), **chloasma** (hyperpigmentation of the skin), and VTE, while decreased estrogenic activity may cause **amenorrhea** (absence of periods) or spotting at certain points in the cycle. Increased progestational activity may cause weight gain, depression, fatigue, and decreased libido, while lack of progestational activity may cause **breakthrough bleeding** (BTB) and headaches. BTB is an episode of bleeding that occurs during the active pill cycle of COC products. It is more common at the start of COC use, when a woman changes her COC type of pill, and with progestin-only preparations of contraception. There is no evidence that an episode of BTB is associated with a decrease in the COC's effectiveness as long as the patient continues to take the pill on daily basis and as prescribed. Increased androgenic activity may cause acne, hirsutism, edema, and cholestatic jaundice. The estrogens and progestins in oral contraception pills also have an effect on the uterine endometrium, which may cause changes in the patient's periods, such as irregular bleeding, heavy or light periods, or spotting between periods. The undesirable side effects of hormonal contraception products are discussed later in this chapter.

Most women on COC products experience shorter, lighter periods. Other advantages with COC are decreased blood loss and uterine cramps, elimination of **mittelschmerz** (midcycle pain usually associated with ovulation), reduction of symptoms in many forms of benign breast disorders, and prevention of physiologic ovarian cysts. COC products also reduce the incidence of pelvic inflammatory disease (PID) and ectopic pregnancy, reduce endometrial and ovarian cancer risk, and reduce deaths from colorectal cancer. COC products do not reduce the incidence of sexually transmitted infections (STIs).

The goal of therapy is to identify the product that offers the best contraceptive protection while producing the fewest unwanted side effects as a result of either the estrogen or the progestin component. Note: the effectiveness of oral contraceptives can also be compromised by concurrent use of some medications (e.g., antibiotics) or herbal products (Herbal Alert 56-1).

Types of Combined Oral Contraception Products

There are three types of combined oral contraception pill products: monophasic, biphasic, and triphasic. These types of COC pills have also been categorized as "phasic" and "nonphasic" pills. The monophasics, or nonphasic pills, provide a fixed ratio of estrogen to progestin throughout the menstrual cycle. In biphasics, a phasic pill, the amount of estrogen is fixed throughout the cycle, but the amount of progestin varies; reduced in the first half to provide for some

HERBAL ALERT 56-1

St. John's Wort

- St. John's wort may decrease the level of contraceptive hormones in the bloodstream, reducing the effectiveness of CHC products. This may result in breakthrough bleeding and/or a spontaneous ovulation.
- Chasteberry extract is taken by women as an herbal supplement for premenstrual syndrome and menopausal symptoms. Chasteberry extract may alter contraceptive hormone levels in the body making them less effective. Chasteberry extract should be used with caution with CHC or hormone therapy.
- Other herbal remedies that may alter the effectiveness of contraceptive hormones include dong quai, black cohosh, and red clover.

proliferation of the endometrium and increased in the second half to promote secretory development of the endometrium. This simulates the normal physiologic process of menstruation while still inhibiting ovulation. Ortho-Novum 10/11 is an example of a biphasic pill (10 days of norethindrone 0.5 mg and EE 35 mcg followed by 11 days of norethindrone 1.0 mg and EE 35 mcg). The triphasics are the newest form of phasic COC products delivering low doses of both hormones with minimal side effects, including breakthrough bleeding. With triphasics, the amount of either estrogen or progesterone varies throughout the cycle in different ratios during three phases. Ortho Tri-Cyclen is an example of a triphasic pill that varies the dosage of progestin (7 days of norgestimate 0.180 mg and EE 35 mcg; 7 days norgestimate 0.215 mg and EE 35 mcg; 7 days of norgestimate 0.250 and EE 35 mcg). In Ortho Tri-CyclenLo, the progestin change is the same through the three phases as in Ortho Tri-Cyclen, but the dose of EE is lowered to 25 mcg, making this a low-dose pill option for women. Estrostep is an example of a triphasic pill that varies the dosage of estrogen (7 days of EE 20 mcg and norethindrone acetate 1.0 mg; 7 days of EE 30 mcg and norethindrone acetate 1.0 mg; and 7 days of EE 35 mcg and norethindrone acetate 1.0 mg). Ortho Tri-Cyclen, Ortho Tri-CyclenLo, and Estrostep have low androgenic activity and are FDA approved for the treatment of acne. Table 56-1 shows brand-name forms of COC, amounts of EE and type of progestin, and generic equivalents.

A new-generation progestin, Yasmin is a monophasic combination pill with 30 mcg of ethinyl estradiol and 3 mg of drospirenone (DSRP). While the progestin found in other combination oral contraceptives is structurally similar to androgens, drospirenone is the only progestin derived from spironolactone, which is structurally similar to progesterone. As noted, use of drospirenone may increase serum potassium, which can alter water and electrolyte balances in women using this product. Consequently, Yasmin is contraindicated in women with kidney, liver, or adrenal insufficiency and in women who require daily long-term treatment with any of the following medications: NSAIDs (e.g., ibuprofen) taken long-term and daily for arthritis or other diseases or conditions, potassium-sparing diuretics (e.g., spironolactone), potassium supplementation, ACE inhibitors (e.g., Accupril, Lotensin), angiotensin-II receptor antagonists (e.g., Cozaar, Diovan), and heparin.

Femcon Fe (norethindrone 0.4 mg and EE 35 mcg) and Generess Fe (norethindrone 0.8 mg and EE 25 mcg) are mint-flavored, chewable birth control pills for women who have difficulty swallowing pills. They can also be swallowed whole.

Withdrawal Bleeding

Most of the monophasic, biphasic, and triphasic combined oral contraception products are packaged in both 21-day tablet packs and 28-day tablet packs. In the 21-day tablet packs there are 21 days of active pills (pills that contain estrogen and progestin) followed by a 7-day "pill-free" period. A new pack of pills is started after the 7 day pill-free period. In the 28-day tablet pack, there are 21 days of active pills followed by 7 days of inert pills, called counters. The patient takes one pill daily and begins a new pack the day after the last counter pill is taken. During the hormone-free period (counters) or the 7-day pill-free period, the level of estrogen and progestin decreases allowing for a breakdown of the endometrial lining. This causes a pseudomenstruation known as **withdrawal bleeding** or withdrawal menses. The withdrawal bleeding is not a true menstrual period and the bleeding experienced by a woman can vary in amount and duration.

There are 28-day oral contraception pills that do provide medication during the 7-day hormone-free period. Estrostep Fe, Loestrin Fe 1.5/30, Loestrin Fe 1/20, Loestrin 24 Fe, and Generess Fe contain ferrous fumarate, an iron compound, to provide iron supplementation during the phase of withdrawal bleeding. This promotes healthy iron stores in women and protection against menstrual-associated iron-deficiency anemia. Another formulation is Mircette (desogestrel 0.15 mg and EE 20 mcg), which supplies 2 inert pills and 5 pills with 10 mcg of ethinyl estradiol during the counter phase. The use of low-dose estrogen during the "inert" phase of the pill cycle provides a greater degree of ovarian suppression. Another benefit may be the decrease in headaches associated with estrogen withdrawal. Patients who experience headaches associated with the menstrual cycle may benefit from Mircette.

Withdrawal bleeding periods are scheduled monthly to mimic a normal 28-day menstrual cycle; however, researchers have established that a monthly episode of withdrawal bleeding is not necessary to maintain a healthy uterus. There are now FDA-approved formulations of estrogen-progestin combination pills that do one of the following: (1) shorten the period of withdrawal bleeding by extending the number of active pills and decreasing the number of inert pills in the 28-day pill cycle, (2) decrease the number of withdrawal menses per year by having 81 to 84 continuous days of active pills and 7 days of less active pills, resulting in four withdrawal menses per year, or (3) eliminate withdrawal bleeding altogether by continuous oral administration of active pills.

TABLE 56-1 ORAL CONTRACEPTION COMBINATION PRODUCTS: LISTED BY TYPE OF PROGESTIN

PRODUCT TYPE	ESTROGEN (mcg)	PROGESTIN (mg)
Combination Monophasic Products Containing Norethindrone and EE

Extended-Cycle COC Products

Loestrin 24 Fe is a 24-day monophasic hormonal regimen of 20 mcg of ethinyl estradiol tablets and 1 mg of norethindrone acetate, plus 4 ferrous fumarate tablets. It provides 24 days of active hormonal therapy and 4 days of hormone-free pills containing an iron supplement. The active pill days are extended, while the number of inert pill days are reduced, which shortens the period of withdrawal bleeding that the patient will experience. The shorter period of hormone-free tablets increases the contraceptive's efficacy.

Like Yasmin, Yaz (drospirenone 3 mg and EE 20 mcg), another extended-cycle combined hormone pill, contains the progestin drospirenone (DRSP), a spironolactone analogue with antimineralocorticoid properties. The 24-day active hormone pill regimen of Yaz combined with the 30-hour half-life of drospirenone results in less hormonal fluctuation between cycles, compared with traditional oral contraceptives with 21 days of active pills and 7 days of placebos. Preclinical studies indicate that drospirenone also provides an antiandrogenic effect, which means that it counteracts the effects of male hormones in the body. Yaz is FDA approved for the treatment of premenstrual dysphoric disorder (PMDD) as well as acne. It has the same serum potassium precautions as Yasmin. As with Loestrin 24 Fe, women experience a shorter and lighter withdrawal bleeding period with increased ovarian suppression.

Beyaz, with 24 pills containing 3 mg DSRP, 20 mcg of EE, *and* 0.451 mg of levomefolate calcium (a folic acid supplement), and with 4 pills of 0.451 mg of levomefolate calcium in the inert phase, is also available in the United States. Produced by the same pharmaceutical company as Yasmin and Yaz, Beyaz contains DSRP and has the same precautions as Yasmin and Yaz; however, it also contains a form of folic acid throughout the pill cycle promoting healthy folic acid levels for reproductive-age patients. Therefore, Beyaz may help prevent open neural tube defects, should the patient plan to become pregnant. Beyaz is also approved for use in the treatment of PMDD. In April 2012, the FDA issued an updated warning that women taking combined oral contraception products containing drospirenone may have a twofold increased risk for venous blood clot formation compared with women taking CHC products that do not contain DSRP. Women considering a contraceptive product containing DSRP should be made aware of this risk.

Continuous Dosing COC Products

Seasonale (Jolessa) is a continuous dosing combined hormone contraception pill. The 91-day regimen includes 84 days of active pills and 7 days of inert pills. Seasonale (Jolessa) causes withdrawal bleeding to occur just four times per year. The active hormone pills in Seasonale (Jolessa) contain 30 mcg of ethinyl estradiol (EE) and 0.15 mg of levonorgestrel (LNG). Seasonale (Jolessa) is the drug predecessor of Seasonique.

Seasonique is a continuous dosing contraception pill that causes withdrawal bleeding four times per year. It cycles 84 days of tablets that contain 30 mcg of EE and 0.15 mg of LNG, followed by 7 days of tablets that contain 10 mcg EE. During the 7 days of low-dose estrogen pills, women usually experience withdrawal menses. However, by adding very low levels of estrogen in the 7-day "break" period, instead of inert pills, Seasonique provides additional benefits such as a reduction in breakthrough bleeding. LoSeasonique contains 20 mcg of EE and 0.1 mg of LNG, followed by 7 days of 10 mcg of EE, offering a very low-dose continuous CHC product option. Users of extended-cycle birth control pills are more likely to experience bleeding or spotting between periods. The continued progestin dose causes extreme atrophy of the endometrial lining. The atrophic endometrium subsequently breaks down, and the patient experiences uterine bleeding in an irregular pattern.

Lybrel is the first continuous dose combined oral contraception pill to be FDA approved. Lybrel comes in a 28-day pack and contains 20 mcg of EE and 90 mcg of LNG. Lybrel is taken daily and continuously without interruption for withdrawal menses.

Although these products are more commonly known for their contraceptive value, women with menstrual disorders such as menorrhagia (heavy periods), **metrorrhagia** (irregular bleeding between periods, usually heavy), endometriosis, dysmenorrhea, premenstrual syndrome (PMS), and physiologic ovarian cyst formation may benefit from continuous-cycle COC products because of their ability to suppress ovarian function and limit uterine bleeding.

Ortho-Evra Transdermal Patch

The Ortho-Evra patch is a weekly form of combined hormone contraception, consisting of 750 mcg of ethinyl estradiol and 6 mg of the progestin norelgestromin (NGMN) delivered through a transdermal system. It is a thin plastic patch placed on the skin of the buttocks, stomach, upper outer arm, or upper torso. The patch is placed once a week for 3 weeks in a row. The fourth week is patch-free to allow for withdrawal bleeding. It should be placed on clean, dry skin; placement on or near the breasts should be avoided because of the estrogen component. Site of patch placement should be rotated to avoid skin irritation. If the patch partially or completely detaches from the skin, a new patch should be placed. When used correctly, the patch protects against pregnancy on a monthly basis. The theoretical and typical use effective rate for the patch is 99.3% and 92%, respectively, making it 92% to 99.3% effective at preventing pregnancy.

The patch works in a similar manner to COC pills by inhibiting ovulation, thickening cervical mucus to prevent sperm penetration, and preventing a fertilized egg from implanting in the uterus. The patch avoids the first-pass through the liver effect. Advantages include not having to remember to take a pill daily. As with combined oral contraception products, the ability to become pregnant returns quickly when its use is discontinued. There is less menstrual flow and cramping, acne, iron-deficiency anemia, excess body hair, premenstrual symptoms, and vaginal dryness with the patch. As with COC pills, the patch reduces the risk for ovarian and endometrial cancers, PID, breast cysts, ovarian cysts, and **osteoporosis** (loss of bone mass predisposing the patient to fractures). With the patch, there are fewer occurrences of ectopic pregnancy.

Disadvantages of the patch include skin reaction at the site of application, menstrual cramps, and a change in vision or the inability to wear contact lenses; it is not as effective for women who weigh more than 198 lb. In 2005, the FDA approved an addition to the labeling of the Ortho Evra transdermal patch stating that it exposes patients to higher levels of estrogen. In theory, this indicated that women using the patch for contraception may be at an increased risk for venous thromboembolism (VTE). With CHC pills, peak serum estrogen levels are reached rapidly after ingestion and then steadily decline. With the patch, peak serum estrogen levels when reached are 25% less than in women taking the pill, however, these peak levels remain throughout the patch placement week, and then decline, exposing women to 60% more estrogen than with the CHC pill. Ongoing research is necessary to demonstrate exact risk for VTE as well as other cardiovascular complications (particularly heart attack and stroke) in women using the Ortho Evra transdermal patch. Women being prescribed the transdermal route of CHC should be notified of potential risks, and the patch should be used with extreme caution in any patient with increased risk for VTE. Women who are older than 35 years and smoke should not use the Ortho Evra transdermal patch. Other side effects include temporary irregular bleeding, weight gain or loss, breast tenderness, and nausea.

NuvaRing Transvaginal Contraception

NuvaRing is a 2-inch–diameter flexible indwelling ring inserted into the vagina. It is nonbiodegradable, transparent, and colorless to almost colorless. NuvaRing releases 15 mcg of EE and 120 mcg of the progestin *etonogestrel* per day, similar to the quantities of estrogen and progestin found in lower-dose COC products. Etonogestrel is a biologically active metabolite of desogestrel and a new-generation progestin, which may be associated with an increased risk for VTE. Also, NuvaRing has an extended placement schedule, which may mean that the estrogen peak rate, although lower than that of CHC pills, remains sustained longer because of the 3-week ring placement. As with the Ortho Evra transdermal patch, this may expose the patient to higher levels of estrogen. Studies have been inconclusive, and the FDA has placed no additional warning on NuvaRing.

Theoretical effectiveness and typical effectiveness rates are 98% and 92%, respectively, reflecting a rate similar to other leading CHC contraceptive methods. The patient inserts the ring during the first 5 days of the menstrual cycle. She then removes the ring after 3 weeks, remains "ring-free" for 1 week (for withdrawal menses), and then inserts a new ring. Backup contraception is recommended during the first 7 days after the first ring is placed. During this time, the hormones reach an appropriate protective level. After this, contraceptive effects are expected to be continuous provided the ring is correctly inserted. Correct insertion involves placing the ring into the middle or upper third of the vagina. Unlike the diaphragm, it does not need to be placed near or over the cervix. It is the close proximity of the ring to the vaginal mucosa that causes absorption of steroid hormones to occur. The ring remains in place during intercourse, tampon use, or the administration of intravaginal medications. If the ring slips out, it can be rinsed with lukewarm water and reinserted into the vagina. It should be reinserted within 3 hours after becoming dislodged. If the ring remains out for more than 3 hours, additional contraception is required until the ring has been in place for 7 days. Possible side effects include vaginal discharge, irritation, or infection. Other associated risks are the same as for low-dose COC products and are increased in patients who smoke.

PROGESTIN-ONLY CONTRACEPTION PRODUCTS

Progestin-only contraception products do not contain estrogen. The estrogen component of contraceptives increases the risk of circulatory disorders; therefore, these products allow contraception to be available for women who cannot take estrogen-progestin combination products. Advantages of progestin-only contraception products include relative safety, ease of use, spontaneity of sexual intercourse, and reversibility. However, because the estrogen component is missing, these products have a higher incidence of irregular bleeding and spotting, as well as the possibility of depression, mood changes, decreased libido, fatigue, and weight gain. Progestin-only contraception products do not protect women against STIs. Women who cannot take estrogen but may be candidates for progestin-only contraception products include patients with personal or strong family history of VTE or heart disease, breastfeeding patients, smokers older than 35 years of age, and women with uncontrolled hypertension. Women who have an untoward response to estrogenic effects such as chloasma, migraine headaches, or changes in lipid profiles may also be candidates for progestin-only products. Progestin-only contraceptive methods are available in oral, intramuscular, subcutaneous, and implantable routes of delivery.

Progestin-Only Oral Contraception Pill

The progestin-only oral contraception pill (POP), called the *minipill,* has four mechanisms of action: (1) alteration in cervical mucus, making it thick and viscous, which blocks sperm penetration; (2) interference with the endometrial lining, which makes implantation difficult; (3) decreased peristalsis in the fallopian tubes, slowing the transport of ovum; and (4) in approximately 50% of cycles, interference with the LH surge inhibiting ovulation. POPs that contain 0.35 mg of norethindrone as the progestin include Micronor, Nor-QD, Aygestin and their generic equivalents, Errin, Jolivette, Nora-BE and Camila. Ovrette is a POP that contains 0.075 mg of norgestrel. The minipill is taken continuously, without a break for withdrawal bleeding. Patients should be instructed to take the minipill daily, within a 3-hour window.

The theoretical effective and typical use effective rates for the first year of use are similar to that of COC products even though patient adherence to dosage schedule with POPs is more specific. It takes 4 to 6 hours for the progestin to thicken the cervical mucus to prevent sperm penetration, and the duration of the effect of the progestin on cervical mucus lasts just over 24 hours. Risk for pregnancy will increase if a patient misses a pill because POPs do not suppress the release of follicle-stimulating hormone (FSH) and LH to the same degree as COC products. If the minipill is taken more than 3 hours late, a backup contraceptive method should be used for 48 hours. There are no placebo pills in a pack of progestin-only pills. All 28 pills contain active hormones, so the patient continuously takes one active pill daily. Because the endometrial lining is altered, an increase in the amount of irregular bleeding is noted.

Depo-Provera

Depo-Provera is a highly effective, long-acting injectable progestin in the form of depot-medroxyprogesterone acetate (DMPA or MPA), with a theoretical and typical use efficacy rate of 99% and 97%, respectively. This makes Depo-Provera, the brand name for DMPA, one of the most effective hormonal methods of contraception at 97% to 99%. It appeals to women because of its confidentiality of use and convenient dosing schedule. DMPA is popular for adolescents for these reasons. Depo-Provera is administered in a flexible dosing schedule, every 11 to 13 weeks. The mechanism of action of Depo-Provera relies on the progestational activities: thickening of the cervical mucus, thinning of the uterine endometrium, and decrease in fallopian tube motility. Because the progestin in Depo-Provera reaches a higher circulating level than with POPs, DMPA inhibits both FSH and LH secretion from the anterior pituitary gland. This results in both **anovulation** (lack of ovulation) and amenorrhea. Because FSH and LH secretion is inhibited, any formation of a dominant follicle is prohibited and the production of estrogen in the body is greatly decreased. The patient experiences a hypoestrogen state, which can affect bone mineral density (BMD).

The depot-medroxyprogesterone vial or prefilled syringe should be vigorously shaken just prior to administration to ensure a uniform medication suspension. Depo-Provera, 150 mg, is given by deep IM injection into the gluteal, ventrogluteal, or deltoid muscle. Depo-Provera is more effective if given in the ventrogluteus muscle, although research has not supported this. The site should not be massaged after injection. The injection site is documented so that sites can be rotated. The patient is given a personalized calendar for subsequent doses and should return for another injection within 13 weeks. If the patient is late for her injection (13 weeks and 1 day), pregnancy should be ruled out before she receives another injection.

As with oral contraceptives, there is no protection against STIs. There is concern that MPA may cause a loss of bone mineral density, and results of research studies are still controversial. Most recent evidence suggests that at least partial or full recovery occurs in BMD of the spine, with partial recovery occurring in BMD of the hip after the patient discontinues Depo-Provera use. Until ongoing research is conclusive, the FDA recommends that Depo-Provera be discontinued after 2 years of continuous use unless other methods of contraception are inadequate. Many professional provider organizations agree that the concerns of the 2-consecutive-year limit given by the FDA and the BMD effects of DMPA should not prevent the practitioner from considering the benefit-risk ratio for each individual patient. The American College of Obstetricians and Gynecologists (ACOG) states in a committee opinion that "the possible adverse effects of DMPA must be carefully balanced against the significant personal and public health impact of unintended pregnancy." The benefits, risks, and alternatives, as well as the prevention of bone mineral density loss while on Depo-Provera, must be discussed with the patient before administration of the product.

Women taking Depo-Provera should be instructed to increase calcium and vitamin D intake to the daily recommended allowance for their age, as well as to participate in regular weight-bearing exercises. Depo-Provera is safe to receive immediately postpartum. Women can breastfeed while using this contraceptive without affecting milk supply. The most common side effects include initially irregular uterine bleeding or spotting. Menstruation may cease about 1 year after starting Depo-Provera. In addition, Depo-Provera has been shown to cause progressive weight gain in some women. Other side effects include breast tenderness and an increase in depression. The drug is contraindicated in cases of undiagnosed vaginal bleeding and known or suspected pregnancy. Caution should be used in giving DMPA postpartum in women who are at risk for or have a history of postpartum depression.

Depo-subQ Provera 104 is available as an injectable suspension. It contains the same progestin in Depo-Provera, MPA, but it is administered in a subcutaneous injection. The dose is 104 mg/0.65 mL, and it is given to women every 11 to 13 weeks. Depo-subQ Provera 104 has the same mechanism of action, benefits, and risks as Depo-Provera, and women should be counseled about the potential loss of bone mineral density. Depo-Provera and Depo-subQ Provera 104 have a slower return to fertility than other hormonal methods of contraception.

Implantable Progestins

Nexplanon is a single-rod device containing 68 mg of the progestin etonogestrel; it is placed in the same location as Implanon. It is bioequivalent to Implanon, lasting for up to 3 years and removed in the same manner. Training is also provided for practitioners for the insertion and removal of Nexplanon. The difference is that Nexplanon contains barium, a radio-opaque substance that can help locate the device on two-dimensional x-ray, ultrasound, magnetic resonance imaging (MRI) and computed tomography (CT) scanning if necessary. Also, the device comes in a new, preloaded application system that will reduce insertion errors. Nexplanon may not be as effective in women who have a BMI greater than 30 (obese) or are on medications that induce liver enzymes. Patient education will be the same as that for Implanon.

Theoretical and typical effectiveness rates for implantable progestins are the same, at 99.6%.

Pharmacokinetics: Estrogen-Progestin Combination Products EE is rapidly absorbed orally. It undergoes significant first-pass metabolism and elimination via the liver. Mestranol is converted in the liver to EE, which is 97% to 98% bound to plasma proteins. The half-life varies from 6 to 20 hours. Excretion is via bile and urine in a conjugated form. Some enterohepatic recirculation occurs. The steroid hormones in NuvaRing are absorbed through the vaginal mucosa into veins that flow directly into the inferior vena cava. The steroid hormones pass through the circulatory system and directly to the uterus, causing a "first-uterine" pass. The etonogestrel in NuvaRing has a bioavailability of 100% when administered vaginally, compared with EE bioavailability of 55%. With the Ortho-Evra patch, absorption is through the skin into venous circulation, also bypassing the hepatic portal system. Avoiding the liver first-pass effect decreases adverse enterohepatic reactions. The norelgestromin in the patch binds to albumin. Levels of serum steroid hormones in the patch reach constant levels of contraceptive efficacy within 48 hours. It is suggested that the alternative routing may increase the incidence of venous thromboembolitic events because peak levels of serum EE, although lower than that of oral ingestion, remain in the body for a longer duration. Alternative routing may decrease the incidence of irregular bleeding and nausea (NuvaRing only). Also, the avoidance of first-pass through the liver has the potential to decrease adverse drug interactions. Serum hormone levels are rapidly reached and blood levels do not fluctuate as much as is seen with oral contraception products.

Pharmacokinetics: Progestin-Only Products Progestins are also well absorbed orally. Peak plasma levels occur from 0.5 to 4 hours after ingestion, depending on the particular compound. Norethynodrel and ethynodiol diacetate are converted to norethindrone. Levonorgestrel is bioavailable and does not undergo first-pass liver metabolism; norethindrone undergoes first-pass metabolism and is 65% available. The progestins are bound to plasma proteins and to sex-hormone–binding globulin. The half-life of norethindrone varies from 5 to 14 hours; the half-life of levonorgestrel is 11 to 45 hours. MPA is without androgenic and estrogenic activity. Depot-MPA is crystalline suspension. DMPA is not soluble in lipid or water. The crystalline deposits in body tissues and then is reabsorbed. Depo-Provera provides higher peak levels of progestin than POPs and Implanon. Once injected, the levels of MPA increase for 3 weeks, and then remain stable. MPA is not detected in the blood between 120 and 200 days after injection. Nexplanon is a sustained-release system that releases progestin at a level of 60 to 70 mcg/day during the first six weeks after insertion and 35 to 45 mcg/day during the first year. This decreases to 30 to 40 mcg/day after 2 years of implantation and 25 to 30 mcg/day by the end of the third year. Once the rod is inserted, effective contraceptive levels are reached within 8 hours.

Start Date and Dosing Schedule

There are three ways to implement the start of hormonal contraception products unless otherwise indicated by the pharmaceutical company manufacturing the product.

With the *first-day start method,* the contraception product is initiated on the first day of menstruation, or the first day a women experiences bleeding. The first day of bleeding is day 1 of the menstrual cycle. Days are then counted 2, 3, 4, 5, 6, and so on, until the first-day bleeding begins again, usually around day 28. Most methods of contraception can be safely started on day 1 through day 5 of the menstrual cycle, when it is less likely that the patient has an early undiagnosed pregnancy. No backup method of contraception is needed when the product is started on the first through fifth day of menstruation. (A backup method is a second method of contraception that is used until the primary method reaches its peak level of contraceptive effectiveness.) Usually this is a barrier method, such as a condom or diaphragm.

Many products require a *Sunday start* (patient starts the tablets or patch on the Sunday after the first day of menstruation). If menstruation actually starts on Sunday, the patient starts her tablet or patch on that day. The Sunday start aids a woman in remembering the first day of her contraception cycle. If a patient starts her method of contraception later than day 5 of her menstrual cycle, a backup form of contraception should be used for 7 days.

The *quick-start method* of initiating contraception starts the method on the day the patient receives the prescription regardless of where she might be in her menstrual cycle. This method increases patient compliance and resolves the risk for becoming pregnant while waiting for a menstrual period to begin to start the method. Pregnancy should be ruled out prior to the quick-start method, but there is a risk that the patient could have an early pregnancy undetectable by screening. A backup method of contraception must be used for 7 days if the quick-start method is employed after the first 5 days of the menstrual cycle. Both estrogen-progestin and progestin-only contraception methods are contraindicated in pregnancy (Category X). *Nonetheless, there is no evidence of fetal risks associated with these medications when inadvertently used in pregnancy.* If the patient does not get a withdrawal menses when planned, a pregnancy test is administered.

Special Considerations

Depo-Provera and NuvaRing should be started within the first 5 days of the menstrual cycle. (Sunday start and quick-start methods are off-label.) Seasonale (Jolessa) and Seasonique use a Sunday start only. Lybrel uses a first-day start. If the patient is on a 21-day combined oral contraception regimen, she restarts her next pack following the 7-day break whether or not her bleeding has stopped. With 28-day packs, a pill is taken daily without stopping regardless of bleeding pattern. Usually, withdrawal menses occur in a cyclic fashion. In biphasic and triphasic preparations, the day 1 pill is clearly marked and the tablets are taken in the order noted. A difference in the color of the tablets delineates the change in dose of estrogen or progestin through the phases. With the POP, a pill is taken daily without a break. To increase effectiveness, all oral contraception pills should be taken at the same time daily. With the POP, women should strictly adhere to this instruction.

Missed Doses

Table 56-2 presents guidelines for missed doses of oral contraceptives. All patients who are prescribed oral methods of contraception should also be instructed in the use of emergency contraception.

Contraindications

Not every patient is a candidate for use of CHCs. Box 56-1 lists contraindications to CHC use.

TABLE 56-2 **GUIDELINES FOR MISSED DOSES OF ORAL CONTRACEPTIVES**

MISSED DOSE	RECOMMENDATIONS
Combination Products	
One tablet	Take tablet as soon as realized. Take next tablet as scheduled.
Two tablets	Take 2 tablets as soon as realized and 2 tablets the next day Use backup method of contraception for rest of cycle.
Three tablets	Discontinue present pack, and allow for withdrawal bleeding. Start new package of tablets 7 days after last tablet taken. Use another form of contraception until tablets have been taken for 7 consecutive days.
Progestin-Only Products	
One or more tablets	Take tablet as soon as realized, and follow with next tablet at regular time, PLUS use backup method of contraception for 48 h

h, Hour.

BOX 56-1 CONTRAINDICATIONS FOR CHC PRODUCTS

Absolute Contraindications

- Pregnancy (known or suspected)
- Venous thrombosis history or risk factors
- Vascular disease, including coronary artery disease and CVA and past or current history of DVT or pulmonary embolism
- Liver disease; including cirrhosis, viral hepatitis, and benign or malignant liver tumors
- Undiagnosed vaginal bleeding or known or suspected endometrial cancer
- Breast cancer
- Tobacco use of >15 cigarettes per day in patient older than 35 years of age

Cautious Use

- Hypertension with associated vascular disease
- Hypertension with blood pressure >160/100
- Hyperlipidemia
- Diabetes mellitus complicated by neuropathy, retinopathy, nephropathy, or vascular disease
- Diabetes mellitus >20 year duration
- Postpartum <3 weeks
- Lactation <6 weeks
- Older than 35 years of age and smokes <15 cigarettes/day
- Hypercoagulation disorders
- Prolonged immobility
- Use of drugs that affect liver enzymes (e.g., anticonvulsants, rifampin)

CVA, Cerebrovascular accident; >, greater than; <, less than.

Drug Interactions

The effectiveness of some drugs is impaired by CHC products; other drugs impair the effectiveness of CHC and progestin-only products. Box 56-2 shows drugs that may have interactive effects with CHC products. Patients receiving low-dose formulations of oral contraceptives need to be particularly cautious about potential interactions. If a patient is on a medication that affects estrogen absorption or metabolism, an estrogen-progestin oral contraception product with a higher dose of EE or mestranol may be prescribed.

Potential Side Effects and Adverse Reactions

It is accepted by health care providers that the risks associated with CHC products and all other methods of hormonal contraception are much less than the risks associated with pregnancy. This is especially true if the patient does not exhibit the contraindications listed in Box 56-1. In most cases, the benefits of any contraceptive method usually outweigh the risks when using a benefit-risk ratio to determine patient eligibility.

Benefit-risk ratio is partially determined by the risk related to the particular contraceptive method as compared to the risk pregnancy poses for the patient. Also included in the benefit-risk ratio is consideration of age, smoking status, allergies and medications, health histories and physical assessments, as well as lifestyle patterns and changes of the patient. These considerations determine patient selection or nonselection for the method as well as continuing or discontinuing a method of contraception.

Most of the untoward side effects are related to differences in the estrogen-progestin ratio of the products and the patient's response to these differences. Side effects primarily caused by an excess of estrogen include nausea, vomiting, dizziness, fluid retention, edema, bloating, breast enlargement, breast tenderness, chloasma (slightly more in dark-skinned patients on higher-dose tablets who are exposed to sunlight), leg cramps, decreased tearing, corneal curvature

BOX 56-2 DRUGS THAT INTERACT WITH CHC PRODUCTS

Drugs That Decrease the Effectiveness of CHC

Use a higher-dose pill or an alternative form of contraception (if the medication is continuous.) Use a backup method for the duration of treatment plus 7 days (if medication is short-term).

Anticonvulsant Medications

- carbamazepine (Tegretol)
- Hydantoins: ethotoin, mephenyltoin, phenyltoin
- succinimide

Antituberculin Medications

- rifampin (Rifadin)

Antifungal Medications

- griseofulvin (Gris-PEG)

Antibiotics

- amoxicillin
- ampicillin (Amoxil)
- doxycycline (Vibramycin)
- metronidazole (Flagyl)
- minocycline (Minocin)
- neomycin (Neo-Fradin)
- nitrofurantoin (Macrobid)
- penicillin
- tetracycline (Sumycin)

Barbiturates

- phenobarbital (Luminal)
- primidone (Mysoline)

Hypnotics and Sedatives

- Benzodiazepines

Migraine Drugs

- topiramate (Topamax)

Drugs That May Increase CHC Activity

- acetaminophen (Tylenol)
- ascorbic acid (vitamin C)
- fluconazole (Diflucan)

Other Drug Interactions

- An alternative method of contraception is necessary.
- Anticoagulants: CHC products increase clotting factors and decrease the effectiveness of anticoagulants.
- Anticonvulsants: CHC products may increase risk for seizure.

alteration, visual changes, vascular headache, and hypertension (in about 1% to 5% of previously normotensive patients within the first few months).

Side effects primarily caused by estrogen deficiency include vaginal bleeding (breakthrough bleeding, especially in the first few cycles after starting therapy) that lasts several days (usually during days 1 to 14); **oligomenorrhea** (very scant periods), especially after long-term use; nervousness; and **dyspareunia** (painful sexual intercourse) secondary to atrophic vaginitis.

Side effects primarily caused by an excess of progestin include increased appetite, weight gain, oily skin and scalp, acne, depression, vulvovaginal candidiasis (vaginitis from the yeast microbe candida, excess hair growth, decreased breast size, and amenorrhea after cessation of use (1% to 2% of patients).

Side effects primarily caused by progestin deficiency include dysmenorrhea, bleeding late in the cycle (days 15 to 21), heavy menstrual flow with clots, or amenorrhea. There may also be changes in laboratory values, including thyroid and liver function, blood glucose, and triglycerides.

The CHC pill may increase the vascularity of the cervical epithelium, extend the area of cervical ectopy, and alter certain immune parameters. Advise pill users to use male or female latex or polyurethane condoms unless they are confident that both partners are free of HIV and other STIs.

Adverse reactions of a more severe nature include cardiovascular and carcinogenetic risks.

Cardiovascular. There is an increased risk for hypertension (usually seen within 3 months after initiating the CHC method in women with preexisting risk) and arterial blood clot complications such as myocardial infarction, pulmonary embolus, and cerebrovascular accident in women using CHC methods as compared to women who are not on CHC methods of contraception. However, in terms of absolute risk for adolescents and women, the rate of dangerous complications from hormonal methods of contraception is extremely low because women younger than 50 years rarely experience heart attack or stroke. The risk for hypertension in women younger than 35 years is also low. Hormonal methods of contraception that contain drospirenone or etonogestrel may double a woman's risk for blood clots in the veins in the form of venous thromboembolitic events. Cardiovascular risks are increased in women older than 35 years who smoke, women older than 45 years, and women with hypertension that is undiagnosed or uncontrolled by medication.

Carcinogenesis. Long-term use of CHC products may increase the risk for breast cancer in younger women, but the risk is minimal. Breast cancer risk returns to normal 10 years or more after discontinuing CHC products. There is an increased risk for benign liver tumors. Risk for cervical cancer is slightly increased, thought to be because CHC methods change cervical epithelium, making it more susceptible to the high-risk human papillomavirus (HPV) pathogen and because condoms may be used less frequently in prevention of STIs. Women who use hormonal methods of contraception have a greatly reduced risk for ovarian and endometrial cancer, and the protective effect is directly related the duration of time the method is used.

Nursing Process

Patient-Centered Collaborative Care

Hormonal Methods of Contraception

Assessment

- Obtain a record of the patient's drug, supplement, and complementary and alternative medicine (CAM) use.
- Obtain baseline vital signs including temperature, pulse, respirations (TPR), BP, weight, and height. Calculate body mass index (BMI). Report abnormal findings.
- Obtain a complete menstrual history including age at menarche, menstrual pattern, cycle length, duration, and amount of bleeding and the first day of the last menstrual period (LMP). A detailed history of the menstrual cycle in reproductive-age and climacteric women should be considered as another vital sign.
- Determine pregnancy status.
- Obtain a family medical history specific to contraindications for CHC and progestin-only product use.
- Obtain family history of premenopausal breast cancer.
- Assess for domestic violence, intimate partner violence, and past or recent sexual abuse/assault.
- Obtain a medical history, assessing for history of allergies to medications, smoking, hypertension, and contraindications to CHC products listed in Box 56-1.
- Obtain a complete obstetrical and gynecologic history including gravida, parity, pregnancy termination and pregnancy loss, age of first and last pregnancy, time frame between pregnancies, complications during pregnancy birth and postpartum, genetic anomalies and health of children, time frame since last Papanicolaou (Pap test), history of abnormal Pap testing, history of gynecologic and/or sexual infections, gynecologic problems and/or surgeries, and gynecologic anomalies.
- Obtain a complete sexual history including sexual expression practices, sexual risk practices, history of STIs and treatment, and past or present sexual abuse and/or assault.
- Recognize need for periodic reassessment of baseline data and side effects. Most patients should be seen in 1 to 3 months after beginning contraceptive regimen.

Nursing Diagnoses

- Deficient knowledge regarding reproduction, reproductive health, and self-care
- Decisional conflicts related to contraception methods
- Decisional conflicts with partner and contraceptive method choice and/or family planning
- Deficient knowledge regarding contraceptive method(s) and appropriate use of method

- Fear related to contraceptive method side effects
- Risk for infections related to unprotected intercourse
- Ineffective expression of sexuality related to fear of pregnancy (and/or method failure)
- Decisional conflicts related to discrepancy between cultural and/or religious beliefs and contraceptive method choice

Planning

- Patients with contraindications to hormonal contraception will be risked out through patient selection and determination of benefit-risk ratio.
- Patient will understand the difference between estrogen-progestin combination products and progestin-only contraception products and their various routes of administration.
- Patient will verbalize understanding the bleeding patterns associated with both types of products by reporting menstrual changes that occur.
- Patient will choose a contraceptive method suitable for her lifestyle and health status.
- Patient will understand the benefits, risks, and alternatives to the method chosen through the BRAIDED method (see below).
- Starting method, dosing schedule, and use of contraceptive method chosen will be explained at patient's level of understanding.
- Explain ACHES and provide contact information (see Side Effects section further on in this section).
- Patient will take oral contraceptives as prescribed and report side effects that occur.
- Patient will place Ortho-Evra patch as prescribed and will report adverse side effects that occur.
- Patient will demonstrate and report comfort with vaginal placement of NuvaRing and report adverse side effects that occur.
- Patient will be aware of specific scheduling needed for progestin-only pills.
- Patient will understand initiation and calendaring of Depo-Provera injection, scheduling, need for weight-bearing exercises, and calcium supplementation.
- Patient will be given time to ask questions related to reproductive health, method choice, benefits, risks and alternatives, and method use.
- Follow-up appointment will be scheduled as needed.

Nursing Interventions

- Separate personal views from those of the patient regarding contraception and use of specific products.
- Address patient's misconceptions, and provide factual, evidence-based information.
- Encourage informed consent for contraceptive method through BRAIDED method: discuss *Benefits* (advantages, positive aspects, and both theoretic and actual effective rates of method), *Risks* (dangers, complications, disadvantages, and failure rates), *Alternatives* (other contraception options available to patient), *Inquiries* (opportunity for patient to ask questions about options proposed), *Decision* (deciding on a method with opportunity to change decision as needed), *Explanation* (health care teaching specific to method chosen), and *Documentation*.
- Use health teaching to encourage effective use of contraceptive method chosen.
- Ensure that patient understands start date, continuation of medication, and appropriate follow-up.
- Recognize that a percentage of patients on hormonal contraceptives will abandon method within 1 year; plan to provide the patient with alternatives and to seek care with a qualified health care provider prior to discontinuing any method of contraception.
- Non-nursing mothers can begin combination hormone contraception 4 to 6 weeks postpartum, regardless of whether or not menstruation has spontaneously occurred. Some sources indicate that a CHC method can be initiated as early as 3 weeks postpartum.
- Non-nursing and nursing mothers can begin Depo-Provera immediately postpartum if there is no increased risk for postpartum depression. POPs can be started at 4 to 6 weeks postpartum.
- Recognize that combined hormonal methods of contraception may decrease breast milk in patients who are currently breastfeeding. (CHC products can be used by breastfeeding mothers; however, CHC methods should be initiated after breastfeeding is well established. This is usually 2 to 3 months after the birth, with some sources stating that 6 weeks is sufficient.)

Patient Teaching

General

- Remind patient that these drugs should be used only under direction of a qualified health care provider.
- Advise patient that concurrent use of some drugs and herbal products decreases effectiveness of hormonal contraceptives. Patient should use a second form of contraception during use of these medications and herbal supplementations and possibly as long as 7 days after discontinuing counteracting medication.
- Patient will understand that hormonal methods of contraception do not prevent transmission of STIs or the pathogen that causes HIV infection and AIDS. If patient is at risk for STI or HIV infections, condoms should be used concurrently with CHC method, and safe-sex practices should be discussed. Inform patient of proper condom use.

Safety

- Counsel patient not to smoke tobacco because of increased cardiovascular risks.
- Advise patient to use barrier method of contraception as needed during first 7 days of contraception use if method is started 5 days or more after first day of

menstrual period. Instruct how to use barrier method properly.

- Teach patient about how to manage missed pills (see Table 56-2). Provide instruction for missed POPs, patch, ring, and injection methods. Review instructions for emergency contraception.
- Advise patient to report any effects from hormonal contraception to provider so therapy can be adjusted to suit her needs. Encourage her not to discontinue use of the method until an adequate trial time frame has been completed, which should be at least 3 to 6 months.
- Counsel patient that health care professionals should be advised of CHC use before surgery in which immobilization for an extended period may be needed.
- Encourage patient to report any irregular bleeding or BTB. A change in dose or type of hormonal contraceptive method may be advised.
- Advise patient to always report that she takes hormonal contraceptives when seeing a health care provider because of possible synergistic or antagonistic responses to other medications and therapies.
- Advise nursing mothers that the use of CHC products may decrease quantity and quality of breast milk.

Side Effects

- Advise patient that rare but serious side effects can occur, including VTE, myocardial infarction, cerebrovascular accident, and retinal vein thrombosis
- Teach patient the acronym ACHES for reporting symptoms of dangerous cardiovascular side effects to health care provider: *A*bdominal pain (severe); *C*hest pain or shortness of breath; *H*eadaches (severe), dizziness, weakness, numbness, speech difficulties; *E*ye disorders including blurring or loss of vision; *S*evere leg pain or swelling in calf or thigh.
- Encourage patient to notify health care provider immediately if she experiences any of these symptoms.
- Advise patient that her menstrual flow may be less in amount and duration because of thinning of endometrial lining with CHC and progestin-only products.
- Advise patient of menstrual changes that can occur at start of combined estrogen-progestin contraception products, when changing types of hormonal contraception products, and with progestin-only products.
- Determine whether or not patient wears contact lenses, and discuss how to handle dry eyes caused by decreased tearing and alterations in the shape of the cornea.
- Counsel patient who experiences post-CHC amenorrhea that 95% of women have regular periods within 12 to 18 months. Advise her that those who participate in endurance fitness activities may have increased post-CHC amenorrhea.
- Advise patient of a possible decrease in libido caused by an alteration in vaginal secretions and decreased levels of testosterone.
- Ensure that patient understands ability to return to fertility after discontinuing a hormonal contraception product and time frame in which pregnancy can be expected.
- Ensure a safe transition between contraceptive methods if a change in method is desired.

Skill

- Teach patient breast health awareness and self-examination.
- Teach patient how to inspect genitalia for abnormalities and note changes in vaginal secretions.
- Show patient the packet of contraception pills, and discuss how to recognize start dates and follow the sequential pill dosing. Demonstrate how to remove pill from pill packet if available.
- Teach patient how to place and remove Ortho-Evra patch.
- Teach patient how to place and remove NuvaRing.
- Teach patient how to use a calendar to record placement and removal of NuvaRing or Ortho-Evra patch.
- Advise patient to return for a Depo-Provera injection within the 13-week time frame.

Diet

- Counsel patient to moderate caffeine intake because elimination of caffeine may be decreased as a result of prescribed CHC products.
- Tell patient to take oral contraception products with a snack or after meals to help eliminate nausea.
- Advise patients using Depo-Provera to increase calcium and vitamin D intake and to do 15 to 30 minutes of weight bearing exercises 3 to 4 times per week.
- Discuss foods that increase iron and iron absorption.

Cultural Considerations

- Be aware of different cultures' contraception practices. For example, in some cultures, methods that involve touching the vagina may be difficult for a woman to use.
- Consider religious and spiritual beliefs with regard to contraceptive choices. Be accepting and supportive of beliefs or practices that are not consistent with personal beliefs.

Evaluation

- Encourage patient in planning follow-up evaluations.
- Evaluate patient's adherence with hormonal contraceptive regimen; assess for changes in sexual partners and/or health status that may compromise the method.

OTHER METHODS OF CONTRACEPTION

Spermicides

Spermicides are chemical agents that inactivate sperm before they can travel through the cervix and into the upper genital tract. The most common form of spermicide is nonoxynol-9.

Nonoxynol-9 is infused into a carrying agent such as jellies and creams, foams, suppositories, and films and is also impregnated into the Today Sponge. Some of the carrying agents contain a short-acting spermicide, while others adhere to the vaginal mucosa to provide extended spermicidal action. When combined with barrier methods such as the condom or diaphragm, spermicides increase protection against pregnancy. Nonoxynol-9–based spermicide products are no longer advised to prevent STIs. Spermicide can cause vulvovaginal abrasions and altered vaginal flora, which can increase susceptibility to pathogens.

The Today Sponge is a polyurethane disc containing nonoxynol-9. It is moistened with water, and the excess is squeezed out. It then should be placed snugly against the cervix. It can be inserted up to 24 hours before intercourse but must remain inserted for 6 hours after. This contraceptive product was discontinued in 1995 because of manufacturing problems, but it is again available over-the-counter in stores.

Barrier Methods

Both male and female condoms are available over-the-counter without a prescription. The female condom is a polyurethane (plastic) pouch with flexible rings at each end. It is inserted deep into the vagina like a diaphragm. The ring at the closed end holds the pouch in the vagina. The ring at the open end stays outside the vulva. Male condoms are available in latex, lambskin, and polyurethane. Latex condoms offer very good protection against STIs and HIV. Other barrier methods include the FemCap, cervical cap, and diaphragm, which require a medical visit for proper fitting. Barrier methods are more effective at preventing pregnancy when paired with a spermicide. Appropriate health care teaching for the use of these methods is essential to enhance pregnancy prevention. Patient with latex allergies need to avoid products containing latex.

Intrauterine Contraception

Intrauterine devices (IUDs) and intrauterine systems (IUSs) are safe methods of contraception with high patient satisfaction rates. Although intrauterine contraception methods are used more widely outside the United States, IUDs and IUSs have the highest effectiveness rates of reversible forms of contraception. Both the expected and typical efficacy rate is 99.9%. Patient selection for IUD and IUS use should consider menstrual factors, known or suspected uterine anomalies and fibroids, risk factors for STIs, and history of **pelvic inflammatory disease** (PID). PID is an infection of the upper genital tract, usually the uterine endometrium, the fallopian tubes, or ovaries. After insertion, the device's filamentous strings protrude through the cervix and into the vagina. The strings ensure that the device remains in place and aid in removal when needed. It was previously thought that the strings can act as a "wick," or a mechanism in which microbes can ascend into the endometrial cavity. However, studies show that risk of upper genital tract infections is related to insertion. Thus, PID incidence is minimal after 20 days of insertion.

If a woman contracts an STI while the device is inserted, in most cases the STI can be treated without removing the device. If the patient contracts PID during IUD/IUS insertion, health care providers will remove the IUD/IUS. Age and parity are not significant factors in patient selection for IUD or IUS use. IUDs and IUSs do not increase the risk for ectopic pregnancy. Currently two IUDs are on the market in the United States.

The ParaGard T 380A releases copper, which primarily interferes with the contractions within the uterus impeding sperm migration. A secondary effect is an inflammation of the endometrium, which also obstructs sperm motility and prevents implantation in the rare case that conception should occur. The ParaGard IUD can increase blood loss during menstruation by 35%, and may also increase uterine cramping and blood clots in menstrual flow. The use of NSAIDs helps to decrease both menorrhagia and dysmenorrhea caused by ParaGard. The ParaGard should be inserted up to day 7 of the menstrual cycle, and can remain in place for up to 10 years.

The Mirena levonorgestrel-releasing intrauterine system (LNG-IUS) causes cervical mucus to become thicker so sperm cannot enter the upper reproductive tract or reach the ovum. Changes in uterotubal fluid also impair sperm migration. Alterations in the endometrium prevent implantation in the rare case that conception occurs with the device in place. The LNG-IUS may also suppress ovulation. Unlike the ParaGard IUD, menorrhagia is improved by 90% with the LNG-IUS. This makes the LNG-IUS an effective treatment for heavy menstrual bleeding caused by hormonal dysfunction, uterine fibroids (as long as the fibroid is not located in the uterine cavity), or endometriosis. The LNG-IUS can also be used to decrease perimenopausal bleeding. Dysmenorrhea is also improved. There is a 20% chance of amenorrhea by 1 year of use, which increases to 60% within 5 years. The LNG-IUS is as effective as female sterilization, decreases a woman's risk of PID by 60%, and may also decrease the risk for ectopic pregnancy. The LNG-IUS should be inserted within 7 days of the start of menstruation. During this time the cervical canal is slightly open, making the insertion of the device easier for the provider. The LNG-IUS is effective for 5 years.

Both the ParaGard and the LNG-IUS can be inserted as early as 6 weeks postpartum. There are no contraindications with breastfeeding women and intrauterine contraception. Contraindications to the LNG-IUS are known or suspected pregnancy, uterine anomalies, and risk for acquiring an STI. The LNG-IUS may be effective at preventing endometrial cancer and invasive cervical cancer. The ParaGard should not be placed in women with a small intrauterine cavity (less than 6 cm) or a large intrauterine cavity (greater than 9 cm). Expulsion risk is 5%. There is a slightly higher expulsion rate in women younger than 20 years of age and when the device is inserted immediately postpartum. Perforation of the uterus is a rare complication of insertion.

Women who choose the IUD or IUS for contraception should be taught how to feel for strings of the device, which extend beyond the cervix. The string check is done monthly after the menstrual cycle and ensures that the device has remained in place. Removal of the device is done at the end of the prescribed time frame, when pregnancy is desired, or at the patient's request. The patient should also be advised that she can become pregnant immediately after removal of the device. The device is also removed in the rare event that a pregnancy has occurred with the device intact. The patient should be advised that removal of the device with an intrauterine pregnancy could possibly end in miscarriage. Both types of IUDs can be located on pelvic and transvaginal ultrasound should a question of proper placement or with the occurrence of full or partial expulsion of the device. The patient should be instructed to use a backup method of contraception until the device is found to be in correct placement. The device should be removed by the provider if it found to be incorrectly placed or partial expulsion has occurred. Reinsertion of a new device or an alternative method of contraception should be prescribed if the patient does not want to become pregnant. Fertility returns immediately after removing the device.

Emergency Contraception

Emergency contraception (EC) can prevent pregnancy after unprotected intercourse. It may be prescribed in three ways: (1) using combined hormonal contraceptive pills in a documented effective regimen; (2) using Plan B, which is a progestin-only EC; or (3) inserting a copper-releasing IUD (ParaGard). It is intended to be used one time in the event that a condom breaks, a diaphragm or a cervical cap is displaced, or doses of a hormonal contraception method are missed. EC is indicated in the event of sexual assault. The only documented contraindication to EC is an established pregnancy. Women should be instructed that EC is most effective when taken within 24 hours after unprotected intercourse.

SAFETY: Preventing Medication Errors

Do not confuse …

- **Mifepristone** (RU486) with **misoprostol** (Cytotec) or **methotrexate.** Mifepristone is used for early pregnancy termination by blocking progesterone. Lack of progesterone causes the uterine lining to shed and ends the pregnancy. Misoprostol causes the uterus to contract and is used for early pregnancy termination or for cervical ripening at any gestational age. It can also be used to control postpartum hemorrhage. Methotrexate is a folate antagonist used to manage ectopic pregnancy.

Combined Hormone Contraceptive Pills. Combined oral contraception pills prevent fertilization after an incidence of unprotected vaginal intercourse or failure of contraceptive method. The method includes using estrogen-progestin contraception pills in multiple dosing. This raises both estrogen and progestin levels to delay or prevent ovulation; interfere with tubal transport of the embryo, egg, or sperm; and change the hormones necessary for the preparation of the uterine lining. Using this method decreases the risk for pregnancy by 75% for each act of sexual intercourse. The major side effect is nausea. To prevent this side effect, an OTC antinausea medicine should be taken 1 hour before administration. Antihistamines are the most commonly used OTC medication used for nausea, and some are marketed specifically for this purpose. Antihistamines include diphenhydramine (Benadryl), dimenhydranate (Dramamine), and meclizine (Antivert). Irregular menstrual bleeding is another side effect. If a woman does not begin menstruation within a few days of the expected time, a pregnancy test should be performed. Patients who are unable to take estrogen should not take the usual EC pill dosage.

The original Yuzpe method involved taking two Ovral tablets (norgestrel 0.5 mg and EE 50 mcg) followed by two more tablets 12 hours later. This method was later expanded to include other types of oral contraception pills. Family planning agencies and women's health organizations provide a full list of CHC pills, as well as the dosage and administration regime for these products when used for EC. Treatment should be initiated within 72 hours of intercourse. The sooner a plan is initiated, the more effective it will be at preventing pregnancy.

The first progestin-only emergency contraceptive pill available in the United States is known as Plan B. In 2006, the FDA approved Plan B without a prescription for women age 18 years or older. In 2009, the FDA stated that both men and women can obtain Plan B One-Step without a prescription if they are older than 17 years. Those younger than 17 years need a prescription.

Plan B should be taken within 72 hours after intercourse, but it is still effective 120 hours afterward. If taken within 24 hours of intercourse, EC reduces the risk of pregnancy by 95%. Just 12 hours after the initial 24-hour postcoital period, the effectiveness rate of EC decreases to approximately 60%. With Plan B, two tablets containing 0.75 mg of LNG are dispensed in one package. One tablet is taken in the initial dose, followed by a second tablet 12 hours later. In an alternative dosing schedule, the two tablets can be taken in one PO dose. Plan B One-Step is a newer preparation of emergency contraception that supplies 1 pill containing 1.5 mg of LNG. Instead of taking two 0.75-mg LNG tablets, the patient takes one 1.5-mg LNG tablet. This single dose improves patient compliance and has an increased efficacy rate. Less nausea is associated with Plan B than with estrogen-containing emergency contraceptive methods. The generic form of the original Plan B is available as Next Choice.

Ella is an emergency contraception product that is FDA approved for up to 120 hours after unprotected intercourse. Patients of all ages need a prescription to obtain ella. Ella contains 30 mg of ulipristal acetate, which is a selective progesterone receptor modulator. This drug inhibits ovulation and is also embryotoxic by its progesterone agonist/antagonist activity. Pregnancy must be excluded before taking ella. Ella is pregnancy category X and is considered to be teratogenic and fetotoxic. It is reported that the manufacturers of ella want to maintain its use as an emergency contraceptive option and not promote off-label use as a product for medical abortion.

Hormonal methods of EC are not considered a method of contraception and should not be promoted as such. CHC products, barrier methods, and IUD/IUS devices are more reliable and effective at preventing pregnancy. Women should be instructed that their next menstrual period could be delayed after a dose of EC. If pregnancy is already established or if implantation occurred since the episode of sexual intercourse, the pregnancy is not disrupted and studies indicate that there are no untoward effects on the fetus.

With ella, if pregnancy has been established when the method is administered, the pregnancy can be disrupted and teratogenic fetal effects may occur. Side effects of ella include headaches, nausea, abdominal pain, dysmenorrhea, and dizziness. Breastfeeding mothers should not use ella.

ParaGard. A copper IUD may be inserted within 5 days of unprotected intercourse as a method of postcoital contraception. The device can be removed after the woman's next menstrual period, or it may remain in place as a method of contraception for up to 10 years. The mechanism of action is interruption of sperm migration and penetration of the ovum.

MEDICAL ABORTION

Medical abortion ends a pregnancy that is less than 63 days from the first day of the LMP, or less than 9 weeks' gestation. Medical abortion uses drugs to disrupt an established pregnancy. (Surgical abortion refers to procedures used to remove the products of conception from the uterus.) *Methotrexate* is a medication that stops the pregnancy in the uterus. It may also be used to treat an *early* ectopic pregnancy that is encapsulated and less than 3 cm in size. *Mifepristone*, first marketed as RU486, is an anti-progestin that blocks the hormone progesterone. Without progesterone, the lining of the uterus breaks down, ending support for the embryo. The hormone human chorionic gonadotropin (hCG) is decreased. hCG is produced by the placenta and is the hormone tested to confirm pregnancy; decreasing levels of hCG signify that the pregnancy has been disrupted. *Misoprostol* is then given to cause the uterus to contract and expel the products of conception.

MENOPAUSE

The transitional process experienced by women as they move from the reproductive years into the nonreproductive stage of life is called **menopause.** Menopause is a naturally occurring event and part of the normal life cycle of women. It occurs for most women between their mid-forties and mid-fifties but may start as early as the late thirties. The climacteric has three stages: perimenopause or premenopause, menopause, and postmenopause, during which certain physiologic events occur. As women go through menopause, providers do not treat the cessation of menses, but address the symptoms that may occur with the menopausal passage.

Perimenopause

The perimenopausal period includes the years before the natural cessation of spontaneous menstruation. During this period, menstrual variations become evident. Women may experience short cycles (less than every 25 days), long cycles (more than every 35 days), heavy bleeding, light bleeding, or periods of longer or shorter duration. Women may start to skip periods or abruptly stop menstruating altogether. Oligomenorrhea (very scant periods) or menorrhagia is common. Symptoms experienced during perimenopause are similar to those during menopause, with the exception that perimenopausal women continue to have some type of cyclic bleeding. The most common symptoms are hot flashes (caused by a surge in LH levels) and vaginal dryness (caused by estrogen withdrawal). Other symptoms include insomnia, headaches, irritability, anxiety or other variations in mood, cognitive difficulties, memory lapses, joint aches, and decreased libido. These unpredictable changes may last a short period of time or for several years.

There are a set number of follicles in the ovaries at birth. They are dormant throughout childhood and become active with puberty. Ovarian follicles are high in number during puberty and until age 35 years but the number of follicles steadily decline after age 35 years, and more rapidly after age 40 years. During the menstrual cycle, these follicles provide high levels of estrogen in the form of estradiol. The highest level of estradiol production in women occurs from puberty until the early thirties. Follicular growth, and therefore the secretion of estradiol, is under the influence of FSH and, to a lesser degree, LH, both of which are released by the anterior pituitary gland.

During the perimenopausal period, ovarian follicles become depleted, causing estrogen levels to diminish. The decrease in estrogen is gradual and allows for fluctuating levels of FSH and LH. Subsequently, menstrual cycles become anovulatory and therefore irregular. The onset of menstrual irregularity is one of the early indications of perimenopause. Symptoms are thought to be related to hormone fluctuations, particularly estrogen withdrawal, and increased levels of LH and FSH. Serum FSH testing is used as a marker of follicular activity, and an elevated level of FSH can be an indication of decreased ovarian function.

Menopause

Menopause is the permanent end of spontaneous menstruation caused by cessation of ovarian function. This natural event is documented as having occurred once a woman has stopped menstruating for 1 year. The triggering event is not known. Women who experience menopause before 40 years of age are said to have premature ovarian failure. Menopause can also occur abruptly as a secondary effect of oophorectomy (surgical removal of the ovaries), radiologic procedures in which ovarian function is destroyed, severe infection, ovarian tumors, or as a temporarily induced state for treatment of conditions such as endometriosis. During this transitional period, and with any episodes of menstrual changes/

irregularities caused by perimenopause, women should use contraception until menstruation has ceased for 1 year if they do not want to become pregnant.

Postmenopause

Postmenopause is the stage when the body adapts to a new hormonal environment. The production of estrogen and progesterone from the ovaries decreases during the late premenopausal and early postmenopausal periods. The ovary continues to secrete androgens (testosterone) in varying amounts as a result of the influence of increased LH levels. During postmenopause, androstenedione (the main androgen secreted by the ovaries and adrenal cortex, which is present in reduced amounts postmenopause) is converted into *estrone*, a naturally occurring estrogen formed in extraglandular tissue of the brain, liver, kidney, and adipose tissue. This represents the main source of available estrogen once the ovaries lose the ability to produce estradiol. Table 56-3 presents common physical effects associated with the climacteric.

SAFETY: Preventing Medication Errors

Do not confuse ...

- **Premarin** with **Prempro** or **Premphase.** Premarin is estrogen only for hormone replacement therapy. Both Prempro and Premphase have combined estrogen and progesterone for use by women with an intact uterus to prevent uterine hyperplasia when estrogen is used.

Hormone therapy (HT) significantly improves vasomotor symptoms and vaginal dryness (two frequently encountered symptoms of menopause) and decreases the risk for osteoporosis and osteoporotic fractures. Vasomotor symptoms have the potential to disrupt sleep quality and exacerbate irritability, mood swings, depression, and problems with concentration. Vaginal dryness and atrophic vaginitis, caused by decreases in systemic estrogen, causes dyspareunia, sexual dysfunction, and atrophic vaginitis. Decreased estrogen also has an effect on libido, sexual arousal, and the achievement of orgasm. It also has an untoward effect on urinary health. While no HT product presently has FDA approval for the treatment of osteoporosis, HT decreases the risk of osteopenia, osteoporosis, and fractures resulting from postmenopausal bone mineral density loss. There are systemic HT products that do have FDA approval for prevention of osteoporosis. HT reduces the risk for postmenopausal osteoporotic fractures in the hip, spine and all other possible fracture areas, even in women who do not have osteoporosis. HT can prevent further BMD loss and even improve BMD in women with osteopenia or osteoporosis.

The FDA has issued a boxed warning that states that HT should be used only for the treatment of menopausal symptoms, at the lowest dose possible, for the shortest duration possible, usually less than 5 years (Box 56-3). Most health care providers adhere to this practice when prescribing HT. Health teaching must be done with menopausal women to ensure that they are aware of the risks and benefits of hormone replacement therapy.

TABLE 56-3 COMMON PHYSICAL EFFECTS ASSOCIATED WITH THE CLIMACTERIC

HYPOESTROGENIC STATE	EFFECTS
Irregular menstruation	Variable frequency, duration, flow
LH surge: hot flashes	Hot flashes: transient sensations of intense heat with or without sweating; tachycardia; sleep disruption
Peripheral vascular dilation: hot flashes and night sweats	Hot flashes: visible flushing in upper chest, neck, and head; visible sweating and chills Night sweats: vasomotor symptoms that occur at night
Vulvar and vaginal atrophy	Dryness; decreased lubrication during sexual stimulation; thinning. Decreased acidity and increased irritation response to stressors such as intercourse can cause increased vaginitis (itching, burning, and discharge). Increased incidence of prolapse/cystocele
Decreased bone mass (osteoporosis)	Backache, reduced height, and sudden fracture, particularly in thin, fair, small-boned women and those with a family history, no pregnancies, sedentary lifestyle, inadequate diet, smoking, alcohol use, or use of drugs that increase calcium loss (anticonvulsants, corticosteroids). Most rapid decrease in mass (particularly in hips, spine, and torso) occurs in first 3 to 5 years postmenopause and slows after 65 years of age
Additional Effects Caused by Menopause Combined with Natural Aging	
Urethral disorders	Loss of urethral tone, painful urination, frequency, and stress incontinence
Decreased breast size	Decrease in fatty tissue in the breast and breast density, increase of fibroglandular tissue; breasts may sag and become more pendulous
Decreased skin elasticity	Facial, neck, and hand wrinkling; variations in quantity and distribution of body hair
Lower HDL levels	Increased risk (3 times) for cardiovascular disease as LDL levels increase
Abdominal fat development	Greater degree of central android abdominal fat accumulates because of altered peripheral resistance to insulin and increase in type II diabetes as aging progresses (lower incidence in estrogen users)
Hyperinsulinemia	Signs and symptoms of low blood sugar
Reduced cognitive function	Normal with aging. Loosely associated with estrogen withdrawal. May be related to sleep disorders and increased stress.

HDL, High-density lipoproteins; *LDL,* low-density lipoproteins; *y,* year.

BOX 56-3 FDA BOXED WARNINGS FOR CHC PRODUCTS AND HT PRODUCTS

CHC pill products: "Cigarette smoking increases the risk of serious cardiovascular side effects from oral contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke."

Ortho Evra transdermal patch: "Do not use ORTHO EVRA if you smoke cigarettes and are over 35 years old. Smoking increases your risk of serious cardiovascular side effects (heart and blood vessel problems) from hormonal contraceptives, including death from heart attack, blood clots or stroke. The risk increases with age and the number of cigarettes you smoke."

NuvaRing: "Cigarette smoking increases the risk of serious cardiovascular side effects from combination oral contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use combination hormonal contraceptives, including NuvaRing, should be strongly advised not to smoke."

Hormone replacement therapies with estrogen and estrogen plus progesterone: "Warning: Cardiovascular disorders, breast cancer, endometrial cancer and probable dementia. … Estrogens, with or without progestins, should be prescribed at the lowest effective doses and for the shortest duration consistent with treatment goals and risks for the individual woman."

PHARMACOLOGIC AND COMPLEMENTARY AND ALTERNATIVE THERAPY FOR PERIMENOPAUSAL AND MENOPAUSAL SYMPTOMS

Therapies that are presently being used for the treatment of perimenopausal and menopausal symptoms include complementary and alternative medicine (CAM), bioidentical hormone preparations, and HT.

Complementary and Alternative Medicine

Many women have turned to CAM for the relief of menopausal symptoms. While anecdotally women may find them helpful, randomized controlled trials show that most CAM relief measures and supplemental therapy are not more effective than placebos.

The most commonly used products for hot flashes are natural soy and soy derivatives. Natural soy contains phytoestrogens, called *isoflavones,* which have estrogenic effects. Soy has been made available in many over-the-counter nutritional supplements; however, natural soy products are considered more effective at treating hot flashes. Red clover extract is also used to treat hot flashes, although research studies using red clover extract are inconclusive. The herb *Actaea racemosa,* or black cohosh, is used in the over-the-counter preparations of Remifemin and Estroven. Limited studies show that black cohosh may decrease hot flashes. Caution with this herbal product should be used in patients with breast cancer and liver disease. Vitamin E in oral doses of 400 to 800 IU/day or evening primrose oil in oral doses of 1000 IU/day are used with success by some patients experiencing hot flashes; research does not support the effectiveness of either supplement. St. John's wort may be helpful for menopausal women experiencing mild depression or mood alterations. Ginseng may improve sleep, mood changes, and sense of well-being, while valerian is thought to help with insomnia. Melatonin may also be helpful as a sleep aid. Patients should be aware that these products can have side effects, may interfere with other medications, and are not regulated by the FDA. Women should be encouraged to report the use of herbal supplements, CAM, vitamins and minerals, and over-the-counter medications to their health care provider.

Bioidentical Hormone Therapy

Bioidentical hormone therapy includes estrogen-like compounds that have been derived from plants. These compounds are biochemically similar or identical to those produced by the ovaries. They are custom-made for the patient under the direction of the health care provider.

The most common plants to use for bioidentical hormone products are soy and wild Mexican yam root. Bioidentical hormones are more closely formulated after a woman's naturally occurring hormones, whereas natural hormones are those that originate in animal, mineral, or plant form. Women who ask for "natural" estrogen products may actually be requesting the bioidentical formulation. However, the plant components must undergo a chemical process to change them into the necessary estrogen-like structures that are components of the bioidentical hormone product. Although these compounds may be more estrogen-like than their synthesized counterparts, the term *natural* may be confusing.

The most common commercially available compounds are *estrone*, *estradiol*, *estriol*, *testosterone,* and *micronized progesterone*. The route of administration can be oral, sublingual, implantable, injectable, or in vaginal suppository form. Pellet therapy is a form of bioidentical hormones, usually estradiol and estriol, as well as progesterone and testosterone, implanted subcutaneously, in unnoticeable areas. The pellets are about the size of rice and are specifically compounded for each individual according to age, weight, risk factors, symptomology, and serum blood testing of hormonal and metabolic characteristics. Usually one pellet is placed and has a duration of 4 to 6 months. A new pellet is then inserted.

Theoretically, compared with HT, bioidentical hormones have limited side effects, a reduced risk of exacerbating the growth of breast cancer cells, equal osteoporosis prevention benefits, and a decrease in cardiovascular effects. However, clinical research providing evidence of the benefits and risks of bioidentical hormones is limited. Since the FDA has not approved the use of a combined estrogen-progestin bioidentical product in the United States, combination therapy must be compounded and dispensed by a compounding pharmacy. Also, many bioidentical hormones once compounded are not regulated by the FDA, so purity and quality is a concern. The bioidentical hormones have the same benefits and risks as HT.

Tri-est and *Bi-est* are two commonly prescribed bioidentical estrogen products. Bi-est contains 2 mg estriol and 0.5 mg estradiol in an 80/20 ratio, respectively. Tri-est contains 2 mg estriol, 0.25 mg estrone, and 0.25 mg estradiol in an 80/10/10 ratio, respectively. Many bioidentical estrogens or progestins are presently being used in HT products.

Hormone Therapy

Hormone therapy (HT) (Table 56-4) is used only for the relief of symptoms related to menopause, most commonly hot flashes, vaginal dryness, and associated sleep disorders. HT includes estrogen-progestin therapy (EPT) for use with women who have an intact uterus, and estrogen therapy (ET) for use with women who have had a **hysterectomy** (surgical removal of the uterus). Hysterectomy is performed for a variety of gynecologic problems including cancer, fibroids (benign uterine tumors), uterine prolapse, chronic pelvic pain, and heavy/abnormal uterine bleeding. The nurse should determine if the patient has had a hysterectomy in the past prior to administration of HT. It is the estrogen component in HT that relieves the symptoms of menopause. The progestin is added to protect the uterine endometrium from hyperplasia (an abnormal proliferation or overgrowth of tissue.) When the uterus is exposed to unopposed estrogen (estrogen without concurrent progestins), the endometrium becomes hyperplastic, potentiating the development of endometrial cancer. Estrogen alone can be used with women who have had a hysterectomy. With women who still have their uterus, estrogen, most commonly in the form of conjugated equine estrogens (CEE), is taken together with the synthetic progestin. The progestin, however, has the potential to cause unpredictable uterine bleeding.

SAFETY: Preventing Medication Errors

Do not confuse …

- **CHC products** with **HT products.** Oral, transdermal, and vaginal ring preparations for contraception and HT are dispensed in packages and boxes that are very similar. Once opened, CHC products and HT products may have the same disc-dispensing systems and splintered packaging, and similar-appearing skin patches and vaginal rings. Names can also be confused because of similarity, such as Femcon and Femtrace.

HT is available in oral preparations, transdermal applications, and vaginal preparations. Vaginal preparations are creams, suppositories, or rings. All vaginal preparations contain estrogen only and are very effective in treating vaginal dryness. Three types of estrogens are used in HT products: (1) natural or biological estrogens (including bioidentical estrogens), (2) CEE, and (3) synthetic estrogens.

Natural or biologic estrogens are derived from plants, minerals, or animals and are composed of *estrones* (esterified estrogens, CEEs, and piperazine estrone sulfate) and *estradiols* (micronized estradiol, estradiol valerate, and 17-β estradiol).

CEEs are mixtures of natural estrogens isolated from the urine of pregnant mares. Although CEEs are derived from nonhuman sources, they are naturally occurring estrogens. They are generally classified independently of natural or biological estrogens because they are the longest-used and most commonly prescribed form of estrogen in HT. Premarin, the most frequently used conjugated estrogen product, is presented in Prototype Drug Chart 56-1.

Synthetic estrogens include ethinyl estradiol and mestranol, which are both the same estrogens found in CHC products.

Dosage Forms

The oral route is most commonly used because it is well tolerated by most patients and relatively easy to administer. It requires daily dosing. Some patients experience GI upsets, particularly nausea and vomiting. A patient with GI disorders such as colitis, irritable bowel syndrome, peptic ulcer, or a malabsorption disorder may receive inconsistent doses with oral administration, necessitating the use of another route. Oral estrogens have a particularly beneficial effect on lipids by increasing high-density lipoproteins. Although the oral route does result in complete absorption from the GI tract, there is greater impact on liver proteins. In women with an intact uterus, oral estrogen is combined with a progesterone or progestin, completing the combined therapy. This can be given in a separate estrogen tablet combined with a separate progestin tablet (two oral pills taken daily) or in a combined estrogen-progestin tablet (one oral pill taken daily). Oral estrogens are typically used continuously. Common ET products include Premarin (CEE), Estrace (17 β-estradiol), Cenestin (synthetic conjugated estrogen), and Menest (esterified estrogen).

The transdermal skin patch is a convenient method to deliver ET because it does not require daily dosing. The patch is applied to intact skin in the prescribed dosage. Generally the lower abdomen is used, but other sites may be used. As with the Ortho-Evra transdermal patch used for contraception, the HT patch should not be placed on or near the breasts. The transdermal patch allows for absorption of the estrogen directly into the bloodstream through a membrane that limits the absorption rate. All types of transdermal patches, both estrogen only and estrogen-progestin combination patches, contain 17-β estradiol, which is a plant derivative. The advantage is the same as the first-pass avoidance in CHC products using the transdermal route. The GI tract and liver are bypassed initially, which results in less nausea and vomiting and less impact on the hepatic system. Some women prefer to take an estrogen derived from a plant source. Transdermal patches are changed twice a week or weekly, depending on the product. They are used continuously. Examples of transdermal estrogen systems are Climera, Estraderm, Vivelle, and Vivelle-Dot. A progestin should be taken concurrently with the estrogen patch in women with an intact uterus.

TABLE 56-4 ESTROGENS AND PROGESTINS USED IN HORMONE THERAPY

PRODUCT NAME	TYPE OF ESTROGEN OR ESTROGEN/PROGESTIN	ROUTE OF DELIVERY	DOSE
Conjugated Estrogens			
Premarin	See Prototype Drug Chart 56-1.		
Estrogen Products (ET) Oral Administration			
Cenestin	synthetic conjugated estrogen	Tablet	0.3 mg, 0.45 mg, 0.625 mg, 0.9 mg, 1.25 mg daily PO
Enjuvia	synthetic conjugated estrogen	Tablet	0.3 mg, 0.45 mg, 0.625 mg, 0.9 mg, 1.25 mg daily PO
Estrace	micronized estradiol	Tablet	0.5 mg, 1.0 mg, 2.0 mg daily PO
Femtrace	Estradiol	Tablet	0.45 mg, 0.9 mg, 1.8 mg daily PO
Menest	esterified estrogens	Tablet	0.3 mg, 0.625 mg, 1.25 mg, 2.5 mg daily PO
Ogen	Estropipate	Tablet	0.625 mg, 1.25 mg, 2.5 mg daily PO
Ortho-Est	Estropipate	Tablet	0.625 mg, 1.25 mg daily PO
Premarin	CEE	Tablet	0.3 mg, 0.45 mg, 0.625 mg, 0.9 mg, 1.25 mg, 2.5 mg daily PO
Estrogen Products (ET) Transdermal Administration			
Alora	Estradiol	Matrix patch	0.025, 0.05, 0.075, 0.1 mg/d applied to skin 2 times/wk
Climera	Estradiol	Matrix patch	0.025, 0.0375, 0.05, 0.06, 0.075, 0.1 mg/d applied to skin q wk
Divigel	Estradiol	Topical gel	0.25, 0.5, 1.0 mg/packet applied to the skin once daily
Elestrin	Estradiol	Topical gel	0.87 g/pump applied to the skin once daily
Estraderm	Estradiol	Reservoir patch	0.05, 0.1 mg/d applied to skin 2 times/wk
Estrasorb	Estradiol	Topical emulsion	1.74 g/pouch; 2 pouches applied to skin daily
Estrogel	Estradiol	Topical gel	1.25 g/pump; 1 pump applied to skin daily
Evamist	estradiol	Topical spray	1.53 mg/spray; 1 spray/d, may increase to 2-3 times/d PRN
Menostar	Estradiol	Matrix patch	0.014 mg/d applied to skin q wk
Minivelle	Estradiol	Patch	0.0375, 0.05, 0.075, 0.1 mg/d applied to the skin 2 times/wk
Vivelle	Estradiol	Matrix pouch	0.05, 0.1 mg applied to skin 2 times/wk
Vivelle-Dot	Estradiol	Matrix pouch	0.025, 0.0375, 0.05, 0.075, 0.1 mg/d applied to skin 2 times/wk
Vaginal Estrogen Products			
Estrace	Estradiol	Vaginal cream	0.01% (0.1mg/g) daily for 2 wk, then 1- 3 times/wk intravaginal
Estring	Estradiol	Vaginal ring	7.5 mcg/24 h; 1 ring intravaginal q90d
Femring	Estradiol	Vaginal ring	0.05 mg/d, 0.1 mg/d; 1 ring intravaginal q3mo
Premarin	CEE	Vaginal cream	0.625 mg/d intravaginal daily
Vagifem	Estradiol	Vaginal tablet	25 mcg; 1 tab intravaginal daily for 2 wk, then 2 times/wk
Estrogen and Progestin/Progesterone Combination Products (EPT) Oral Administration			
Activella	estradiol and norethindrone acetate	Tablet	0.5 mg and 0.1 mg; 1 mg and 0.5 mg PO daily
Angeliq	estradiol and drospirenone	Tablet	0.5 mg and 0.25 mg; 1 mg and 0.5 mg PO daily
FemHRT	EE and norethindrone acetate	Tablet	2.5 mcg and 0.5 mg; 5 mcg and 1 mg PO daily
Prefest	EE, then EE and norgestimate	Tablet	1.0 mg, then 1.0 mg and 0.09 mg PO daily
Premphase	CEE (14 tabs), then CEE and MPA (14 tabs)	Tablet	0.625 mg (first 14 days), then 0.625 mg and 5 mg PO daily sequentially
Prempro	CEE and MPA (28 tabs)	Tablet	0.3 mg and 1.5 mg; 0.45 mg and 1.5 mg; 0.625 mg and 2.5 mg PO daily
Estrogen and Progestin/Progesterone (EPT) Transdermal Administration			
Climara Pro	estradiol and LNG	Matrix patch	0.045 mg and 0.015 mg/d applied to skin q wk
Combipatch	estradiol and norethindrone acetate	Matrix patch	0.05 mg and 0.14 mg; 0.5 mg and 0.25 mg/d applied to skin 2 times/wk

Continued

TABLE 56-4 ESTROGENS AND PROGESTINS USED IN HORMONE THERAPY—cont'd

PRODUCT NAME	TYPE OF ESTROGEN OR ESTROGEN/PROGESTIN	ROUTE OF DELIVERY	DOSE
Progestins and Progesterone Products			
Used for HT (to prevent endometrial hyperplasia in women with an intact uterus who are on estrogen), to promote withdrawal bleeding in women with amenorrhea, and monthly or bimonthly to cycle withdrawal bleeding as endometrial hyperplasia prophylaxis in women with amenorrhea			
Aygestin	norethindrone acetate	Tablet	HT: 5 mg PO daily (not used for endometrial hyperplasia prevention or amenorrhea) Endometriosis: 5 mg PO daily for 2 wk; increase by 2.5 mg daily for 2 wk. *Max:* 15/mg daily for 6-9 mo
Prometrium	micronized progesterone	Capsule	HT: 100 mg; 200 mg PO daily h.s. Endometrial hyperplasia prevention: 200 mg PO daily h.s. for 12 consecutive days q mo Amenorrhea: 400 mg PO daily for 10 days h.s.
Provera	MPA	Tablet	HT: 2.5 mg; 5 mg; 10 mg PO daily Endometrial hyperplasia prevention: 5-10 mg PO daily for 12-14 d q mo starting on day 1 or day 16 Amenorrhea: 5-10 mg for 5-10 d

CEE, Conjugated equine estrogen; *d,* day; *g,* gram; *h.s.,* at bedtime; *LNG,* levonorgestrel; *max,* maximum; *mcg,* microgram; *mg,* milligram; *mo,* month; *MPA,* medroxyprogesterone acetate; *PO,* by mouth; *PRN,* as needed; *q,* every; *transvag,* transvaginally; *wk,* week
ET, pregnancy category X; *EPT,* pregnancy category X; *Aygestin,* pregnancy category X; *Provera and Prometrium,* exposure in first trimester may cause genital abnormalities in the fetus. HT in nursing mothers is not recommended.

PROTOTYPE DRUG CHART 56-1

Conjugated Estrogens

Drug Class
Estrogen replacement
Trade Name: Premarin
Pregnancy Category: X

Dosage
A: PO: 0.3, 0.45, 0.625, 0.9, and 1.25 mg daily or cyclically (with or without progestins)

Contraindications
Undiagnosed vaginal bleeding, pregnancy, lactation, severe liver disease, venous thrombosis and personal history of breast cancer
Caution: Cardiovascular disease, severe renal disease, diabetes mellitus

Drug-Lab-Food Interactions
Drug: Increase effects with corticosteroids; decrease effects of anticoagulants, oral hypoglycemics; decrease effects with rifampin, anticonvulsants, barbiturates; toxicity with tricyclic antidepressants

Pharmacokinetics
Absorption: PO: Well absorbed
Distribution: PB: Widely distributed; crosses placenta and enters breast milk
Metabolism: t½: UK
Excretion: In urine and bile

Pharmacodynamics
PO/IV: Onset: Rapid, Peak: UK, Duration: UK
IM: Onset: Delayed

Therapeutic Effects/Uses
Moderate to severe vasomotor symptoms of menopause and vaginal dryness/atrophy
Mode of Action: Develops and maintains female genital system, breast, and secondary sex characteristics; increased synthesis of protein

Side Effects
Nausea, vomiting, fluid retention, breast tenderness, leg cramps, breakthrough bleeding, chloasma

Adverse Reactions
Jaundice, thromboembolic disorders, depression, hypercalcemia, gallbladder disease
Life-threatening: Thromboembolism, cerebrovascular accident, pulmonary embolism, myocardial infarction, endometrial cancer

A, Adult; *d,* day; *IM,* intramuscular; *IV,* intravenous; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown.

HT is also available in topical gels, emulsions, and sprays. EstroGel, Divigel and Elestrinare synthetic plant-based transdermal estradiol gels applied once daily for the treatment of moderate to severe vasomotor symptoms. A thin film is applied to one arm from the shoulder to wrist. The gel dries in 2 to 5 minutes. EstroGel and Elestrin are packaged in a non-aerosol, metered-dose pump, while Divigel comes in single-dose packets. The dosage regime is designed to deliver a specific amount of estradiol with each application.

Estrasorb is the first prescription topical emulsion for estrogen therapy. Estrasorb delivers consistent levels of estradiol into the bloodstream in a lotion-like emulsion, applied daily to the skin on the legs for the relief of moderate to severe vasomotor symptoms. Estrasorb should be applied in a comfortable sitting position to clean, dry skin on both legs each morning.

Evamist is delivered in one spray daily to the skin of the inside of the forearm between the elbow and wrist.

With the topical ET products listed above, a progestin should be taken concurrently in women who have an intact uterus.

Medroxyprogesterone acetate or MPA (Provera) is an oral progestin most often administered in combination with estrogen. Other available products are norethindrone acetate (Aygestin) and micronized progesterone (Prometrium).

Combination products contain both estrogen and a progestin, which offers the added convenience of not having to take two pills daily. Combination products have the same adverse effects as estrogen-only and progestin-only HT. Samples of combination oral HT products include Activella (estradiol and norethindrone acetate), FemHRT (EE and norethindrone acetate), and Prempro (CEE and MPA). The newest form HT is Angeliq (0.5 mg drospirenone and 1 mg estradiol). It is the only HT with the unique progestin drospirenone, and it carries the same precautions as those drugs.

Two combination estrogen-progestin transdermal products are available: ClimaraPro is a thin translucent patch containing estradiol and levonorgestrel, and Combipatch contains estradiol and norethindrone acetate. ClimaraPro is the first once-a-week combined HT approved to treat menopausal symptoms such as hot flashes. Combipatch is placed twice a week. The transdermal patch allows for continuous delivery of hormones at much lower doses than in oral HT. This route avoids the first-pass of the liver and may be better tolerated by women.

Vaginal cream preparations are used in the treatment of vaginal atrophy, which causes painful intercourse and urinary difficulties. Estrace contains estradiol cream, while Premarin contains CEE cream. Both preparations are rapidly absorbed into the bloodstream via the mucous membranes that line the vagina. Vaginal creams may be used in conjunction with another method, such as tablets or the transdermal patch. However, vaginal creams do not need a progestin counter because they do not affect the uterine endometrium to the extent that oral and transdermal products will. Vaginal creams are usually delivered in the dose of 0.5 to 2 g intravaginally daily for 2 weeks; then the dosing is decreased to twice weekly.

Estring is an elastomer ring containing 2 mg of 17-β estradiol, a bioidentical estrogen. The Estring ring is inserted into the upper portion of the vagina, where it releases 50% to 60% of estradiol, providing a consistent low dose of estrogen for 3 months. Estring is used to treat local symptoms of urogenital atrophy, which affects 20% to 40% of postmenopausal women.

FemRing is the first vaginal ERT used to treat moderate to severe hot flashes, night sweats, and vaginal dryness in menopause. FemRing contains estradiol acetate, an estrogen, in a soft, flexible silicone ring. It is inserted into the upper vagina for 3 months. It may be left in place during intercourse and during treatment for vaginal infections. The FemRing attains higher levels of serum estrogen than the Estring, so a progestin counterpart must be prescribed for women with an intact uterus.

Vagifem is a vaginal estrogen tablet that contains estradiol. One 25-mcg tablet is inserted intravaginally once daily for 2 weeks, and then the dose is decreased to one 25-mcg tablet twice weekly. Vagifem tablets have lower circulating estrogen levels than vaginal creams.

Contraindications

Contraindications to HT include pregnancy, history of endometrial cancer (when treatment for early endometrial cancer has been completed, it is no longer a contraindication to HT), personal history of breast cancer, history of thromboembolic disorders, acute liver disease or chronic impaired liver function, active gallbladder or pancreatic disease, coronary artery disease (CAD), undiagnosed vaginal bleeding, and endometriosis. Lifestyle factors such as smoking, known to enhance the risk of thromboembolism, should be considered in the treatment decision. The patient with a history of fibroid tumors is not started on HT for a full year after the last menstruation, because estrogen would likely result in tumor growth. The hypoestrogenic state associated with natural menopause usually causes existing fibroids to shrink. The presence of fibrocystic breast disease or diabetes may require extra caution.

Pharmacokinetics Natural estrogens are completely and rapidly absorbed from the GI tract and rapidly metabolized by the liver, necessitating daily doses when oral products that are nonesterified (a process that delays metabolism and lengthens action) are used. About 80% of estradiol is bound to sex-hormone–binding globulin, with 2% unbound and the rest bound to albumin. Estradiol is converted to estrone in the enterohepatic circulation and is conjugated and excreted via the urine. Conjugated estrogens have a longer half-life than natural estradiols. However, it is difficult to measure blood levels of estrogen with conjugated estrogens. Progestin (Provera) is rapidly absorbed and metabolized primarily in the liver with excretion via the kidney; distribution of the agent is not well described. With vaginal creams, there is a systemic absorption of estrogen. The levels are much lower than those found in oral and transdermal preparations. There is a first-pass bypass of the hepatic system with both vaginal and transdermal preparations. On the first day of vaginal ring use, estrogen levels are elevated and then fall quickly to preinsertion levels.

Other Drugs for Menopausal Symptoms

Women who are not candidates for HT (more specifically, women with contraindications and breast cancer survivors) can be prescribed other medications.

SSRIs. Selective serotonin reuptake inhibitors (SSRIs) reduce the number and severity of vasomotor symptoms in women. SSRIs also have the added benefit of reducing depression, which may relieve irritability and mood changes associated with menopause.

Clonidine. Clonidine (Catapres, Kapvay), a medication used for hypertension, also reduces the number and severity of vasomotor symptoms in women. It is currently being used for this purpose for women in whom HT is contraindicated. Blood pressure must be monitored at regular intervals and the medication discontinued if hypotension occurs.

Gabapentin. Gabapentin (Neurontin) is an antiseizure medication that reduces the number and severity of vasomotor symptoms in menopausal women. Gabapentin should be limited to those women who cannot take HT medications and have vasomotor symptoms that are affecting quality of life. Gabapentin can cause drowsiness and should not be used concurrently with other medications with similar precautions, or if the patient's activities of daily living include those that would be affected or even dangerous if sleepiness, dizziness, or syncope occur.

Osteoporosis

Osteoporosis is a progressive, debilitating skeletal disease that affects older men and women. Women older than 50 years are at greatest risk since the loss of estrogen during menopause is directly related to loss in bone mineral density. Bone mass is at its highest density at age 30 years and then steadily declines. Osteoporosis occurs through an imbalance of osteoblasts (bone-building cells) and osteoclasts (cells that break down bone), which causes bone reabsorption to be excelled. This imbalance causes both deterioration of the microstructure within the bone and a decrease bone density. The loss of bone structure and "porous bone" fragility lead to the risk for fractures. Osteoporosis has significant morbidity and mortality in the United States. The most serious fracture site is the hip. Hip fracture is the second most common reason for older women being placed in nursing homes, exceeded only by Alzheimer's disease. Women who experience hip or vertebral fracture may have long-term, progressive, and debilitating health problems that can eventually lead to death. More than half of U.S. women older than 50 years have some degree of **osteopenia** (low BMD) or osteoporosis (severe decline in BMD).

Diagnosis of osteopenia and osteoporosis is made by axial skeletal measurements of bone density in the lumbar spine and hip through dual energy X-ray absorptiometry or DXA scan. The World Health Organization (WHO) defines osteopenia and osteoporosis by transferring the results of the DXA scan into a T-score. Normal BMD is a T-score of –1 or greater. Osteopenia is defined by a T-score of –1 to –2.5 and, osteoporosis is defined by a T-score of –2.5 or less.

HT is no longer recommended for the *treatment* of osteoporosis but should be considered as a *preventive* measure in postmenopausal women who are at risk. Women who have used HT for 5 years or more have been shown to have a reduction in hip and vertebral fractures by 35%. Other medications can manage osteoporosis and prevent fractures without the concerns that are raised by HT. These include bisphosphonates, which can reduce the breakdown of bone microstructure, and selective estrogen receptor modulators (SERMs). SERMs are a new class of synthetic estrogens. SERMs act like estrogens in certain parts of the body (such as the bones) while leaving other parts unaffected. Evista is an example of a SERM used to treat osteoporosis. Contraindications to SERM therapy include past history or risk for VTE and pregnancy. Caution is used in women with heart disease, risk of MI or stroke, and hepatic or renal insufficiency.

The side effects of oral bisphosphonates include nausea, abdominal/stomach pain, difficulty swallowing, esophageal inflammation, reflux, and ulcers. Injectable bisphosphonates do not have the gastrointestinal side effects, and it can be easier for the patient to schedule a quarterly or yearly injection than to remember to take a daily or weekly pill. A rare complication of bisphosphonates is full or partial spontaneous femur fractures. Oral bisphosphonates should not be taken with aspirin, nonsteroidal antiinflammatory drugs (NSIADs), or antacids. Contraindications to bisphosphonates include esophageal abnormalities or delayed emptying of the esophagus, inability to sit or stand for 30 minutes after oral ingestion, and hypocalcemia.

Nursing Interventions

Prevention of osteoporosis includes sufficient intake of calcium and vitamin D throughout the lifespan by either dietary intake or supplementation. The recommended daily requirement of calcium for women age 25 to 50 years is 1000 to 1200 mg/day, while women older than 50 years need 1200 to 1500 mg/day. Calcium should be taken in divided doses and with adequate vitamin D to enhance absorption. The recommended daily allowance of vitamin D is 400 to 800 IU/day for women age 25 to 50 years and 1000 to 2000 IU/day for women older than 50 years. All calcium preparations, with the exception of calcium citrate, should be taken with food. Smoking cessation should be encouraged because smoking interferes with vitamin D absorption. Alcohol consumption should limited to one alcohol drink per day, since alcohol reduces gastrointestinal absorption of calcium. Weight-bearing exercise strengthens the bones, increases muscle strength, and enhances balance. Weight-bearing exercises include walking, jogging, low-impact aerobics, weight training, and yoga. Caution should be used in patients who are prescribed medications that cause hypotension or dizziness. The patient should be assessed for fall risk, and the prevention of falls should be part of the nurse's health care teaching.

Medications

Estrogen is no longer recommended for the treatment of osteoporosis but may be of benefit in the prevention of osteoporosis. The benefit-risk–alternative ratio should be considered in patients who are candidates for HT. Most preparations of HT (oral and transdermal EPT or ET) can be used for prevention of osteoporosis. Vaginal preparations are not effective.

Menostar (estradiol transdermal system) is 14 mcg of 17-β estradiol in a transdermal, once-a-week patch used for prevention of postmenopausal osteoporosis. This estrogen patch is the lowest transdermal dose available. It is available for women who are unable to tolerate alternative therapies. For women with an intact uterus, a progestin is only recommended every 6 to 12 months.

Alendronate (Fosamax) is a bisphosphonate used to treat osteopenia and osteoporosis. It is available in a daily or weekly dose. For prevention, the oral daily dose is 5 mg/day and the oral weekly dose is 35 mg/week. For treatment, the oral daily dose is 10 mg/day, and the oral weekly dose is 75 mg/week. Fosamax must be taken with 8 ounces of water 30 minutes before ingesting any food, liquids, or medication, and the patient must remain upright for 30 minutes. Once-a-week dosing has made this a first-line therapy. Common side effects include abdominal pain and acid reflux. Fosamax Plus D (vitamin D is added) is also available for enhanced absorption of calcium.

Ibandronate sodium (Boniva) is a once-a-month bisphosphonate indicated for the treatment and prevention of osteoporosis in postmenopausal women. It comes in oral dosing and intravenous dosing. The oral dose has the same directions for use and side effects as the other bisphosphonates. Boniva can be administered in 2.5-mg once-daily tablets, 150-mg once-monthly tablets, or 3-mg every 3 months administered IV over 15 to 30 seconds.

Risedronate (Actonel) is also available in a daily or weekly dose. It has similar directions for use and side effects as the bisphosphonates. The dosing schedule is a 5-mg tablet once daily or 35-mg tablet once weekly. Actonel is also available in Actonel with Calcium. The risedronate tablet is taken once weekly followed by a 500-mg tablet taken once daily on days 2 through 7. Atelvia is the only drug used for osteoporosis that has a delayed-release formulation. Atelvia contains 35 mg of risedronate and is taken once a week, immediately following breakfast and with at least 4 ounces of water.

Reclast is a bisphosphonate that is administered IV in a 5-mg dose yearly. The IV dose should be administered over 15 minutes. Kidney failure is a rare but serious condition that may be associated with the use of Reclast in patients with underlying renal disease or renal impairment. Reclast can be given in a 5-mg dose every 2 years for prevention of osteoporosis.

Nurses should teach patients to advise their health care provider of any increased thigh or groin pain, which can be symptoms of rare, atypical femur fractures.

Studies suggest that some patients may be able to discontinue the use of these medications after 3 to 5 years and still benefit from using bisphosphonates. Health care providers should reassess patients on an individual basis every 5 years to determine whether continued therapy is beneficial. It has been determined is that bisphosphonates do work to improve osteoporosis; however the time frame for safe use of these medications needs to be investigated. There is ongoing research to determine whether the use of bisphosphonates increases the risk for esophageal cancer, which is extremely rare in women.

Raloxifene (Evista) is a SERM that increases bone mineral density, decreases bone turnover, and reduces vertebral fractures. A secondary analysis of osteoporotic women treated with raloxifene showed a decrease in the risk for breast cancer. Side effects include hot flashes and increased risk for DVT. Evista is taken orally once a day in 60-mg tablet.

Teriparatide (Fortéo) is a parathyroid hormone used for treatment of postmenopausal osteoporosis. It is administered 20 mcg subQ on a daily basis. It can be used by both men and women who have had a fracture related to osteoporosis or who have multiple risk factors for fracture and cannot use other osteoporosis treatments. The patient can be taught self-administration.

Salmon calcitonin (e.g., Fortical, Miacalcin) is composed of calcitonin, a naturally occurring hormone that regulates calcium in the body and promotes bone metabolism. It is delivered via intranasal spray in a 200-IU dose administered daily.

Denosumab (Prolia) is an osteoclast inhibitor used in women who are at a high risk for osteoporotic fracture, have had a fracture, or have not had improvement in T-score after using the bisphosphonates for osteoporosis. A 60-mg dose is given subcutaneously every 6 months.

Nursing Process
Patient-Centered Collaborative Care

Management of Symptomatic Menopausal Women

Assessment

- Obtain a record of patient's drug, supplement, and CAM use.
- Obtain baseline vital signs including TPR and BP, weight, and height. Report abnormal findings.
- Obtain family history assessing for risk factors regarding osteoporosis, osteoporotic fractures; cardiovascular risks including CAD, ischemic and hemorrhagic stroke, VTE, cognitive disorders, and cancers that affect women.
- Obtain a history of allergies to medications, foods, and supplements.
- Obtain a medical-surgical history, asking about present or past hypertension; falls and fractures; cardiovascular disease; cerebral vascular disorders; hepatic, renal, and urinary tract disorders and infections; gastrointestinal problems; neurologic disorders; and past systemic infections. Assess for past and present history of cancer. Ask about previous surgeries, in particular gynecologic or pelvic surgery. Assess for smoking, alcohol, and illicit drug use. Assess risk for falls, fractures, self-care concerns, and ability to take medications.
- Obtain a complete menstrual history including age at menarche and age at menopause. If the patient is perimenopausal, assess menstrual pattern; cycle length, duration, and amount of bleeding; and first day of LMP

and method used for contraception. If patient is in menopause, assess past and present menopausal symptoms along with effect on quality of life. Assess for any incidence of postmenopausal bleeding.
- Obtain a full gynecologic history, including last Pap testing, results, history of abnormal Pap testing and colposcopy, and gynecologic problems, disorders, and surgeries.
- Obtain a complete sexual history, including sexual expression practices, sexual risk practices, menopausal symptoms and effects on sexual expression, and past or present sexual abuse and/or assault.
- Assess patient's perception of menopause and knowledge of nonpharmacologic and pharmacologic hormone therapies.

Nursing Diagnoses

- Deficient knowledge of perimenopause and menopause
- Decisional conflicts related to starting/continuing HR
- Deficient knowledge related to HR method(s) and appropriate use of method
- Fear related to HR potential side effects
- Risk for infections related to unprotected intercourse
- Risk for alterations in bone mineral density related to systemic decreases in estrogen
- Risk for falls and/or osteoporotic fracture
- Disturbed body image related to changes in body related to menopause
- Ineffective sleep patterns and sleep-wake health related to perimenopause (or menopause)
- Health-seeking behaviors related to seeking relief of symptoms

Planning

- Patients with contraindications to HT will be risked out.
- Patient will verbalize menopausal symptoms and understand nonpharmacologic and pharmacologic measures that may aid in alleviating symptoms.
- If patient elects HT, she will choose the route of administration that is best suited for her lifestyle and will increase safety and effective use of the product.
- Patient will understand difference between EPT and ET.
- Patient will report side effects that occur.
- Patient will self-administer oral, transdermal, topical, or vaginal medications as prescribed.
- Patient will place patch as directed and will report adverse side effects that occur.
- Patient will be comfortable with vaginal placement of medications.
- Patient will report abnormal uterine bleeding and other side effects associated with HT.
- Explain dosing schedule, risks, benefits, and alternatives to patient.
- Patient will schedule follow-up appointment as needed.

Nursing Interventions

- Teach patient about nature of climacteric, its potential effects, and benefits, risks and alternatives of both nonpharmacologic as well as pharmacologic treatment modalities.
- Determine patient's misconceptions about HT, and provide factual, research-based information.
- Use BRAIDED method in assisting patient in choosing a HT method.
- Use health teaching to encourage effective use of HT.
- Place current educational materials in health and community sites.

Patient Teaching

General

- Review risks, benefits, and alternatives for use of HT.
- Review contraindications to HT.
- Advise patient to have a breast examination, pelvic examination, and Pap test before starting HT.
- Tell patient that warm weather and stress exacerbate hot flashes.
- Advise patient to use a fan, drink cool liquids, and decrease intake of caffeine and spicy foods.
- Advise individuals with diabetes, hypertension, or rheumatic heart disease to use vitamin E in low doses with health care provider's approval.
- Encourage patient on HT to have medical follow-up every 6 to 12 months, including blood pressure check, clinical breast examination, and pelvic examination.
- Stress need to use a method of contraception until 1 year after cessation of spontaneous menstruation.
- Suggest to patient that she use a water-soluble vaginal lubricant to reduce painful intercourse (dyspareunia) and prevent trauma.
- Advise patient to decrease use of antihistamines and decongestants if she experiences vaginal dryness.
- Advise patient to wear cotton underwear and pantyhose with a cotton liner and to avoid douches and feminine hygiene products.
- Suggest that patient take HT oral medications after meals to avoid nausea and vomiting.
- Advise patient that she may experience some vaginal bleeding that should stop 3 to 6 months after starting HT.
- Suggest that patient carry sanitary pads or tampons for breakthrough bleeding or irregular menstruation.
- Advise patient to report any heavy bleeding or irregular bleeding patterns and to have hematocrit and hemoglobin evaluated.
- Advise patient that after HT is discontinued, there may be a recurrence of menopausal signs and symptoms such as hot flashes.
- Tell patient that if she wants to stop HT, she should do so with guidance of her health care provider.

Self-Administration

- Teach patient about breast health and to perform regular breast self-examination.
- Teach patient to perform regular genital inspections.
- Advise patient of when she is due for Pap screening.
- If patient uses vaginal cream, review application procedure and suggest that she wear mini-pads.
- If patient uses the transdermal patch, teach her to open the package and apply it immediately and to hold it in place for about 10 seconds; check edges to ensure adequate contact; use the abdomen (except the waistline) for patch; rotate sites with at least 1 week before reuse of a site; do not use breast as a site; do not put patch on an irritated or oily area; do not reapply patch if it loosens, or apply a new one; and follow same cycle schedule.
- Advise patient about appropriate use of gels, sprays, and mists.

Balanced Diet and Exercise

- Teach patient about osteoporosis prevention: (1) weight-bearing exercise; (2) well-balanced diet (high in fiber, vegetables, fruits, whole grains, and plant proteins; low in animal proteins and sugar); (3) supplement of 1000 mg/d calcium (if premenopausal) or 1200 to 1500 mg/d (if menopausal) and vitamin D 1000 to 2000 IU/d; (4) smoking cessation and reduced alcohol consumption.

Evaluation

- Evaluate effectiveness of nonpharmacologic or pharmacologic measures for premenopausal symptoms.
- Determine whether side effects occur. Plan with patient alternative measures to control menopausal symptoms.
- Plan follow-up appointments and health care screenings.

CRITICAL THINKING CASE STUDY

TA (gravida 3, para 1) is ready to leave the hospital after delivery of a healthy baby. TA had developed gestational hypertension during her pregnancy, but she had no prior history of hypertension. She plans to breastfeed for 3 months. She desires contraception and asks about hormonal contraceptive methods.

1. TA asks whether she can take combination birth control pills while breastfeeding. What are the nursing diagnoses for TA based on her communication? Are other CHC methods available for TA besides the pill? What CHC start method is best for TA?
2. The nurse tells TA that she may breastfeed and can start using combination pills in about 6 weeks when her milk flow is established. Is this information correct or incorrect? Why? What further information will TA need?
3. What other methods of oral contraception are available for TA that would not affect quantity and quality of breast milk? What nursing health teaching should be stressed with the initiation of these products?
4. TA asks if there are any advantages to using oral contraceptives rather than a Mirena LNG-US. What are four advantages and four disadvantages the nurse could include in the discussion? What health teaching would the nurse provide for TA to ensure that she will use COC pills correctly?

NCLEX STUDY QUESTIONS

1. The nurse is preparing a teaching plan for combined oral contraceptive use. Which information should the nurse include in the teaching plan? (Select all that apply.)
   a. The patient should report abdominal pain, chest pain, headaches, blurred vision and visual disturbances, and severe leg pain.
   b. COCs are safe for smokers older than 35 years who smoke less than 20 cigarettes per day.
   c. COC use will not protect from STIs.
   d. The pills can be missed, but not for more than 12 hours.
   e. Vaginal spotting after starting CHC pills is a sign that the method is not effective in preventing pregnancy.
2. A 54-year-old menopausal patient comes into the gynecology office and is interested in hormone therapy. Which are indications for prescribing hormone therapy? (Select all that apply.)
   a. Relief of hot flashes
   b. Prevention of breast cancer
   c. Prevention of cardiovascular disease
   d. Prevention of osteoporosis in a high-risk patient
   e. Relief of vaginal dryness

3. A 24-year-old patient tells the nurse that she would like to use the minipill for contraception. Nursing evaluation of this patient as a candidate for the progestin-only pill includes what?
   - **a.** Obtaining an obstetrical history to make sure that the patient has given birth in the past.
   - **b.** Obtaining a gynecologic history to assure that the patient has regular periods.
   - **c.** Assessing patient reliability in taking an oral pill daily.
   - **d.** Interviewing the patient about past smoking habits.
4. A 39-year-old patient who smokes one pack per day asks about a contraception method that is best for her. She is normotensive and has used CHC pills in the past. She is in a monogamous relationship and has had two children with no complications during pregnancy. She is not planning any more pregnancies. The nurse determines that which method would be best for this patient?
   - **a.** Combined hormone contraception pills
   - **b.** The Mirena LNG/IUS
   - **c.** Progestin-only pills
   - **d.** Plan B
5. An 18-year-old woman calls the clinic office and tells the triage nurse that she had sex last night and the condom broke. She is concerned about unintended pregnancy. Which statement made by the triage nurse is the best advice for this patient?
   - **a.** "Plan B One-Step is available over the counter."
   - **b.** "You should make an appointment with the provider for a prescription of ulipristal acetate (Ella)."
   - **c.** "You have time to wait a few days to make a decision."
   - **d.** "The provider can insert an intrauterine device. I will make an appointment for you."
6. The nurse is instructing a patient on the use of medroxyprogesterone acetate (Depo-Provera). Which statements are correct? (Select all that apply.)
   - **a.** "Patients using Depo-Provera usually do not have any changes in their periods."
   - **b.** "You should increase your intake of calcium."
   - **c.** "You can expect some irregular bleeding at first."
   - **d.** "You can use Depo-Provera if you are breastfeeding."
   - **e.** "Depo-Provera also helps with postpartum depression."
7. The nurse is counseling a 62-year-old patient with a T-score on her Dexa Scan of –2.0. What is the best advice for this patient?
   - **a.** The patient's diet should be supplemented with daily calcium, 1200 to 1500 mg orally in the morning.
   - **b.** The patient should increase weight-bearing exercises like swimming and cycling.
   - **c.** The patient most likely will be prescribed a drug of the bisphosphonate classification by the health care provider.
   - **d.** The patient should supplement her diet with 1200 to 1500 mg of calcium with vitamin D orally twice daily.
8. A 48-year-old patient arrives at the clinic to discuss her perimenopausal symptoms. She states that her last menstrual period was 8 months ago, and before that they had been irregular. What is the most important nursing advice to give this patient?
   - **a.** Hormone therapy is only used for hot flashes and vaginal dryness.
   - **b.** The patient should be using some form of contraception to avoid pregnancy.
   - **c.** The patient should have a Dexa Scan to test for osteopenia.
   - **d.** At this time, herbal supplementation is probably best to relieve her perimenopausal symptoms.

OBJECTIVES

- Describe the effects of gonadal hormone supplementation on the hypothalamic anterior pituitary feedback loop.
- Describe the role of testosterone therapy in managing developmental problems related to primary and secondary male sex characteristics and in spermatogenesis.
- Differentiate common conditions for which androgen therapy and antiandrogen therapy are indicated.
- Describe patients for whom androgen therapy is particularly risky.
- Assess patients for therapeutic and adverse effects of androgen therapy.
- Categorize commonly prescribed medications that can impair male sexual function.
- Explain the nursing process, including patient teaching, related to drugs used to treat male reproductive disorders.

Reproductive health requires the production of adequate quantities of various hypothalamic, pituitary, and gonadal hormones as well as the appropriate hormone receptors. It requires normal development and patency of the reproductive tract. In addition, reproductive health implies that men and women at developmentally appropriate life stages are fertile (i.e., able to produce gametes [sperm or eggs]). Finally, reproductive health entails the ability to engage in sexual intercourse with ejaculation by the male.

The authors gratefully acknowledge the work of Karen Carmody, who updated this chapter for the eighth edition.

Alterations in male reproductive health reflect a wide range of developmental, endocrine, infectious, inflammatory, hypertrophic, malignant, and psycho-emotional processes. Review the introduction to this unit to gain a better understanding of ways in which reproductive health is affected, including anatomy and physiology, sperm production, regulation of male sexual functioning, and sexual intercourse.

The drug family most clearly associated with male reproductive processes is the androgens. Because synthetic anabolic steroids and antiandrogens affect male reproduction, they are also discussed.

SUBSTANCES RELATED TO MALE REPRODUCTIVE DISORDERS

Androgens

Androgens, or male sex hormones, control the development and maintenance of sexual processes, accessory sexual organs, cellular metabolism, and bone and muscle growth. **Testosterone** is the principal male sex hormone and is an anabolic steroid. It is the prototype of the androgen hormones, synthesized primarily in the testes and, to a lesser extent, in the adrenal cortex. In women, the ovaries synthesize small amounts of testosterone. In men, normal plasma concentrations of testosterone are 250 to 1000 ng/dL, with circadian fluctuations. Prototype Drug Chart 57-1 lists the natural and synthetic androgens and their dosages, uses, and considerations.

Pharmacokinetics Testosterone secretion is greater in men than in women in most stages of life. About 98% of circulating testosterone is bound to both sex hormone–binding globulin (SHBG) and albumin protein, leaving about 2% unbound, or circulating free in the plasma. It is this unbound portion that is biologically active. Estrogen elevates the production of sex hormone–binding globulin, resulting in more protein-bound testosterone in women than in men. The half-life of endogenous (naturally occurring) free testosterone in the blood is 10 to 20 minutes.

Exogenous (supplemental) testosterone is absorbed when taken orally, but because as much as 50% is metabolized on its first pass through hepatic circulation, high doses are needed to achieve effective plasma levels. Synthetic androgens have longer half-lives, so only synthetic androgens are available in oral formulations in the United States. Testosterone can be combined with esters to form esterified testosterone, in an oil base for intramuscular (IM) injection.

PROTOTYPE DRUG CHART 57-1

Testosterone

Drug Class

Androgen

Trade Names: Depo-Testosterone, First-Testosterone MC, Delatestryl

Pregnancy Category: X

CSS III

Dosage

Androgen replacement:

IM: 50-400 mg q2-4wk

Higher doses used to treat metastatic breast cancer

Contraindications

Pregnancy, nephrosis, hypercalcemia, pituitary insufficiency, hepatic dysfunction, benign prostatic hypertrophy, prostatic cancer, history of myocardial infarction, prepubertal status, non–estrogen-dependent breast cancer

Caution: Hypertension, hypercholesterolemia, coronary artery disease, gynecomastia, renal disease, seizure disorders; prepubescent patients, older adults

Drug-Lab-Food Interactions

Drug: Increases effects of anticoagulants; decreases effect with barbiturates, phenytoin, phenylbutazone; antagonizes calcitonin, parathyroid; corticosteroids exacerbate edema

Lab: Decreases blood glucose in diabetics; increases serum cholesterol, thyroid, liver function, hematocrit

Pharmacokinetics

Absorption: IM: Well absorbed

Distribution: PB: 98%

Metabolism: t½: 10-100 min

Excretion: In urine and bile

Pharmacodynamics

IM: Onset: UK

Peak: UK

Duration: cypionate/enanthate: 2-4 wk

Therapeutic Effects/Uses

To achieve normal androgen levels; to slow progress of estrogen-dependent breast cancers

Mode of Action: Develops and maintains male sex organs and secondary sex characteristics

Side Effects

Abdominal pain, nausea, diarrhea, constipation, hives, irritation at injection site, increased salivation, mouth soreness, increased or decreased libido, insomnia, aggressive behavior, weakness, dizziness, pruritus

FDA boxed warning for children exposed to gel: inappropriate enlargement of the genitalia (penis or clitoris), premature development of pubic hair, advanced bone aging, increased libido, and aggressive behavior

Adverse Reactions

Acne, masculinization, irregular menses, urinary urgency, gynecomastia, priapism, red skin, jaundice, sodium and water retention, allergic reaction, depression, habituation

Life-threatening: Hepatic necrosis, hepatitis, hepatic tumors, respiratory distress

CSS, Controlled Substances Schedule; *d,* day; *IM,* intramuscular; *min,* minute; *mo,* month; *PB,* protein-binding; *PO,* by mouth; *subQ,* subcutaneous; *t ½,* half-life; *UK,* unknown; *wk,* week.

Testosterone is excreted mainly in the urine as the metabolites androsterone and etiocholanolone. About 6% of the hormone is excreted unaltered in the feces. Synthetic androgens may be excreted as unaltered hormone or as metabolites. In some tissues the action of testosterone depends on its reduction to 5-alpha-dihydrotestosterone (DHT), whereas in other tissues testosterone itself is the active hormone. In the central nervous system, the metabolite estradiol affects hormonal action.

Pharmacodynamics Testosterone is responsible for the development of male sex characteristics. The biologic effects of testosterone may be mediated directly by testosterone or by its metabolites. Testosterone and dihydrotestosterone act as androgens by way of a single androgen receptor officially designated NR3A. The hormones bind to sites on certain responsive genes, causing a change to take place in the target cell. The effects of the testosterone depend on which receptor it activates and the tissues in which these effects occur. The manufacture of protein within the target cells results in the buildup of cellular tissue (anabolism), especially in muscles. This leads to development of secondary sex characteristics such as pubic hair growth, beard and body hair growth, baldness, deepening of the male voice, thickening of the skin, sebaceous gland activity, increased musculature, bone development, and red blood cell formation.

Fetal testes begin to produce testosterone during the first 3 months in utero. After birth until just before puberty, production is negligible. During puberty, production increases rapidly and continues until later adulthood. As men age, the number of Leydig cells decreases, sperm production declines, and luteinizing hormone (LH) and follicle-stimulating hormone (FSH) levels rise. Levels of unbound testosterone are reduced in older men to one-third to one-fifth the peak value. If men experience osteoporosis and anemia, and if their testosterone levels are ≤300 ng/dL, testosterone replacement therapy should be considered.

Indications for Androgen Therapy

Table 57-1 lists the natural and synthetic androgens with their dosages, uses, and considerations. The most common clinical use is for androgen deficiency in males, specifically hypogonadism, replacement therapy for testicular failure in adult males, and delayed puberty in adolescents. Occasionally it is used to slow the decline of patients with certain muscle wasting diseases such as COPD and AIDS.

Hypogonadism. The clearest indication for exogenous androgen therapy is **hypogonadism.** Male hypogonadism is a defect of the reproductive system that results in failure of

TABLE 57-1 ANDROGENS (CSS-III)

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Natural Androgens		
testosterone		
Testoderm scrotal patch	Discontinued in the U.S. Generic versions may still be available.	Androgen replacement, delayed puberty, carcinoma of the breast.
Androderm, Testoderm TTS	Transdermal patch: 5 mg/24 h; apply to nongenital skin; avoid bony areas	Started at full dose and adjusted according to tolerance and therapeutic response.
AndroGel/Testim 1 & 1.62%	1% Gel: 50-100 mg once daily	Less skin irritation with gel than patch. Pregnancy category: X; PB: 98%; t½: 10-100 min
Fortesta 2%	2% Gel: 40-70 mg once daily	
Axiron	Axillary Solution: 60-180 mg/day	
Striant	Buccal: 30 mg twice daily	
Testopel 75 mg/pellet	SubQ implantable pellets: 150-450 mg q3-6mo	
testosterone cypionate (Depo-Testosterone)	IM: 200-400 mg q3-4wk	Androgen replacement, delayed puberty. Therapy generally lasts 3-4 y. Pregnancy category: X; PB: 98%; t½: 8 days
testosterone enanthate (Delatestryl)	IM: 50-400 mg q2-4wk	Androgen replacement, delayed puberty. Pregnancy category: X; PB: 98%; t½: 10-100 min
Synthetic Androgens		
danazol	PO: 100-800 mg/d in 2 divided doses initially	Endometriosis, fibrocystic breast disease, hereditary angioedema. Initial doses are gradually reduced on an individual basis. Pregnancy category: X; PB: UK; t½: 4.5 h
fluoxymesterone (Androxy)	PO: 5 mg 1-4 times/day	Androgen deficiency, carcinoma of the breast. Pregnancy category: X; PB: 98%; t½: 29.2 h
methyltestosterone (Android, Methitest, Testred)	PO: 10-50 mg/d in divided doses initially, reduced for maintenance	Androgen deficiency, carcinoma of the breast. Pregnancy category: X; PB: UK; t½: 2.5-3.5 h
Anabolic Steroids		
oxandrolone (Oxandrin)	A: PO: 2.5-20 mg/d, divided C: PO: <0.1 mg/kg/d	Cachexia, delayed growth/puberty, osteoporotic pain, short stature, Turner's syndrome, alcoholic hepatitis. Pregnancy category: X; PB: 94%-97%; t½: 9.4 h

C, Child; *d,* day; *h,* hour; *IM,* intramuscular; *min,* minute; *mo,* month; *PB,* protein-binding; *PO,* by mouth; *RBC,* red blood cell; *subQ,* subcutaneous; *t½,* half-life; *UK,* unknown; *wk,* week; *y,* year.

the testes to produce testosterone, sperm, or both. Deficiency of sex hormones can result in defective primary or secondary sexual development. Defective sperm development can result in infertility. Hypogonadism is either primary, reflecting testicular abnormality, or secondary, reflecting hypothalamic or pituitary failure. A combination of disorders can also occur. Inadequate pituitary function will severely affect young boys and results in lack of secondary sex characteristics and infertility. Adult men may experience lack of libido, testicular atrophy, impotence, decreased bone density, loss of muscle tone, increased hair growth, or the onset of vasomotor flushing may occur.

The timing and extent of treatment depend on the clinical manifestations. Because accelerated bone maturation can lead to premature closure of bone epiphyses and short stature, androgen therapy should be used cautiously in children and only by specialists aware of the adverse effects on bone maturation. Skeletal maturation must be monitored every 6 months by x-ray of the hand and wrist. Artificial induction of puberty is undertaken only after boys reach age 15 to 17 years and hypothalamic and pituitary function has been assessed. A 4- to 6-month trial of androgen therapy is implemented, followed by a like period of rest for reevaluation. If prolonged therapy is required, testosterone cypionate or testosterone enanthate is used, 50 to 400 mg IM every 2 to 4 weeks. It should be given deep in the gluteal muscle. Inspect vials visually for particulate matter and discoloration before administration. Warm and shake the vial to dissolve any crystals that may have formed during storage. It takes 3 or 4 years for sexual development to occur. Plasma testosterone levels should be monitored and dosages adjusted as needed to maintain normal levels. If the serum testosterone level is below the normal range, the provider will adjust the dose upward. Therapy may be lifelong.

Some young, hypogonadal men are able to resolve erectile dysfunction with testosterone replacement therapy by way of oral, parenteral, or direct injection of drugs into the penis. These therapies may be associated with hypotension, dizziness, pain, and priapism; some of these drugs can cause hepatotoxicity. Given the success and high efficacy of oral erectile dysfunction therapy, discussed later, the use of these medications for adult hypogonadism has decreased markedly.

Testosterone may be administered buccally, orally, transdermally, or parenterally. The selection of an androgen or anabolic steroid depends on the balance of growth and sexual maturation desired and on the preferred route of administration. A buccal muco-adhesive system (Striant) is available at a 30-mg dose every 12 hours. Advise the patient to place the rounded side surface of the system against the gum above an incisor tooth and hold firmly in place with finger over lip and against product for 30 seconds. To remove, slide gently downwards toward tooth to avoid scratching gums. Sites must be rotated with each application. If the product falls off within the 12-hour dosing interval or falls out of position within 4 hours before next dose, remove and apply a new system. The patient should not chew or swallow the tablet. Advise the patient to regularly inspect gums where the system has been applied. With the exception of the buccal system, androgens are considered controlled substances Schedule III.

Many brands of testosterone transdermal patches are available. Testoderm patches are applied to the scrotum; scrotal skin is about five times more permeable than normal skin, and Testoderm will not achieve desired serum concentrations if applied to other skin sites. Serum concentrations of testosterone maximize after 2 to 4 hours, returning to baseline 2 hours after patch removal. Serum concentrations of testosterone approach those of normal males and reach a plateau after 3 to 4 weeks. Testoderm TTS patches achieve adequate serum concentrations when applied to the arm, back, or upper buttocks. Androderm patches can be applied to any healthy skin site other than the scrotum or bony areas. Daily application of two Androderm 2.5-mg skin patches at 10 PM results in serum testosterone concentrations approaching those of healthy young men. The first day of dosing results in morning serum testosterone concentrations within the normal range. There is no testosterone accumulation with continued use. After removal of Androderm, hypogonadal status returns within 24 hours. Keep testosterone gel out of reach of children.

An underarm solution (Axiron) is applied to one or both axillary areas at the same time each day. The patient should not apply Axiron to the genitals. These skin application products can be transferred to others through personal contact with skin or clothing. The treatment eliminates the need for injections and provides circadian fluctuations in dosage.

Other Uses. Other uses of androgens include treatment of refractory anemia in men and women, hereditary angioedema, tissue wasting associated with severe or chronic illness, advanced carcinoma of the breast in women, and endometriosis. The effectiveness of androgens for treatment of **cryptorchidism** (undescended testis) and impotence has not been established. Androgens may be used in combination with estrogens for management of severe menopausal symptoms in women.

Side Effects. Hypogonadal men on androgen therapy may experience frequent erections or **priapism** (painful, continuous erection), **gynecomastia** (mammary gland enlargement in men), or urinary urgency. Continued use of androgens by normal men can halt **spermatogenesis** (formation of spermatozoa). The sperm count may be low (**oligospermia**) for 3 or more months after therapy is stopped.

Other side effects of androgen therapy include abdominal pain, nausea, insomnia, diarrhea or constipation, hives or redness at the injection site, increased salivation, mouth soreness, and increased or decreased sexual desire. Advise the patient to notify the health care provider if side effects persist, worsen, or are bothersome.

Adverse Reactions. Androgen therapy may cause hypercalcemia by stimulating bone resorption in patients with breast cancer or immobilized patients. The drug should be discontinued and appropriate measures instituted if signs of hypercalcemia occur including: nausea and vomiting, lethargy, decreased muscle tone, polyuria, and increased urine and serum calcium.

Virilization refers to the development of male secondary sex characteristics in women or hypogonadal males. Such characteristics include growth of facial hair, acne and skin oiliness, and vocal huskiness. Menstrual irregularities or amenorrhea, suppressed ovulation or lactation, baldness or increased hair growth (**hirsutism**), and hypertrophy of the clitoris may develop in women undergoing androgen therapy. Although most adverse effects slowly reverse themselves after short-term therapy is completed, vocal changes may be permanent. With long-term therapy, as in the treatment of breast cancer, adverse effects may be irreversible.

Children may experience profound virilization as well as impaired bone growth. During pregnancy, androgens can cross the placenta and cause masculinization of the fetus. Virilization can occur in those secondarily exposed to testosterone gel and may cause teratogenic effects in fetuses. Women and children should not handle the gel and should avoid contact with application sites in men using testosterone gel.

Less frequent adverse effects include dizziness, weakness, changes in skin color, frequent headaches, confusion, respiratory distress, depression, pruritus, allergic skin rash, edema of the lower extremities, jaundice, bleeding, paresthesias, chills, polycythemia, muscle cramps, and sodium and water retention. Hepatic carcinoma can occur in patients who have received selected androgens for long-term therapy.

Serum cholesterol may become elevated during androgen therapy. Other alterations in laboratory tests include increased hematocrit, altered thyroid and liver function tests, and elevated urine 17-ketosteroids (a by-product of the breakdown of androgens). Rare complications of long-term therapy include hepatic necrosis, hepatic peliosis (blood-filled cysts), hepatic tumors, and leukopenia.

Contraindications. Androgen therapy is contraindicated during pregnancy and in individuals with nephrosis or the nephrotic phase of nephritis, hypercalcemia, pituitary insufficiency, hepatic dysfunction, benign prostatic hypertrophy, prostate cancer, or history of myocardial infarction. Men with breast cancer are not treated with androgens, nor are women whose breast cancer is not estrogen-dependent.

Caution must be exercised when using androgen therapy in individuals with hypertension, hypercholesterolemia, coronary artery disease, renal disease, or seizure disorder. It is used with caution in infants and prepubertal children because of the potential for growth disturbances and in older men because of their increased risk for benign prostatic hypertrophy and prostate cancer.

Drug Interactions. Androgens potentiate the effects of oral anticoagulants, necessitating a decrease in anticoagulant dosage. Androgens antagonize calcitonin and parathyroid hormones. Because androgens can decrease blood glucose in patients with diabetes, dosages of insulin or other antidiabetic agents may need to be reduced. Concurrent use of corticosteroids exacerbates the edema that can occur with androgen therapy. Barbiturates, phenytoin, and phenylbutazone decrease the effects of androgens.

Anabolic Steroids

Anabolic steroids, or anabolic-androgenic steroids (AAS), are a class of steroid hormones related to the hormone testosterone. They increase protein synthesis within cells, which results in the buildup of cellular tissue (**anabolism**), especially in muscles. Anabolic steroids also have androgenic and virilizing properties, including the development and maintenance of masculine characteristics such as the growth of the vocal cords and body hair. The American College of Sports Medicine notes that AAS, combined with sufficient diet, can contribute to increased body weight, often as lean mass, and that the gain in muscular strength achieved through high-intensity exercise and proper diet can be additionally enhanced by the use of AAS in some individuals.

Testosterone precursors available as nutritional supplements include androstenediol, androstenedione, and dehydroepiandrosterone (DHEA). Older teens are the heaviest users, but more than one-half million junior high school students use them. Marketed as "sport supplements" or "teen formulas," they can be purchased without a prescription in stores and on the Internet. A sudden dramatic increase in weight and body size, increased acne, and changes in mood and behavior can be signs of exogenous anabolic steroid use. Individuals using anabolic steroids may become more aggressive and physical. Health risks can result from long-term use or excessive intake of anabolic steroids; these effects include increased low-density lipoprotein (bad) cholesterol and decreased high-density lipoprotein (good) cholesterol, acne, high blood pressure, liver damage, and dangerous changes in the structure of the left ventricle of the heart. Adverse effects may not be recognized until years later.

Two other steroids that have gained popularity, especially with athletes, are human chorionic gonadotropin (hCG, Pregnyl, Novarel, Ovidrel) and tetrahydrogestrinone (THG). HCG is a hormone used to treat infertility and stimulate testosterone production. THG is a potent androgen developed to escape urine detection. It is not approved by the U.S. Food and Drug Administration (FDA) and is not legally marketed. All major athletic organizations prohibit the use of anabolic steroids, but their continued use despite bans has led to "anti-doping" investigations and punitive action.

Nursing Process
Patient-Centered Collaborative Care

Androgens

Assessment

- Assess the reason for androgen therapy and patient's perception of it. If delayed puberty is the indication, assess patient and family attitudes about the condition.
- Monitor patient's weight, blood pressure, liver and thyroid function, hemoglobin and hematocrit, creatinine, clotting factors, glucose tolerance, serum lipids

and electrolytes, and blood count before and throughout treatment. Note the presence of liver or endocrine dysfunction, or elevation in blood pressure.

- Note concomitant anticoagulant therapy.
- When a prepubertal child is treated, obtain hand and wrist x-rays before, every 6 months during, and after treatment to monitor growth.
- Appraise patient's expressive affect during therapy, particularly aggressiveness in patients taking large doses. Self-concept is an important consideration in the patient on androgen therapy, particularly in children with delayed puberty and in women.

Nursing Diagnoses

- Disturbed body image related to growth delay
- Delayed growth and development related to androgen deficiency
- Situational low self-esteem related to growth delay and/or virilizing effects of androgen therapy
- Sexual dysfunction related to androgen deficiency
- Ineffective sexuality pattern related to antiandrogen therapy and or delayed puberty
- Readiness for enhanced knowledge related to therapeutic regimen management

Planning

- Through collaboration, patient agrees to adhere to prescribed regimen for taking medication and for monitoring; use medication appropriately; report adverse effects immediately; and maintain positive self-concept during long-term treatment.

Patient Teaching

General

- Collaborate with patient and family on proper administration of medications, their reasons for use, and potential undesired effects. Review which effects warrant prompt medical attention (e.g., urinary problems, priapism, respiratory distress).
- Advise patient that an intermittent approach to treatment allows for monitoring of endocrine status between courses of androgen therapy. Explain need to return to health care facility for monitoring, and determine patient's ability to do so. Arrange social service referrals if necessary.
- Counsel family pursuing treatment for a child with delayed puberty about range of normal development.
- Advise patients being treated for tissue wasting to reduce environmental stressors and promote rest and relaxation, because stress hormones are catabolic.
- Encourage patient to monitor muscle strength during treatment.

Self-Administration

- Instruct patient to take oral androgens with food to decrease gastric distress.

Side Effects

- Coach patient about good skin hygiene to decrease severity of acne.
- Urge men undergoing androgen therapy to report priapism promptly so drug dosage can be reduced to avoid subsequent erectile dysfunction.
- Instruct men to report decreased urinary stream promptly so they can be evaluated for prostatic hypertrophy.

Diet

- Assess and review, as needed, nutritional intake of individuals with anemia, osteoporosis, or tissue wasting to ensure adequate intake of essential nutrients.
- Council patient to record body weight several times per week. Restrict sodium if edema develops.
- Advise patients with elevated serum calcium of the need to drink 2 L/day or more of fluid to prevent kidney stones. Individuals on bed rest need range-of-motion exercises, whereas ambulatory patients need to engage in active weight bearing. Hypercalcemia needs prompt medical attention, because it can lead to cardiac arrest.

Cultural Considerations

- Assess how patient's cultural group regards expression of sexuality.
- Ascertain any culturally defined expectations about male-female or male-male relationships, including health care relationship.
- Ask if patient has restrictions related to sexuality, exposure of body parts, or discussion of sexual functioning.

Evaluation

- Monitor patient's ability to adhere to treatment regimen and response to prescribed drugs. Ability to adhere to treatment plan and discuss treatment and effects knowledgeably suggests that teaching has been effective and that patient accepts treatment.
- Ask patient about therapeutic and adverse drug effects on follow-up visits. Monitoring of weight, blood pressure, and laboratory tests will continue throughout therapy, with alterations in the plan of care as needed.
- Periodically assess children and women who experience virilizing effects or acne for ability to cope with these changes and maintain a positive self-concept.
- Assess sexual function when appropriate.

Antiandrogens

Antiandrogens, or androgen antagonists, block the synthesis or action of androgens (Table 57-2). These drugs are used in the treatment of benign prostatic hypertrophy, advanced prostatic cancer, and as hormonal therapy in the treatment of endometriosis. They may also be used to treat male-pattern baldness, acne, hirsutism, virilization syndrome in women,

TABLE 57-2 ANTIANDROGENS

MECHANISM	DRUGS
Elevation of Gn-RH level	goserelin acetate (Zoladex) nafarelin acetate (Synarel) leuprolide acetate (Lupron, Viadur, Eligard)
Inhibition of testosterone synthesis	ketoconazole (Nizoral)
Blocks conversion of testosterone to dihydrotestosterone	finasteride (Proscar)
Receptor inhibitors	flutamide (Eulexin) bicalutamide (Casodex) spironolactone (Aldactone)

Gn-RH, Gonadotropin-releasing hormone.

and precocious puberty in boys, although their effectiveness is not well established. The effectiveness of these drugs to inhibit the sex drive of men who are sex offenders is controversial and not well documented.

Gonadotropin-releasing hormone (Gn-RH), or a synthetic analogue such as leuprolide, is the most effective inhibitor of testosterone synthesis. When such agents are given over time, LH and testosterone levels fall. Normally, Gn-RH is released in a pulsatile fashion, but the sustained activity of leuprolide leads to decreased production of FSH and LH. In the male, this activity stops testosterone production in the testis. In the female, it stops estrogen production in the ovaries. This drug should not be used in combination with herbal or dietary supplements, like black cohosh, DHEA, or chasteberry.

Ketoconazole, an antifungal drug, has testosterone-suppressing effects similar to those of Gn-RH analogues when given at doses higher than those required for antifungal activity. The mechanism of action of this non–Gn-RH drug is unclear. Gn-RH analogues act directly through their impact on testosterone production for the treatment of prostate cancer.

Flutamide is an oral nonsteroidal antiandrogen drug used as an antihormonal agent in the treatment of metastatic prostate cancer. It is most effective when used simultaneously with LHRH agonists such as leuprolide acetate. When used alone, the best response is seen in untreated patients. Flutamide is not effective in treating other hormonally dependent diseases such as breast cancer or benign prostatic hypertrophy. Flutamide competes with androgens at androgen receptor sites in the prostate gland, blocking the conversion of testosterone to dihydrotestosterone. By doing so, it prevents the androgens from stimulating the prostate cancer cells to grow. Men receiving flutamide show elevations in plasma LH and testosterone levels. Bicalutamide (Casodex) is structurally related to flutamide but has a long plasma half-life that allows once-daily dosing, compared with three times daily for flutamide. In addition, bicalutamide is more selective for the peripheral androgen receptor and has less activity at the central androgen receptor on the hypothalamic-pituitary axis.

Spironolactone (Aldactone) is a weak potassium-sparing diuretic used primarily to treat high blood pressure, heart failure, and ascites in patients with liver disease. While not FDA-approved indications, spironolactone has been used to treat acne vulgaris, polycystic ovary syndrome, and female hirsutism. Dosage ranges from 25 to 200 mg/day in divided doses with a maximum adult dose of 400 mg/day. It is a common component in hormone therapy for male-to-female transsexual and transgender surgical patients. It is also used for treating acne in women and can be used as a topical medication for treatment of male pattern baldness.

Finasteride (Propecia/Proscar), a synthetic compound, inhibits conversion of testosterone to 5-alpha-dihydrotestosterone (DHT). This orally active agent decreases the concentration of dihydrotestosterone in plasma and in the prostate without elevated plasma concentrations of LH or testosterone. Finasteride is used to treat benign prostatic hypertrophy (BPH) and male pattern baldness (MPB). The recommended 5-mg daily dose of Proscar for BPH needs to be reevaluated at 6 months and periodically thereafter. The 1-mg dose of Propecia for MPB is taken once a day for 12 months. Continued treatment is recommended for sustained results. Following discontinuation of therapy, reversal of effect is typically seen within 1 year. Adverse reactions include impotence, decreased libido, and decreased ejaculate. Women of childbearing age must not use finasteride and should not handle crushed or broken tablets because the active ingredient may cause abnormalities of a male fetus's sex organs.

Drugs Used in Other Male Reproductive Disorders

Delayed Puberty

A height of two or more standard deviations below the mean for age and sex occurs in 2.5% of normal children. Delay in growth may be a normal part of the maturation process. However, the cause could be androgen deficiency or a deficiency of growth hormone. Secretion of Gn-RH, LH, or FSH is insufficient in up to 5% of cases of **delayed puberty.** Treatment is not initiated before 14 years of age and after a full evaluation. Therapy for 3 to 6 months or less before epiphyseal closure may result in linear growth without adverse permanent effects on hypothalamic, pituitary, or gonadal maturation.

Pituitary, Thyroid, and Adrenal Disorders

Inadequate pituitary function can be another cause of hypogonadism. Menotropins (Menopur, Pergonal, Repronex) are purified combination preparations of the human pituitary gonadotropins, FSH and LH. These drugs are indicated when both LH and FSH levels are low. They encourage spermatogenesis in males with primary or secondary hypogonadism and induce ovulation in anovulatory females. To induce ovulation, Menotropins is given concomitantly with hCG 5,000 to 10,000 IU IM twice a week for at least 3 months. The drug will stimulate testosterone production in men to encourage spermatogenesis when injected three times a week for 4 to 9 months to ensure adequate spermatozoa production. One ampule of Menotropins contains 75 international units (IU) each of LH and FSH. The initial dose is 150 IU SQ/IM once daily for 5 days. Adjust subsequent dose to individual response at intervals no less than every 2 days and not exceeding 75 to 150 IU/adjustment; maximum dose is 450 IU/day. Use lower abdomen (alternating sides) for SQ administration. It must be used immediately after reconstitution and protected from light. Advise patients to discard unused medication. Adverse effects include nausea, vomiting, diarrhea, gynecomastia, and fever.

Inadequate thyroid and adrenal gland function can also affect sexuality. **Hypothyroidism,** a deficiency in thyroid hormone, can be the result of insufficient thyroid hormone production or resistance to its effects at the target organs. The problem can be congenital or acquired. It can cause **inhibited sexual desire** (decreased or lack of interest in sexual activity) and erectile dysfunction. In **Addison's disease**, there is a deficit of both cortisol and the mineralocorticoid aldosterone. Men with Addison disease may experience inhibited sexual desire, erectile dysfunction, or diminished fertility. Both hypothyroidism and Addison's disease are conditions highly responsive to replacement therapy with the appropriate hormones. (Refer to Chapter 51 for discussion of Addison's disease.)

Sexual Dysfunction

Sexual dysfunction is the inability to experience sexual desire, erection, ejaculation, and/or detumescence—the phases of the sexual response cycle. Inhibited sexual desire can result from androgen deficiency, an affective disorder, or discord in the sexual relationship. Many drugs can cause sexual dysfunction (Table 57-3).

Ejaculatory dysfunction (impaired ejection of seminal fluid from the male urethra) can be psychogenic or a result of drug therapy, androgen deficiency, or sympathetic degeneration. Failure of detumescence (reduction of penile engorgement) is most commonly caused by penile disease, systemic disease, trauma, or adverse effects of drugs. Individuals who experience premature ejaculation related to excessive anxiety about sexual intercourse may be helped by treatment with one of the many antidepressants alone or in conjunction with psychotherapy.

Erectile dysfunction (ED) is the inability to achieve or maintain an erection satisfactory for sexual performance. ED happens when not enough blood flows to the penis during sexual stimulation. This may be caused by psychoemotional problems, diabetes, hypertension, lower urinary tract symptoms, a history of pelvic surgery, vascular insufficiency, neurologic disorders, androgen deficiency or resistance, or diseases of the penis. Erectile dysfunction caused by vascular insufficiency is occasionally treated on a short-term basis by local vasoactive drugs, including papaverine, phentolamine, prostaglandin E, and nitroglycerin. Other medication options for the treatment of ED include oral medications, drugs injected into the penis, intraurethral alprostadil, or the male hormone testosterone.

TABLE 57-3 DRUGS THAT CAUSE SEXUAL DYSFUNCTION IN MALES

DRUG CATEGORY	DRUGS OR DRUG FAMILIES
Anticholinergics	atropine
	scopolamine
	benztropine
	trihexyphenidyl
Antidepressants	tricyclic antidepressants
	monoamine oxidase inhibitors
	selective serotonin reuptake inhibitors
Antihistamines	diphenhydramine
	hydroxyzine
Antihypertensives	centrally acting alpha$_2$ agonists
	alpha- and beta-receptor blockers
	diuretics
	angiotensin-converting enzyme inhibitors
Antipsychotics	phenothiazines
	thioxanthenes
	butyrophenone
Antiulcer drugs	cimetidine
	ranitidine
	famotidine
Sedatives and recreational drugs	alcohol
	barbiturates
	diazepam
	chlordiazepoxide
	cannabis
	cocaine
	opiates
	methadone
Others	aminocaproic acid
	baclofen
	steroids
	ethionamide
	digoxin
	chemotherapeutic agents
	lithium

A class of drugs called phosphodiesterase (PDE) inhibitors facilitates erections by enhancing blood flow to the penis. PDE-5 inhibitors are currently the most commonly used medical treatment for ED. These medications have a high success rate, are easy to use, and often result in erection when sexually stimulated. The PDE-5 inhibitors currently approved by the FDA are sildenafil (Viagra/Revatio), tadalafil (Cialis), vardenafil (Levitra/Staxyn) and avanafil (Stendra). PDE inhibitors are taken before sexual activity with variations in effective start time and duration of benefit (Table 57-4).

Nitroglycerin and other nitrate medications used to treat heart disease can cause a significant decrease in blood pressure when taken with PDE-5 inhibitors. Therefore, this class of drugs is contraindicated for use by any patient using organic nitrates in any form. Patients with a prescription for PRN sublingual nitroglycerin can take PDE inhibitors, but should still be cautioned about taking them concomitantly. Organic nitrates include nitroglycerin, isosorbide

TABLE 57-4 PDE-5 INHIBITORS FOR ERECTILE DYSFUNCTION

GENERIC (BRAND)	ONSET/ DURATION	SIDE EFFECTS	DRUG INTERACTIONS
sildenafil 20 mg (Viagra, Revatio); works best on an empty stomach	Onset: 30-60 min Duration: 4 h	• Abdominal symptoms, such as diarrhea, heartburn, and upset stomach • Abnormal vision, such as blurring, sensitivity to light and blue-green color tint • Dizziness • Flushing • Headache • Nasal congestion	• Nitrates: isosorbide, nitroglycerin, amyl nitrate, butyl nitrate • Alpha blockers: alfuzosin, doxazosin, prazosin, tamsulosin, terazosin, amiodarone • Antiinfective agents: fluconazole, itraconazole, ketoconazole, clarithromycin, moxifloxacin, erythromycin • Cardiac medications: disopyramide, procainamide, quinidine, sotalol, thioridazine, verapamil • HIV protease inhibitors: atazanavir, indinavir, ritonavir, saquinavir • Other medications: methadone, pimozide, haloperidol
tadalafil 5 mg (Cialis), avanafil 50-200 mg; not affected by food	Onset: 15-60 min Duration: 24-36 h		
vardenafil 5 mg (Levitra, Staxyn); less effective with a high-fat meal	Onset: 25-30 min Duration: 4-5 hours Use once in 24 h		

h, Hour; *min,* minute.

mononitrate, isosorbide nitrate, pentaerythritol tetranitrate, erythrityl tetranitrate, isosorbide dinitrate/phenobarbital, and illicit substances (amyl nitrate/nitrite, butyl nitrate). Sildenafil is contraindicated in patients with significant cardiovascular disease or individuals who have anatomic deformities or conditions predisposing them to priapism.

Studies have shown that vardenafil (Levitra) and tadalafil (Cialis) are safer for patients with heart failure or a history of myocardial infarctions. Like sildenafil, they are contraindicated if the patient is taking nitrate-containing medications. Common side effects of these drugs are headache (most common), dyspepsia, nasal congestion, and nasopharyngitis. Other rare side effects can also occur, and the patient should be taught about them. These effects include blurred vision, photosensitivity, changes in color perception (especially blue and green), and urinary tract symptoms such as frequency or painful urination, and cloudy or bloody urine. Patients are instructed to notify their health care provider of any side effects they experience.

The PDE-5 inhibitors interact with grapefruit juice and grapefruit products by increasing the amount of the PDE-5 inhibitor absorbed, thereby increasing the risk of side effects. Many medications may interact with PDE-5 inhibitors, so be sure to obtain a complete list of medications taken by the patient.

Certain drugs are often abused by individuals seeking a heightened sexual experience. Amyl nitrate is commonly believed to be an aphrodisiac. Sudden death, myocardial infarction, and methemoglobinemia have been reported with its use. Cantharides (Spanish fly) causes bladder and urethral irritation, accounting for its use as a sexual stimulant. Permanent penile damage has been reported with its use.

SAFETY: Preventing Medication Errors

Do not confuse …

- **Lupron Depot-3 Month** with **Lupron Depot-Ped**
- **Testoderm** with **Testoderm TTS**
- **anabolic steroids** with **corticosteroids**

Natural Products. To self-treat sexual problems or to enhance their sexual performance, consumers use a wide variety of herbs and plant-derived compounds (phytochemicals). Despite new science-based therapies, men are attracted to phytochemicals because they are easy to obtain and may be cheaper than prescription medications, therapies, procedures, or surgeries not covered by insurance. Consumers may perceive natural products as providing health benefits beyond sexual performance because they can be purchased at nutrition centers or health food stores. Common herbs used for sexual health and performance include yohimbine, ginseng, damiana, ginkgo biloba, saw palmetto, muira puama, and Tribulus terrestris. With the exception of yohimbine, which has been scientifically studied, the other compounds do not have benefits proven by research. Their benefits appear to reflect popular or cultural beliefs. Reports in health magazines and advertising are anecdotal and based on a small number of users or health care professionals.

Yohimbine, which is obtained from the bark of the African yohimbe tree, is an alpha-adrenergic antagonist that affects both the central and peripheral nervous system. Studies have shown that men experience a positive effect or improvement in erection. The side effects are headache, hypertension, sweating, anxiety, and sleeplessness. Men who have cardiovascular, neurologic, or psychological problems should not take yohimbine.

Saw palmetto is a popular herbal remedy used to treat symptoms related to BPH and can help shrink enlarged prostate glands. Although effective in the treatment of prostate enlargement, it has not been shown to exert a positive effect on sexual response in men unless erections are inhibited by an enlarged prostate gland. In fact, saw palmetto may reduce androgen action and have a negative effect on sexual response.

Ginkgo biloba leaves have been shown to treat peripheral vascular disease and enhance cerebral blood flow. Research suggests that ginkgo biloba may reduce antidepressant–induced sexual dysfunction caused by selective serotonin reuptake inhibitors. It is not known how it achieves these effects, and further research is needed to substantiate its use. Similarly, ginseng has been shown to improve sexual functioning in animals, but research in humans is contradictory, and further human research is warranted.

Non–Sexually Transmitted Infections

Drugs used to treat acute or chronic prostatitis, orchitis, or epididymitis are the same as those used to treat urinary tract infections (see Chapter 34).

Benign Prostate Hyperplasia

As a man ages, the glandular units in the prostate gland begin to undergo tissue hyperplasia (abnormal increase in the number of cells), resulting in prostatic hypertrophy (enlargement of the gland). The exact cause of BPH is unknown, but its development is almost universal in older men. The enlarged prostate gland contributes to overall lower urinary tract symptoms either through direct bladder outlet obstruction or from resistance within the enlarged gland itself. The man experiences storage and/or voiding disturbances, such as a sensation of bladder fullness, frequency, nocturia, hesitation when trying to begin urinating, dribbling of urine, and erectile dysfunction. Although BPH is not a life-threatening condition, the impact of symptoms on quality of life can be significant. Because these are the same symptoms that prostate cancer may cause, the patient should have a prostate-specific antigen (PSA) blood test and may undergo a prostate biopsy to make sure no cancer is present. Traditionally, the primary goal of treatment has been to alleviate bothersome symptoms. More recently, treatment has also been focused on the alteration of disease progression and prevention of complications. A variety of pharmacologic classes are employed, including alpha-adrenergic antagonists (alpha-blockers), 5-alpha-reductase inhibitors (5-ARIs), anticholinergics, phytotherapeutics, and (most recently) the PDE-5 inhibitor tadalafil. Choosing the correct medical treatment for BPH is complex (Table 57-5). The American Urological Association 2010 Guidelines are a useful reference on the effective evidence-based management of lower urinary tract symptoms caused by BPH. The guidelines advise a discussion of benefits and risks of each recommended treatment alternative (e.g., watchful waiting, medical, surgical, or minimally invasive surgical treatments). The choice of treatment is reached in a shared decision-making process between provider and patient.

With initiation of drug therapy, the patient should be followed every 1 to 3 months, depending on the class of medication chosen, to assess success and inquire about side effects. The patient with an enlarged prostate should avoid medications that can cause urinary retention, such as anticholinergics, antihistamines, and decongestants.

TABLE 57-5 MEDICATIONS USED FOR TREATMENT OF BPH

GENERIC (BRAND)	ROUTE AND DOSAGE	SIDE EFFECTS
5-Alpha-Reductase Inhibitors		
finasteride (Proscar)	PO: 5 mg	Decreased libido, erectile dysfunction
duastride (Avodart)	PO: 0.5 mg	
Safety in Administration		
Caution patients that women of childbearing age must not handle crushed or broken tablets due to possible absorption and potential risk to male fetus; immediately wash contact area with soap and water if contact occurs. Inform patients of increase in high-grade prostate cancer in men treated with 5α-reductase inhibitors indicated for BPH treatment. Inform patients that volume of ejaculate may be decreased and impotence/decreased libido may occur. Instruct to promptly report to physician any changes in breasts (lumps, pain, or nipple discharge).		
Alpha-Adrenergic Blocking Agents		
tamsulosin (Flomax)	PO: 0.4 mg/d 30 min after a meal; titrate up to 0.8 mg/d	Postural hypotension, dizziness, fatigue
doxazosin (Cardura)	PO: Start 1 mg/d h.s.; titrate up to 8 mg/d h.s.	
terazosin (Hytrin)	A: PO: Start 1 mg/d h.s.; titrate up to 10 mg/d *max:* 20 mg/d	
alfuzosin (Uroxatral)	PO: 10 mg/d after a meal	
silodosin (Rapaflo)	PO: 8 mg/d with a meal	
Safety in Administration		
Alpha-adrenergic blocking agents are also used to control blood pressure. To avoid hypotensive episode, advise using at bedtime and reconcile all medications taken before adding another antihypertensive drug. Instruct patient to take medication with food. Counsel about possible symptoms of postural hypotension (dizziness); caution about driving, operating machinery, or performing hazardous tasks. Inform patient that orgasm with reduced or no semen does not pose a safety concern and is reversible when drug is stopped. Advise patient to notify ophthalmologist about use before cataract surgery or other eye procedures.		
PDE-5 Inhibitors		
tadalafil (Cialis)	PO: 5 mg	See Table 57-4
Safety in Administration		
Should not be used by patients taking nitrates such as nitroglycerin because the combination may trigger an unsafe drop in blood pressure. Also tadalafil should not be used with alpha-blockers for the treatment of BPH because the combo therapy has not been adequately studied and may increase the risk of lowering blood pressure.		

d, Day; *h.s.,* at bedtime; *min,* minute.

Malignant Tumors

Prostatic cancer accounts for about 10% of all cancer deaths among American men. Most prostatic cancers are adenocarcinomas. Metastasis to lymph nodes, bone, lungs, liver, and adrenal glands is common. Prostatic cancer is often asymptomatic, but urinary obstruction is commonly the first sign. Treatment may include a combination of surgical resection, cryotherapy, antiandrogen administration, radiation therapy, chemotherapy, and pain management.

Testicular tumors peak in early adulthood. They include malignant germinal cell tumors and benign Leydig or Sertoli cell tumors. Treatment depends on the type and stage of tumor. Surgical excision, radiation therapy, and chemotherapy are used alone or in combination.

Approximately 1% of breast cancer cases occur in men, most commonly after age 60 years. Treatment, which is similar for men and women, entails surgery, radiation therapy, chemotherapy, and endocrine therapy. Carcinoma of the penis represents less than 1% of all malignancies among men. In situ, treatment entails local excision, radiation therapy, and local application of 5-fluorouracil cream or solution. Invasive carcinoma is treated by surgical resection of the penis and involved nodes. Radiation and chemotherapy follow as needed.

CRITICAL THINKING CASE STUDY

MT, age 16 years, is a high school junior who is 59.3 inches tall and weighs 126 lb. He is having increased feelings of discomfort about not fitting in with the other students at school because he has not yet begun sexual maturation. He is a good student and an accomplished violinist in the school orchestra. His father states that he also was a "late bloomer," but both parents are concerned about MT's increasing social withdrawal and seem determined to seek medical intervention for him. The nurse at the clinic assesses the needs and status of MT and his parents.

1. What is the patient's primary complaint?
2. What is concerning his parents?
3. What information must be included in the history and physical examination?
4. What education should the nurse prepare before the parents decide whether to start their son on androgen therapy?

   The decision is made to prescribe methyltestosterone (Striant) 30 mg twice daily by buccal tablet (held inside the cheek until it dissolves). MT will be on this regimen for 4 months, during which time he is to come to the clinic at monthly intervals.
5. MT asks why he will be treated for 4 months. What will the nurse reply?
6. About what adverse effects do MT and his parents need to be educated?
7. What physical and psychosocial parameters will be assessed at MT's monthly visits?
8. What special hygiene needs does MT have while on this regimen?
9. When should MT have x-rays taken? Explain your answer.
10. During a clinical visit, MT mentions that he heard that the use of anabolic steroids might improve his chances of making the wrestling team. What should he be told about the safety and efficacy of anabolic steroid use?

NCLEX STUDY QUESTIONS

1. A young male patient is referred to the nurse for initiation of intramuscular androgen therapy for hypogonadism. What information should the nurse give this patient? (Select all that apply.)
   a. A 4- to 6-month trial of androgen therapy will be followed by a period of rest for reevaluation.
   b. Sexual development will begin to occur immediately.
   c. Dosages may be adjusted based on periodic plasma testosterone levels.
   d. His growth will be monitored periodically by x-ray.
   e. The patient should not consume alcohol.
2. A married man with two daughters is taking finasteride (Proscar) to treat BPH. Which nursing assessment data are most critical in developing a care plan? (Select all that apply.)
   a. His spouse and children should not handle the drug.
   b. The drug may cause decreased libido and urinary retention.
   c. The dose needs to be reevaluated periodically.
   d. This drug may also cause his hair to grow.
   e. Using finasteride will not increase his risk for developing prostate cancer.
3. The nurse is discussing androgen therapy with a patient. Which statements will the nurse include in the patient education? (Select all that apply.)
   a. "Lower extremity edema associated with androgen therapy can be increased by corticosteroids."
   b. "Only men are prescribed androgen replacement therapy."

  c. “Androgen therapy is safe in pregnancy.”
  d. “Androgen therapy can affect your glucose levels, cholesterol, and thyroid and liver functioning.”
  e. “Androgen therapy may cause seizures.”

4. A man is taking androgen therapy for angioneurotic edema. He is complaining of nausea, increased urination, and loss of muscle tone. Which nursing advice has the highest priority?
  a. “Make an appointment to see the prescribing clinician within 5 to 7 days.”
  b. “Follow a clear liquid diet for 24 hours.”
  c. “Call 911 for immediate transport to the emergency department.”
  d. “Sign up for an exercise group at the local health club.”

5. During his annual physical examination, a patient tells the nurse he is in a new relationship and having some problems with erectile dysfunction. He is interested in nutrition and natural therapies. Which are the most appropriate responses by the nurse? (Select all that apply.)
  a. “Herbal therapies are commonly used by men to enhance sexual performance.”
  b. “Side effects from using some herbal therapies include increased anxiety, frequent headaches, and trouble sleeping.”
  c. “Phytochemicals have been widely researched and are safe to use.”
  d. “Men who have cardiovascular, neurologic, or psychological problems should not use some of the herbal products.”
  e. “It’s a good idea to increase your intake of dietary vitamins.”

6. The nurse is interviewing a man with erectile dysfunction who is interested in one of the phosphodiesterase inhibitors. Which response by the nurse is best for this patient?
  a. “The onset of action varies among the different drugs in this class.”
  b. “These medications should not be used if you take nitroglycerine for angina.”
  c. “Common side effects include headache, blurred vision, photosensitivity, changes in color perception, and urinary tract symptoms.”
  d. “There are many causes of sexual dysfunction in men, so a complete history and physical is the first step in treatment.”

7. A 17-year-old patient is brought to the health care provider by his father because he has been taking nutritional supplements sold at the gym. Which assessment data are most critical in developing a care plan for this patient? (Select all that apply.)
  a. His blood pressure is low.
  b. His acne is worsening.
  c. He has been in several fist fights with other teenagers.
  d. He has gained 60 pounds.
  e. His liver function tests are abnormal.

8. A patient with AIDS has been started on testosterone for tissue wasting and loss of muscle tone. Which report from the patient is the nurse’s highest priority concern?
  a. He reports that his muscle strength is about the same.
  b. He reports that he has morning erections lasting 30 minutes.
  c. He reports that he was out dancing last weekend.
  d. He reports that he has decided to become a vegetarian.

9. A male patient presents with complaints of lower urinary tract symptoms, getting up three times at night to urinate, dribbling after urination, and feeling pressure throughout the day. Recent screening laboratory tests are normal. The provider starts him on doxazosin (Cardura) 1 mg at bedtime. What advice can the nurse give this patient? (Select all that apply.)
  a. Advise the patient about signs and symptoms of low blood pressure.
  b. Tell the patient to notify his ophthalmologist about the doxazosin use before cataract surgery.
  c. Caution the patient that he should not allow his wife to handle the medicine.
  d. Advise the patient to immediately report problems of prolonged erection.
  e. Instruct the patient to take the medication on an empty stomach.

Answers: 1, a, c, d; 2, a, b, c, d; 3, a, d; 4, c; 5, a, b, d; 6, d; 7, b, c, d, e; 8, b; 9, a, b, d.

- Unfolding Case Studies

OBJECTIVES

- Explain the pathophysiology of conditions in women's health, pharmacologic therapies, and expected outcomes of pharmacologic therapies.
- Describe pharmacologic interventions targeting common pathogens causing vulvovaginal infections.
- Understand pharmacologic interventions used in the treatment of infertility in the male and female patient individually and as a couple attempting pregnancy.
- Describe the mechanism of action for ovulatory stimulation therapy.
- Identify drug therapies used for common gynecologic conditions such as dysfunctional uterine bleeding, endometriosis, dysmenorrhea, and premenstrual syndrome.
- Describe the pharmacologic intervention for sexually transmitted infections (STIs) caused by bacterial agents, viral agents, parasites, and other pathogens.
- Describe the nursing process, including teaching, related to drugs used in women's health, infertility, and the treatment of STIs.

dysmenorrhea, p. 888
endometriosis, p. 889
infertility, p. 893
menometrorrhagia, p. 887
menorrhagia, p. 887
metrorrhagia, p. 887
oligospermia, p. 898
pelvic inflammatory disease, p. 888
polycystic ovarian syndrome, p. 887
premenstrual syndrome, p. 890
sexually transmitted infections, p. 886
vaginitis, p. 891
vaginosis, p. 891
varicocele, p. 898

This chapter discusses the pathophysiology and typical drug regimens for disorders in women's health, including **sexually transmitted infections** (STIs). These gynecologic conditions interfere with a woman's overall health and well-being and may impede a woman's ability to become pregnant. Many of the medications discussed in Chapter 56 may also be used for relief of menstrual disorders and other gynecologic problems. Drugs for female and male infertility are also addressed, with an emphasis on medications that stimulate ovulation.

Sexually transmitted diseases are a threat to reproductive tract integrity and functioning, and to neonatal health. Not only do STIs affect the short-term and long-term health of a woman and her partner(s), they also are detrimental to the health of a community. Some STIs, such as human immunodeficiency virus (HIV), are life-threatening. Drug therapies that are recommended by the Centers for Disease Control and Prevention (CDC) for the treatment of specific STIs are reviewed.

MEDICATIONS USED TO TREAT DISORDERS IN WOMEN'S HEALTH

Common reasons women seek gynecologic health care include alterations in menstrual cycle, menstrual or pelvic pain, and changes in vaginal secretions. Included within these broad categories are irregular uterine bleeding, dysmenorrhea, premenstrual syndrome, and vulvovaginal infections. This section describes common disorders in women's health and presents current pharmacologic approaches to management.

Irregular or Abnormal Uterine Bleeding

Irregular uterine bleeding is a term that describes many different medical conditions or pathologies related to the menstrual cycle. Irregular uterine bleeding, also known as *abnormal uterine bleeding* (AUB), is a common reason women seek gynecologic care. AUB encompasses a wide range of variable bleeding patterns in women, such as amenorrhea, menorrhagia, metrorrhagia, menometrorrhagia, intramenstrual bleeding, and **dysfunctional uterine bleeding** (DUB).

Amenorrhea

Amenorrhea is the absence of menses. *Primary amenorrhea* is defined as no menses by age 14 years of age *without* secondary sex characteristics, or no menses by age 16 years *with* secondary sex characteristics. Primary amenorrhea may be caused by abnormalities in the structures of the female reproductive tract, chromosomal alterations, or endocrine disorders. Many times the cause is just a physiologic delay in the onset of menstruation. *Secondary amenorrhea* is the absence of a spontaneous menstrual period for 6 consecutive months in women who have experienced menstrual cycles in the past. Pregnancy is the most common reason a patient may experience amenorrhea, and breastfeeding or menopausal patients also may not menstruate; therefore, secondary amenorrhea is a *symptom* of these normal physiologic processes. Other causes of secondary amenorrhea include anovulatory cycles (cycles without ovulation), hypothyroidism or hyperthyroidism, and hyperprolactinemia (high levels of the hormone prolactin, which stimulates lactation). Extreme weight loss and anorexia can also cause amenorrhea.

After assessment of the patient's health history, a physical examination, and after pregnancy has been ruled out, a *progestational challenge test* may be administered to determine the underlying cause of amenorrhea. This test uses an oral progestin administered for a limited time to confirm that the hypothalamus-pituitary-ovarian (HPO) responses (the hormonal system mediating the menstrual cycle) are intact.

With the progestational challenge test, a patient is given either micronized progesterone (Prometrium) 400 mg by mouth (PO) at bedtime for 10 days or medroxyprogesterone acetate (Provera) 5 to 10 mg PO for 5 to 10 days. The progestational activity thickens the endometrial lining and increases secretory activity. When the medication is discontinued, progesterone levels decrease, resulting in a breakdown of the endometrial lining and withdrawal bleeding. Withdrawal bleeding should occur within 7 to 10 days after completing the medication and indicates that the HPO axis (the menstrual cycle) is functioning in providing the hormones necessary to regulate the menstrual cycle. Even the smallest amount of bleeding (one incidence of scant spotting) is considered a positive test. However, if there is no withdrawal bleeding, other pathophysiologic problems may exist and further evaluation and diagnostic testing by the health care provider are needed. Micronized progesterone contains peanut oil and thus is contraindicated in those with peanut allergies. The test can also be administered using a combined hormone contraception (CHC) product if the patient desires a form of contraception. The patient starts the CHC method as directed and should have withdrawal menses during the hormone-free phase.

Metabolic Syndrome

Another common cause of secondary amenorrhea is **polycystic ovarian syndrome** (PCOS). PCOS is a form of metabolic syndrome caused by the oversecretion of luteinizing hormone (LH). LH is the hormone responsible for stimulating ovulation, or mid-cycle release of an ovum from the dominant follicle in the ovary. Oversecretion of LH causes the formation of several follicular cysts in the ovaries instead of one dominant follicle. The presence of several follicles increases estrogen levels; however, ovulation does not occur. The cycle then becomes **anovulatory** (the absence of ovulation), and the luteal phase, or the second half of the menstrual cycle in which progesterone is dominant, is inhibited. The endometrium of the uterus is exposed to "unopposed" estrogen from the anovulatory cycles. *Unopposed estrogen* refers to levels of estrogen that are not balanced by a progestational (progesterone) effect. Unopposed estrogen can cause abnormal thickening of the endometrial lining, increasing the patient's risk for endometrial hyperplasia and uterine cancer. In women experiencing secondary amenorrhea, the incidence of PCOS may approach 30% as the cause of sequentially missed or irregular periods. These patients will complain of skipped menstrual cycles, long menstrual cycles (35 days or greater) or no menstruation for several months.

Insulin resistance is a hallmark of PCOS. Insulin resistance is the body's inability to respond to elevated glucose levels. Although insulin is secreted when glucose levels are high, "resistance" to the insulin results in altered glucose metabolism and hyperinsulinemia. Hyperinsulinemia causes higher levels of circulating androgens and predisposes the patient to alterations in lipid metabolism, cardiac disease, and type 2 diabetes mellitus. Women present with one or more of these symptoms: amenorrhea, hirsutism, acne, acanthosis nigricans (increased pigmentation and thickening of the skin, particularly in skinfold areas), or excessive fat along the midsection of the body. PCOS is a common cause of infertility because of the anovulatory cycles.

Pharmacologic treatment of PCOS depends on whether the patient desires pregnancy. If the patient wants to prevent pregnancy, estrogen-progestin combination contraception products are prescribed if the patient is a candidate. CHC products suppress LH and follicle-stimulating hormone (FSH) secretion, limit androgen symptoms, and regulate menstruation by providing a withdrawal bleeding period. With the addition of the progestin in the CHC product and a cycling of a monthly (or 4 times per year, depending on product) withdrawal menses, the risks of unopposed estrogen on the endometrium are significantly reduced.

For women who are attempting to conceive, two drugs, metformin and clomiphene citrate, are used. Metformin (Glucophage) inhibits the production of glucose in the liver and increases peripheral cell sensitivity to insulin, effectively treating insulin resistance and decreasing androgen levels. Metformin administration independently regulates the menstrual period and increases the possibility of ovulation. Metformin is initially prescribed as 500 mg, 1 tablet taken PO twice daily (b.i.d.), and may be increased to 850 mg b.i.d. Because metformin may decrease absorption of vitamin B_{12}, women should be assessed for vitamin B_{12} deficiency. Metformin also has gastrointestinal (GI) side effects (see Chapter 52).

Clomiphene citrate (Clomid or Serophene) is used in conjunction with metformin, or alone to promote a dominant follicle and induce ovulation; it is described in "Medications Used to Promote Fertility."

Abnormal Uterine Bleeding Patterns

The normal menstrual cycle occurs every 25 to 35 days and lasts 2 to 7 days, with an estimated blood loss of no more than 80 mL. **Menorrhagia** is *regular* uterine bleeding greater than 80 mL or lasting more than 7 days. Women with menorrhagia may describe their periods as very heavy or state the need to change a tampon or sanitary pad frequently. **Metrorrhagia** is *irregular* uterine bleeding greater than 80 mL or lasting more than 7 days. Women with menorrhagia describe their periods as irregular and heavy. They may state that they have no idea when bleeding will occur, and that when it does happen it will soak through sanitary products or clothing. **Menometrorrhagia** is a combination of these two. Intramenstrual bleeding is an episode of bleeding, usually light, that occurs between menstrual periods.

A common complaint that brings a woman into the gynecologic health care setting is that she is having menstrual cycles that are suddenly different from the pattern she usually experiences. In women of reproductive age, pregnancy should always be considered first as the possible cause of AUB. However, AUB can result from physiologic processes such as stress, severe dieting and weight loss, eating disorders, or excessive exercise. Irregular bleeding patterns are a sign of decreasing ovarian function or approach of menopause in older women. AUB can also be caused by pathologic processes such as endocrine disorders, thyroid disease, leiomyomata (benign tumors in the uterus), ovarian cysts, infections of the genital tract, or cancer. If a woman is pregnant, uterine bleeding may indicate ectopic pregnancy or impending miscarriage. Some pharmacologic medications, substances, and herbal preparations can also cause irregular bleeding, including anticoagulants, antipsychotics, benzodiazepines, hormone therapy, ginkgo, ginseng, and soy products. Once physiologic, pathologic, and pharmaceutic causes have been ruled out, the patient may be diagnosed with DUB.

Dysfunctional Uterine Bleeding

DUB is the most common classification of irregular bleeding. Diagnosis of DUB is made when no organic pathology can be determined to cause the irregular bleeding. Pharmacologic treatment of DUB primarily involves normalizing the bleeding pattern and correcting anemia that may have resulted from chronic or acute blood loss. In the normal physiologic menstrual cycle, estrogen and progesterone levels are low during menstruation. Once estrogen levels start to rise with the formation of a dominant follicle, uterine bleeding is effectively stopped, ending menstruation. Increasing levels of estrogen by administration of an extraneous estrogen drug product is usually effective in stopping prolonged DUB.

Since estrogen is never used alone in treatment (because of the detrimental effects of unopposed estrogen on the uterine endometrium and the risk for endometrial cancer), estrogen-progestin combination products are used. Progestins alone are not as effective as estrogen in reducing an episode of acute bleeding; however, because *prolonged* progestin administration causes atrophy of the endometrial lining, they can be very effective if long-term control is needed. Depot-medroxyprogesterone acetate (Depo-Provera) intramuscular (IM) injection or IUS/LNG (Mirena) inserted into the uterus are the products used for extended progestin therapy.

Pharmacologic Management of Irregular Bleeding

Nonsteroidal antiinflammatory drugs (NSAIDs) can be used for the treatment of menorrhagia. The mechanism of action for the management of uterine bleeding is not well understood. NSAIDs block the production of prostaglandin, which decreases both excessive bleeding and uterine cramps. Common NSAIDs used for menorrhagia are mefanamic acid (Ponstel), ibuprofen, and naproxen sodium. Only mefanamic acid has U.S. Food and Drug Administration (FDA) approval for menorrhagia. Ibuprofen and naproxen sodium are used by providers as an "off-label" option. The correct dosage of mefanamic acid is 500 mg PO once, followed by 250 mg PO every 6 hours for 2 to 3 days. Mefanamic acid should be taken with food.

CHC products can be used to decrease and regulate DUB. Monophasic products and products that have a dosage schedule of 21/7, 24/4, or 84/7 (see Chapter 56) are first-line drug therapy if the patient is a candidate for CHC products. The increase in estrogen stops uterine bleeding and maintains the endometrial lining. Withdrawal bleeding is cycled in to regulate periods of bleeding. If bleeding does not respond, the CHC can be increased to a schedule of 1 pill PO twice daily for 5 to 7 days, or until the bleeding stops, then 1 pill PO daily for 21 days. Reduction in flow should be seen within 24 hours. If a heavy flow continues for more than 48 hours, the patient should be reevaluated. Benefits, risks, and patient instructions are the same as if the product were being used for contraception. Women who are not a candidate for estrogen therapy or CHC products should excluded. Women using a CHC product for DUB should see their periods normalize within the first 3 months of use. The patient can continue the method for contraception or discontinue use in 6 to 9 months, depending on the effectiveness in controlling bleeding.

Progestins are not as effective as estrogens at reducing episodes of irregular bleeding. However, progestins are effective in the long-term treatment of AUB and may be the method of choice in women who have contraindications to estrogen use. Progestins can be given cyclically (e.g., norethindrone acetate 5 mg PO daily for 10 to 14 days) to produce a monthly withdrawal bleed, or in a continuous dose (e.g., medroxyprogesterone acetate 5 to 10 mg PO daily). Medroxyprogesterone acetate, norethindrone, and micronized progesterone are used in this manner. Depot-medroxyprogesterone acetate and the LNG-IUS are also be used for treatment of DUB. Long-term use of progesterone has an atrophic effect on the uterine endometrium, consequently decreasing incidences of irregular bleeding. Women using depot-medroxyprogesterone acetate or the LNG-IUS for DUB should see heavy bleeding patterns decrease within 3 to 6 months.

Dysmenorrhea

Dysmenorrhea is pelvic pain associated with the menstrual cycle. It is also called cyclic pelvic pain (CPP). Other symptoms that may occur are uterine cramping, lower back pain, abdominal cramps, changes in bowel patterns, increased bowel movements, and nausea and vomiting. Dysmenorrhea is experienced by approximately 80% of women in their late teens and early twenties, when it is more prevalent. It is the most common reason young women miss school or work. Dysmenorrhea is classified as either primary dysmenorrhea or secondary dysmenorrhea, depending on whether there is a known etiology for the menstrual pain. Primary dysmenorrhea is diagnosed when there is no apparent underlying pathology. It is caused by larger-than-normal amounts of prostaglandins at the start of the menstrual period. Prostaglandins cause arterioles in the uterus to contract, decreasing blood flow to the endometrium. All of these mechanisms are necessary for breakdown of the endometrial lining and for menstruation to occur. However, this process causes increased pain in some women.

In secondary dysmenorrhea, there is an underlying cause for the pelvic pain. Conditions that may cause secondary dysmenorrhea are urinary tract infections (UTIs), **pelvic inflammatory disease** (PID), irritable bowel syndrome (IBS), uterine leiomyomata (fibroids), and endometriosis.

Pharmacologic Management of Dysmenorrhea

Herbal, Botanical, and Vitamin/Mineral Therapy. The following vitamin therapy may provide pain relief in patients with mild dysmenorrhea: vitamin E (400 to 800 units/day), magnesium (dose ranges varied in clinical trials), thiamine (vitamin B_1, 100 mg/day), and zinc (1 to 3 mg/day a few days before menstruation). Omega-3 fatty acids (1 to 2 g/day) decreased the use of ibuprofen in women with dysmenorrhea in small clinical trials. Omega-3 fatty acids must be used with caution in individuals on anticoagulant therapy.

NSAIDs. NSAIDs block pain by preventing synthesis of prostaglandins. The mechanism of drug action is the inhibition of cyclooxygenase (COX). The COX enzyme converts arachidonic acid into prostaglandins, which cause constriction of the uterine arterioles, necrosis of the endometrial lining, uterine contractions, and menstrual pain. Usually nonselective and COX-2 inhibitors are used. The most commonly used NSAIDs for relief of pain associated with dysmenorrhea include naproxen sodium (Anaprox), diclofenac potassium (Cataflam), ibuprofen (Motrin), naproxen (Naprosyn), celecoxib (Celebrex), and mefenamic acid (Ponstel). Many NSAIDs can be purchased over the counter, so the nurse should include health information about the benefits, risks, and alternatives as well as specific dosage amounts, other drug interactions, and how to take the medication. Some (diclofenac potassium, celecoxib, and mefenamic acid) are by prescription only. Patients must understand the differences in these medications and avoid them if they have allergies to and/or side effects from any of the ingredients. They should avoid taking two different NSAID medications at the same time. GI upset is a common side effect of NSAIDs, so most drugs in this category should be taken with food and water. NSAIDs can also be taken with an antacid or calcium supplement to prevent GI upset. NSAIDs should not be taken for more than 10 days.

Hormonal Contraception. CHC products are effective in the treatment of dysmenorrhea. Extended-cycle CHC products such as 24/4 day products or 87/7 day products may be more effective. CHC products limit the thickness of the uterine endometrium. The 24/4 day CHC products shorten withdrawal bleeding periods, and the extended-cycle CHC products decrease the number of withdrawal menses per year or eliminate them altogether. Depo-Provera, Implanon, and the LNG-IUS decrease dysmenorrhea in patients who are candidates for these methods. Long-term progestin-only products cause atrophy of the uterine lining, limiting the occurrence of dysmenorrhea and the amount of bleeding during menstruation.

Endometriosis

Endometriosis is the abnormal location of endometrial tissue outside the uterus. The tissue is known as *ectopic endometrial implants*. It is a common cause of dysmenorrhea, chronic pelvic pain, and infertility. The ectopic endometrial implants can be found affixed to the ovaries, the posterior surface of the uterus, the uterosacral ligaments, the broad ligaments, or the bowel. They also can be found on other organs within the pelvic or thoracic cavity. The ectopic endometrial implants respond to hormonal control, particularly estrogen, in the same way as the normal endometrial tissue located inside the uterus. Thus, when menstruation occurs, the ectopic endometrial implants proliferate and then bleed. As the number of menstrual cycles increases, inflammation of surrounding organ tissue, scar tissue formation, and adhesions result, causing pelvic pain.

Diagnosis of endometriosis is based on laparoscopic evidence of endometrial tissue, or implants, outside the uterus. The most common symptoms of endometriosis are dysmenorrhea and pelvic pain, sometimes including chronic pelvic pain, which lasts more than 6 months and is not associated specifically with menstruation. The patient may experience back pain; painful, sometimes bloody, bowel movements; and dyspareunia (painful sexual intercourse). An increased number of women with endometriosis experience primary or secondary infertility; although a specific cause linking the two has not been established. It is theorized that the ectopic endometrial implants, or the resultant scar tissue and adhesions, obstruct or affect the motility of the fallopian tubes or other reproductive organs. Affected women have an increased risk for ectopic pregnancy.

Pharmacologic Management of Endometriosis

Pharmaceutic treatment strategies for endometriosis include drugs that decrease the amounts of circulating estrogen and limit or eliminate menstruation. This interrupts internal bleeding and irritation associated with the ectopic endometrial implants and may even cause them to recede.

CHC Products. These drugs suppress gonadotropin-releasing hormone (Gn-RH) release, prevent ovulation, and cause atrophy of the uterine lining, actions thought to relieve pelvic pain by causing a regression of the endometrial implants. CHCs relieve the pain of endometriosis in approximately 75% of women. Extended-cycle CHC products can also manage endometriosis by causing fewer cycles per year or eliminating withdrawal menses altogether.

Progestational Products. These drugs suppress ovulation and cause long-term endometrial atrophy. They also inhibit Gn-RH release, similar to CHCs. Over time, progestins can shrink or eliminate endometrial implants. The most commonly used progestin is depot-medroxyprogesterone acetate (DMPA) in the form of Depo-Provera and Depo-subQ 104 Provera. With DMPA, 70% to 90% of patients experience relief of symptoms associated with endometriosis. This effect may last months after discontinuing the medication. Benefits and risks are the same as if using DMPA for contraception, so concerns for bone mineral density (BMD) loss and prevention, irregular bleeding or amenorrhea, possible weight gain, and mood changes should be discussed with the patient (see Chapter 56). The injection is given every 11 to 13 weeks.

A progestin that can be taken in an oral form is norethindrone acetate (Aygestin), 5 mg PO daily for 2 weeks, then increasing the dose by 2.5 mg every 2 weeks until a dose of 15 mg per day is reached. This is continued for 6 to 9 months.

Gn-RH Agonists. Gn-RH agonists are potent drugs that inhibit Gn-RH release and create a hypoestrogenic environment. The side effects are also menopause-like, with hot flashes, atrophic vaginitis, vaginal dryness, decreased sex drive, and potential for bone loss. Leuprolide (Lupron Depot 3.75 mg) is given in a 3.75-mg dose IM monthly for up to 6 months. Leuprolide is also available in a 3-month dosage schedule (Lupron Depot-3 Month 11.25 mg) given via IM injection once every 3 months for up to 6 months. Leuprolide should be initiated in the first 3 days of the menstrual cycle as it is pregnancy category X. Women may be able to become pregnant on leuprolide, so a barrier method of contraception should be used. Progestins or CHC products can also be prescribed to prevent pregnancy and reduce bone loss.

Nafarelin (Synarel Nasal Spray) is administered in a 400-mcg/day dose; with 1 spray (200 mcg) into one nostril in morning and 1 spray (200 mcg) into the other nostril in evening for up to 6 months. Goserelin (Zoladex) is administered in a 3.6-mg dose in a subcutaneous implant placed in the abdominal wall every 28 days for 6 months. The Gn-RH agonists should be used for only 6 months. Use of these medications past 6 months, as well as retreatment, can cause irreversible adverse changes in BMD. Approximately 90% of women experience relief of symptoms with gonadotropin inhibitors and Gn-RH agonists.

Studies investigating DMPA preparations compared with Gn-RH inhibitors/agonists report that Depo-SubQ 104 Provera is as effective as leuprolide in reducing symptoms of endometriosis and shrinking or eliminating endometrial implants. DMPA preparations are much less expensive for the patient than leuprolide. Leuprolide causes a higher hypoestrogen state than DMPA; therefore, menopause-like symptoms are much more severe. DMPA, in studies, caused irregular bleeding including menorrhagia, weight gain, and prolonged time returning to menstruation after the treatment was discontinued. DMPA also causes BMD changes, and preventive measures must be reviewed with the patient before initiating treatment.

Aromatase inhibitors (nastrozole, letrozole) suppress the conversion of androgens into estrogens and are prescribed for up to 6 months.

Premenstrual Syndrome

Premenstrual syndrome (PMS) comprises a collection of cyclic physical symptoms and perimenopausal mood alterations. Symptoms increase in the 2 weeks before menstruation and subside after menses begins. These physical, emotional, and behavioral symptoms interfere to varying degrees with a woman's ability to function. PMS falls under the classification of cyclic perimenstrual pain and discomfort.

PMS can result in decreased work effectiveness and distressing mood variations. PMS affects 40% of all adult women, with about 5% exhibiting debilitating symptoms. These debilitating symptoms may be classified as premenstrual dysphoric disorder (PMDD) if severe mood swings are exhibited. PMDD is recognized by the American Psychiatric Association as a "depressive disorder not otherwise specified." The hallmark of PMS and PMDD is that symptoms occur in a repetitive pattern during the luteal phase (days 15 to 28) of the menstrual cycle and decrease significantly in the early follicular phase (days 1 to 14).

There is no universal agreement about the definition, etiology, symptoms, or treatment of PMS. Researchers theorize that the etiology of PMS could be hormonal excess or deficits, fluid or sodium retention, or nutritional deficiencies. It is also proposed that an imbalance in the HPO axis function exists. Other hypotheses center on the neuroregulatory effects of estrogen and progesterone on the release or uptake of serotonin.

A patient can help with the diagnosis of PMS by recording three variables on a perimenstrual assessment calendar: (1) group of symptoms (Box 58-1), (2) severity of symptoms, and (3) impact on function (degree of distress). Diagnosis of PMS can be made when the patient's symptoms consistently occur in a cyclic pattern at least 1 week before the menstruation cycle and decrease significantly after menses begins. Symptoms usually have a negative impact on the ability to function effectively. Other endocrine abnormalities must be ruled out. Also, it should be noted that not every symptom associated with the menstrual cycle is indicative of PMS.

BOX 58-1 GROUPING OF SYMPTOMS OF PREMENSTRUAL SYNDROME

Physical

Weight gain
Edema
Bloating in lower abdomen
Breast soreness
Fatigue
Backaches
Acne flare-ups
Joint pain
Constipation
Headache
Insomnias, alterations in sleep patterns, lack of healthy sleep hours

Emotional

Anger
Anxiety
Agitation
Feelings of being out of control
Labile emotions and rapid mood alterations
Tension
Difficulty with concentration
Irritability
Tearfulness
Depression
Suicidal thoughts

Behavioral

Increased or decreased sexual desire
Impulsive behavior
Increased appetite
Acting out aggression or emotional alterations
Cravings for foods high in sugar or salt
Sudden increase or decrease in activity

Pharmacologic and Complementary and Alternative Treatment of PMS

Pharmacologic treatment of PMS should consider evidence-based recommendations that are appropriate in treating the patient's specific symptoms. The following treatments have been identified.

Nonpharmacologic Treatment. Nonpharmacologic treatment modalities are very important in treating women with PMS. They include expression of empathy, support from family and friends, correction of knowledge deficits about PMS, exercise, and dietary changes. Aerobic exercise improves general health, heightens endorphin levels, and may facilitate an overall sense of well-being. Dietary changes include limiting salty foods, alcohol, caffeine, and concentrated sweets. Eating four to six small, high-carbohydrate, low-fat meals may also help relieve some symptoms. Stress-reduction exercises are also helpful. These measures may help the patient feel proactive regarding her diagnosis of PMS.

Herbal, Botanical, and Vitamin/Mineral Therapy. Some patients experience improvement with selected symptoms through use of vitamin B_6 (pyridoxine), which is popular but not found superior to placebo. Increased calcium intake through diet, not via supplementation, has also been suggested for symptom relief of PMS. Studies indicate that calcium has an inverse relationship with PMS: the higher the intake of calcium, the lower the PMS risk. Since calcium and B_6 are relatively benign when taken in the recommended allowances, both can be used by women to treat PMS symptoms.

Studies on evening primrose oil have had mixed results, although supporters say that it lessens premenstrual mood alterations, helps alleviate breast tenderness, and decreases fluid retention. Chasteberry may help with some PMS symptoms as well as breast pain. Chasteberry prevents progesterone overproduction and inhibits prolactin release (prolactin may be elevated in women with breast tenderness).

St. John's wort has demonstrated efficacy for mild depression that may accompany PMS and PMDD. The mechanism of action is unclear. St. John's wort should not be used if the patient is taking monoamine oxidase inhibiters or has been prescribed selective serotonin reuptake inhibitors (SSRIs). Many herbal or botanical supplements have variations in active ingredient dosing and purity because they may not be approved by the FDA for a specific use.

Antidepressant and Antianxiety Medications. Severe PMS is improved with SSRIs or SSRI medications. The American College of Obstetricians and Gynecologists suggests that SSRIs be taken either continuously or cyclically on days 15 to 28 of the menstrual cycle. Symptom relief includes a decrease in irritability, mood swings, fatigue, tension, and breast tenderness. SSRIs block the reuptake of serotonin into nerve terminals in the CNS, regulating serotonin use by the brain. The most commonly used SSRIs are fluoxetine hydrochloride (Prozac) and sertraline hydrochloride (Zoloft), although paroxetine hydrochloride (Paxil) and citalopram (Celexa) have also demonstrated relief in patients with severe PMS symptoms. Fluoxetine has been repackaged and remarketed to women as Sarafem.

For the management of severe PMS or PMDD, antianxiety medications may be prescribed to reduce or eliminate anxiety and control panic disorders. Antianxiety medications may also help with depression and headaches associated with PMS. The most commonly used medications include alprazolam (Xanax), diazepam (Valium), lorazepam (Ativan), and buspirone (BuSpar). These medications should be used in the short term because of their potential for tolerance or addiction. Patients should be warned that they also may cause sedation. Antianxiety medications are not recommended as first-line of treatment for severe PMS. Treatment for longer than 8 weeks warrants continued medical or psychiatric surveillance.

Hormonal Therapy. Long-term suppression of ovulation has been shown to decrease cyclic physical discomforts and normalize mood variations in some women. Monophasic CHC products such as oral contraception pills, Ortho-Evra, and Nuva Ring can be used in this manner. Caution should be used with progestin-only products because they may exacerbate symptoms of depression. Oral contraceptives such as Yaz, Beyaz, and Lybrel are approved by the FDA for treatment of PMDD.

Common Vulvovaginal Infections

Another common reason women seek out gynecologic care is changes in vaginal secretions or vulvar and vaginal pruritus, irritation, or pain. Vaginal secretions are normal, may change throughout a women's menstrual cycle, lubricate the vaginal and external genitalia, and maintain a healthy vaginal microecosystem. Normal vaginal secretions are clear to white, may be slightly slippery or sticky, and have a mild odor; the secretions may turn yellow on underwear or panty liners. Three vaginal infections change normal vaginal secretions into abnormal vaginal discharge and cause different vulvar or vaginal symptoms: vulvovaginal candidiasis (VVC), bacterial **vaginosis** (BV), and trichomoniasis. **Vaginitis** is the term used to describe inflammation in the vaginal area.

Vulvovaginal Candidiasis. VVC is a yeast infection of the vulva or vaginal area. It causes inflammation, irritation, pruritus, excoriations, and burning on urination or intercourse, and it usually presents with a thick, white, curdlike discharge. The causative agent is most often an overgrowth of *Candida albicans,* normal flora in the vagina; other *Candida* species can also cause VVC. Uncomplicated VVC is treated with topical drugs from the azole category. There are 1-day antifungal agents, as well as 3- and 7-day vaginal treatments. Some antifungal medications can be purchased over the counter; others need a prescription. Table 58-1 lists common medications used to treat VVC.

Bacterial Vaginosis. BV causes larger amounts of homogenous, thin, white vaginal discharge with a strong fishy odor. Normal, healthy bacteria in the vagina—lactobacilli—are replaced with anaerobic bacteria, most commonly *Gardnerella vaginalis* or *Mobiluncus.* BV can be transmitted via sexual contact but is not considered an STI. BV is treated with metronidazole (Flagyl) 250 mg PO three times a day for 7 days, 500 mg PO twice a day for 7 days, or 750 mg extended-release tablet (Flagyl ER) once daily for 7 days. Metronidazole can also be taken in a one-time 2-g dose by taking four 500-mg tablets PO. Since metronidazole can cause stomach upset, it should be taken with food or a full glass of water or milk. Alcohol causes severe nausea and vomiting when ingested with metronidazole, so the patient should be instructed not to drink alcoholic beverages or use products that contain alcohol (such as mouthwash) for the duration of drug therapy and for 48 hours after treatment. These vaginal preparations are also effective in treating BV: metronidazole gel 0.75%, one full applicator intravaginally at bedtime for 5 nights; or clindamycin cream 2%, one full applicator intravaginally at bedtime for 5 days.

Tinidazole (Tindamax) is also used to treat BV. It is prescribed in two 500-mg tablets that are taken in 1 dose PO for 5 days or four 500-mg tablets taken in 1 dose daily PO for 2 consecutive days. Tinidazole has the same precautions with alcohol as metronidazole and should be taken with food. Tinidazole causes slightly less GI upset than metronidazole.

TABLE 58-1 COMMON VAGINAL INFECTIONS AND PHARMACOLOGIC TREATMENT

INFECTION	CDC-RECOMMENDED REGIMENS	NOTES
Vulvovaginal Candidiasis		
Recurrent vulvovaginal candidiasis may be indicative of other disease, such as diabetes or HIV infection.		
Vaginal Preparations with Butoconazole		
Femstat-3 (OTC)	Butoconazole 2% cream 5 g intravag for 3 d or	Pregnancy category: C Number following brand name indicates number of days product is to be used.
Gynezole-1 (Rx only)	Butoconazole 2% cream 5 g (Butaconazole-1) single intravag application	All suppositories and creams listed are inserted intravaginally.
Vaginal Preparations with Clotrimazole		
Gyne-Lotrimin 7 Cream (OTC)	Clotrimazole 1% cream 5 g intravag for 7-14 d or	Pregnancy category: B
Gyne-Lotrimin 7 Combination Pack (OTC)	Clotrimazole 100-mg vag tab for 7 d or	
Gyne-Lotrimin 3 Cream (OTC)	Clotrimazole 100-mg vag tab, 2 tab for 3 d	
Vaginal Preparations with Miconazole		
Monistat-7 Cream (OTC)	Miconazole 2% cream 5 g intravag for 7 d or	Monistat comes in a variety of products, cream only, vaginal suppository only, and combination packs with both vaginal suppositories and cream.
Monistat-7 Suppositories (OTC)	Miconazole 100-mg vag supp, 1 supp for 7 d or	Pregnancy category: C; use is not recommended in first trimester.
Monistat-3 Suppositories (OTC)	Miconazole 200-mg vag supp, 1 supp for 3 d or	Number following brand name indicates number of days product is to be used.
Monistat-1 Combination Pack (OTC)	Miconazole 1,200-mg vag supp, 1 supp for 1 d	
Vaginal Preparations with Nystatin		
Nystatin (Rx only)	Nystatin 100,000-unit vag tab, 1 tab for 14 d	Pregnancy category: A
Vaginal Preparations with Terconazole		
Terazol 7 Cream (Rx only)	Terconazole 0.4% cream 5 g intravag for 7 d or	Pregnancy category: C
Terazol 3 Cream	Terconazole 0.8% cream 5 g intravag for 3 d or	
Terazol 3 Suppositories	Terconazole 80-mg vag supp, 1 supp for 3 d	
Vaginal Preparations with Tioconazole		
1-Day (OTC)	Tioconazole 6.5% ointment 1 applicatorful in a single dose	Pregnancy category: C
Vagistat-1 Ointment (OTC)	Tioconazole 6.5% ointment 1 applicatorful in a single dose	Complete relief may take up to 7 days.
Oral Preparations		
Diflucan (Rx only)	Fluconazole 150-mg oral tablet, one tab PO in a single dose	Pregnancy category: D
Bacterial Vaginosis		
Clindamycin		
Cleocin Vaginal Cream (Rx only)	Clindamycin cream 2% 1 full applicator (5 g) intravag h.s. for 3-7 d or	Pregnancy category: B
Cleocin Vaginal Ovules (Rx only)	Clindamycin ovules 100 mg intravag h.s. for 3 d or	
Clindesse (Rx only)	Clindamycin cream 2% 1 full applicator intravag in a single dose or	
Oral Clindamycin	Clindamycin 300 mg PO b.i.d. for 7 d	

TABLE 58-1 COMMON VAGINAL INFECTIONS AND PHARMACOLOGIC TREATMENT—cont'd

INFECTION	CDC-RECOMMENDED REGIMENS	NOTES
Metronidazole		
Flagyl ER Oral Tablets (Rx only)	Metronidazole 750-mg tab PO for 7 d or	Pregnancy category: B All ETOH products should be avoided when taking oral metronidazole during treatment and for 3 days after use. Should be taken with food. Oral metronidazole should not be used in first trimester of pregnancy. Second and third trimester: Pregnancy category: B
Flagyl (Rx only)	Metronidazole 500 mg PO b.i.d. for 7 d or	
Flagyl (Rx only)	Metronidazole 2 g PO in a single dose or	
MetroGel Vaginal (Rx only) or Vandazole (Rx only)	Metronidazole vaginal 0.75% gel 1 full applicator 1-2 times/d for 5 d	
Tinidazole		
Tindamax (Rx only)	250-mg or 500-mg tabs 2 grams daily PO for 2 d or 1 gram daily PO for 5 d Tinidazole 2 g/d for 2 d or 1 g/d for 5 d	When taking oral tinidazole, avoid all ETOH products during treatment and for 3 days after use. Take with food. Do not use oral tinidazole in the first trimester of pregnancy. Second and third trimester: Pregnancy category: B Fewer GI side effects than metronidazole

b.i.d., Twice a day; *d,* day; *ER,* extended-release; *g,* gram; *GI,* gastrointestinal; *h.s.,* at bedtime; *intravag,* intravaginally; *mg,* milligram; *OTC,* over-the-counter; *PO,* by mouth; *q,* every; *Rx,* prescription; *supp,* suppository; *tab,* tablet; *vag,* vaginally.

Both medications should not be taken in the first trimester of pregnancy.

Trichomoniasis. Trichomoniasis is sometimes grouped with other vulvovaginal infections because of the changes *T. vaginalis* causes in vaginal secretions and associated vaginal irritation. However, trichomoniasis is an STI and is discussed in the section on STIs later in this chapter.

MEDICATIONS USED TO PROMOTE FERTILITY

Infertility is defined as the inability to conceive a child after 12 months of unprotected sexual intercourse. Women older than 35 years may be considered infertile after 6 months of attempting pregnancy. Infertility is considered primary infertility if a couple has never conceived or has never carried a pregnancy to term. Secondary infertility describes a couple who has conceived and brought a pregnancy to term but is unable to conceive afterward. Approximately 15% to 20% of couples in the United States experience infertility. Fertility rates decrease in both men and women as they get older; however, the risk for infertility increases more abruptly in women than in men as women reach the end of the reproductive life cycle. The monthly chance of achieving pregnancy decreases to 5% after age 40 years.

Assessing the Infertile Couple

Causes of infertility are numerous (Table 58-2). Infertility can be attributed to a female factor, a male factor, and many times, a combination of both. In the female partner, the most common causes for infertility are alterations in ovarian function and anatomic disorders. Alterations in ovarian function are categorized as *ovulatory dysfunction disorders*. Any process, whether a disease state or the normal biologic process of aging, that causes anovulation (lack of ovulation) or a decrease in ovulation cycles will affect the process of conception. Many of these women present with irregular menstrual periods. Causes of ovulatory dysfunction include alterations in the HPO axis, such as metabolic disorders (most commonly PCOS), and age approaching the end of the reproductive spectrum. Fertility declines sharply in women after age 35 years, and infertility becomes a factor from age 38 to 40 years. Endocrine disorders such as hyperprolactinemia (increase in circulating prolactin, the hormone that promotes breastfeeding) or thyroid disorders (hypothyroidism or hyperthyroidism) also can cause anovulatory cycles. Ovulation can be disrupted by eating disorders (anorexia and bulimia) and by stress.

The most common anatomic disorder is blocked fallopian tubes. Blocked tubes can be the result of a history of STI or PID. STIs, treated or undiagnosed, and PID can lead to scarring within the tubes, impeding sperm or ovum transport. A previous ectopic pregnancy or other tubal surgery can also result in infertility. Other causes include endometriosis, uterine leiomyomata (fibroids), or scarring within the uterine endometrium.

Male causes of infertility include any disease process that prevents sperm production or blocks sperm transport. Undescended testicles, surgical removal of the testes, STIs or other

TABLE 58-2 CAUSES OF INFERTILITY

Female Factors	
Genetic	Chromosomal abnormalities, enzyme defects
Tubal or peritoneal	Infection, occlusion, fimbriae damage, pelvic adhesions, endometriosis
Ovarian	Anovulation, oligoovulation, inadequate luteal phase, polycystic ovarian syndrome (PCOS)
Cervical	Cervicitis, poor-quality cervical mucus, diethylstilbestrol exposure (daughter and granddaughter of DES exposure)
Uterine	Uterine fibromas, congenital malformations, adhesions, endometrial abnormalities
Endocrine	Panhypopituitarism, hypothyroidism, adrenal insufficiency, congenital adrenal hyperplasia, Cushing's disease, cirrhosis, hyperprolactinemia, hormone receptor defects
Other	Age, drugs, malnutrition, excess alcohol intake, tobacco use
Male Factors	
Genetic	Chromosomal genetic abnormalities
Seminal	Failure of semen to liquefy, inadequate volume, low sperm count, decreased or erratic sperm motility, sperm dysmorphology, varicocele
Transport	Hypospadias, micropenis, retrograde ejaculation, epididymitis, impotence, ductal occlusion, ductal adhesions
Testicular	Oligospermia/azoospermia, cryptorchidism, testicular agenesis, history of high fever, postpubertal orchitis, testicular injury/surgery, varicocele
Endocrine	Panhypopituitarism, hypothyroidism, adrenal insufficiency, congenital adrenal hyperplasia, Cushing's disease, cirrhosis, hormone receptor abnormalities
Other	Age, drugs, excess alcohol intake, tobacco use, pollution, malnutrition, scrotal heat exposure, autoimmunity to sperm, infectious processes, allergies
Couple Factors	Sexual technique, frequency or timing of intercourse, immune response to sperm

infections of the internal genitalia, hypospadias, environmental factors, and sexual dysfunction can also contribute to infertility. Some medications affect sperm quality and migration.

Treatment of infertility depends on the cause. General health assessment of the infertile couple includes (1) complete health history, including nutritional, reproductive, and social histories; medications; herbal and illicit drug use; and gynecologic, menstrual, obstetric, and sexual histories as they pertain to each partner; (2) complete physical examinations with breast and pelvic examinations of the female partner and examination of male genitalia and function; (3) Pap testing, HPV testing, collections of cultures for STI testing; and (4) laboratory tests and other diagnostic tests. Semen evaluation is also necessary. Common tests to determine the specific causes of infertility are listed in Table 58-3.

TABLE 58-3 COMMON TESTS FOR INFERTILITY

TEST	PURPOSE
Physical examination	Assess secondary sex characteristics, reproductive tract function, and patency by gross examination Assess for hyperandrogen symptoms
Hematology, liver and renal function	Rule out disease processes
Hysterosalpingogram, tubal insufflation	Evaluate fallopian tube patency
Cervical mucus test	Assess viscosity of mucus and its effect on sperm motility
Plasma progesterone	Assess function of corpus luteum
Endometrial biopsy	Assess ovulatory status or adequacy of corpus luteum
Semen analysis	Check number, structure, movement of sperm
Basal body temperature	Determine whether ovulation occurs; document temperatures daily in chart
Sperm penetration assay	Determine ability of sperm to penetrate and fertilize ovum
Laparoscopy	Visualize female pelvic organs
Hysteroscopy	Visualize uterus
Echohysteroscopy	Assess structure of woman's internal reproductive organs
Hormone assays	Assess Gn-RH, FSH, LH, progesterone, estrogen, prolactin, testosterone, and thyroid hormone levels
Immunologic testing	Assess cervical immunity against sperm, seminal fluid immunity against sperm, and serum antisperm antibodies in either partner
Imaging	Pituitary integrity

FSH, Follicle-stimulating hormone; *Gn-RH,* gonadotropin-releasing hormone; *LH,* luteinizing hormone.

One of the leading causes of infertility in women is ovulatory dysfunction disorders, usually in the form of PCOS or other metabolic syndromes. The first line of pharmacologic treatment for ovulatory dysfunction disorders is usually induction of ovulation by oral drug therapy.

Induction of Ovulation

Clomiphene citrate (CC) is an estrogen antagonist that binds with estrogen receptors within the hypothalamus. By binding to the estrogen receptors, the hypothalamus is led to believe that circulating estrogen levels are low. This sets the hypothalamus in motion to secrete more Gn-RH, stimulating the HPO axis. The Gn-RH instructs the anterior pituitary gland to release FSH and LH to initiate a response from the ovarian follicles. Estrogen levels increase in response to FSH and LH,

PROTOTYPE DRUG CHART 58-1

Clomiphene Citrate

Drug Class

Ovulation stimulant
Trade Names: Clomid, Serophene
Pregnancy Category: X

Dosage

A: PO: 50-150 mg/d for days 5-9 of cycle
If ovulation does not occur with 50 mg/d, increase next course to 100 mg/d.
Maximum dose is 150 mg/d; maximum sequential cycles is three.
Under strict supervision by physicians specializing in infertility, as much as 250 mg/d may be used.

Contraindications

Pregnancy, undiagnosed vaginal bleeding, depression, fibroids, hepatic dysfunction, thrombophlebitis, primary pituitary or ovarian failure

Drug-Lab-Food Interactions

Drug: None are significant; danazol may inhibit response; decrease effects of ethinyl estradiol
Lab: Increase in serum thyroxine

Pharmacokinetics

Absorption: Readily absorbed from GI tract
Distribution: PB: UK
Metabolism: t½: 5-8 d
Excretion: In feces

Pharmacodynamics

PO: Onset: 5-14 d
Peak: UK
Duration: UK

Therapeutic Effects/Uses

To stimulate ovarian follicle growth
Mode of Action: Stimulates release of follicle-stimulating hormone and luteinizing hormone

Side Effects

Breast discomfort, fatigue, dizziness, depression, anxiety, nausea, vomiting, constipation, increased appetite, headache, flatulence, multiple gestation, hot flashes, fluid retention

Adverse Reactions

Visual disturbances, abdominal pain, weight gain, hair loss, ovarian hyperstimulation, anxiety, ovarian cysts, ectopic pregnancy

A, Adult; *d,* day; *GI,* gastrointestinal; *PB,* protein-binding; *PO,* by mouth; *t ½,* half-life; *UK,* unknown.

and a follicle becomes dominant, producing the level of estrogen needed for the LH surge. The LH surge causes ovulation of an ovum from the dominant follicle. It is important that LH reach a level high enough to produce an ovulatory cycle and that the timing of the LH surge be at the height of follicle formation, which is mid-cycle.

CC is the most commonly used ovulation stimulant (Prototype Drug Chart 58-1). Women with PCOS may need concurrent treatment for hyperinsulinemia with metformin. Metformin alone will help regulate the menstrual cycle and promote ovulation; however, when it is paired with CC, the success rate is increased.

CC is given in a 50-mg oral dose on days 5 through 9 of the menstrual cycle. If ovulation does not occur, the dose can be increased by 50-mg increments to 100 mg, then 150 mg, up to 250 mg orally on days 5 through 9, in sequential cycles, until ovulation is achieved. Usually, no more than three cycles of CC are used. Women are at an increased risk for multiple gestation; usually no more than a twin gestation is experienced.

Recombinant FSH, LH, and human chorionic gonadotropin (hCG) promote normal hormone levels with minimal adverse effects (Table 58-4). Recombinant FSH (Bravelle, Follistim, Gonal F) and recombinant LH (Luveris) work directly on ovarian function to stimulate follicle maturation and promote ovulation. These therapies supply women with exogenous hormones to enhance the normal physiologic process of the menstrual cycle, promoting ovulation and increasing the probability of conception. HCG (A.P.L., Pregnil, Novarel, Ovidrel) ensures development of the corpus luteum *after* ovulation. The corpus luteum provides for adequate levels of both estrogen and, more importantly, progesterone, to maintain the uterine endometrium and a pregnancy, should one occur. These drugs are more potent than CC and have an increased risk for multiple births. HCG further enhances ovulation in women who have been pretreated with gonadotropins, FSH, or LH.

Pharmacokinetics Data on the pharmacokinetics of CC are limited, but clomiphene is readily absorbed from the GI tract. It is partially metabolized in the liver and excreted in the feces via biliary elimination. CC has a half-life of about 5 days.

Pharmacodynamics The mechanism of action of CC is unknown, but it is hypothesized that it competes with estrogen at receptor sites. The perception of decreased circulating estrogen by the hypothalamus and pituitary gland triggers the negative feedback response that increases secretion of FSH and LH. The results are ovarian stimulation, maturation of the ovarian follicle, ovulation, and development of the corpus luteum.

Side Effects. Side effects of CC include breast discomfort, fatigue, dizziness, depression, nausea, increased appetite, dermatitis, urticaria, anxiety, weakness, heavier menses, vasomotor flushing, and abdominal bloating or pain. Antiestrogenic effects include interference with endometrial maturation and cervical mucus production. Paradoxically, this may interfere with fertilization or implantation.

TABLE 58-4 OVULATORY STIMULANTS AND OVULATION CONTROL

GENERIC (BRAND)	ROUTE AND DOSAGE	USE AND CONSIDERATIONS
bromocriptine mesylate (Parlodel)	1.25-2.5 mg/d; may increase by 2.5 mg every 2-7 d; *max:* 2.5-15 mg/d	Normalizes prolactin levels. Possibly teratogenic. Pregnancy category: C; PB: 92%; t½: 50 h
clomiphene citrate (Clomid, Serophene)	See Prototype Drug Chart 58-1.	
Gn-RH analogues Agonists: Synarel Antagonists: Cetrotide, Ganirelix	Synarel: Spray up to 800 mcg/d (200 mcg per nostril b.i.d.) Cetrotide: 0.25 mg in a single dose subQ daily on stimulation day 5 or day 7, or 3 mg subQ in a single dose on stimulation day 7 (to control day of LH surge) Ganirelix: 250 mcg subQ once daily after initiating FSH, during mid to late follicular stage.	Enhances ovulation stimulation for IVF cycles by suppression of a spontaneous LH surge. (Controls fertility cycle, improving pregnancy outcomes.) PB: UK; t½: 11-23 h
human menotropic gonadotropins (Humegon, Pergonal, Serono, Repronex)	IM injection: Humegon, Pergonal, Serono subQ: Repronex Dosage determined by patient 75 : 75 units of FSH : LH or 150 : 150 units of FSH : LH once daily for 5 or more days	Possesses same activities as FSH and LH therefore will induce ovulation in women with hypothalamic amenorrhea. Ovarian hyperstimulation is a risk. Multiple gestation is a risk. Pregnancy category: X
recombinant FSH (Gonal-F, Follistim) human menopausal gonadotropin or hMG (similar to FSH) (Repronex, Menopur)	Recombinant FSH: subQ or IM injection; dosage individualized for each patient, usually 75-150 units daily, early follicular phase continuing for 10-14 d Recombinant LH: subQ 75 units given subQ along with an FSH or recombinant FSH	Recombinant FSH possesses same hormonal activities as FSH. Ovarian hyperstimulation remains a risk, though minimal, with recombinant products. Multiple gestation is a risk, which is reduced by careful monitoring. PB: UK; t½: 23-77 h IM, 13-35 h subQ
recombinant LH (Luveris, Novarel, A.P.L., Pregnyl); recombinant human chorionic gonadotropin or hCG (Ovidrel)	Recombinant hCG 250 mcg prefilled syringe subQ injection given 1 d after last dose of gonadotropin (FSH and/or LH) 5000-10,000 units IM 1 d after last dose of gonadotropin (FSH and/or LH)	Pregnancy category: X Avoid herbal supplements containing black or blue cohosh

d, Day; *FSH,* follicle-stimulating hormone; *Gn-RH,* gonadotropin-releasing hormone; *h,* hour; *hCG,* human chorionic gonadotropin; *IM,* intramuscular; *LH,* luteinizing hormone; *min,* minute; *PB,* protein-binding; *subQ,* subcutaneously; *t½,* half-life; *UK,* unknown.

Adverse Reactions. Adverse reactions include photophobia, mastalgia, diplopia, and decreased visual acuity. Ovarian hyperstimulation may result in ovarian enlargement, midcycle ovarian pain, and cysts. Reversible hair loss has been noted. The effect of CC on fetal development is unclear. Neural tube defects have been reported but have not been confirmed by controlled studies. Adverse reactions of other ovulatory stimulants are listed in Table 58-4.

Contraindications. Contraindications for treatment with CC include undiagnosed vaginal bleeding, pregnancy, uterine fibroids, clinical depression, history of hepatic dysfunction or thromboembolic disease, and primary pituitary or ovarian failure. CC may cause existing ovarian cysts to enlarge. Contraindications to the use of other ovulatory stimulants are listed in Table 58-4.

Drug Interactions. There are no known significant drug interactions with CC. Danazol may inhibit patient response to CC, and CC may suppress response to ethinyl estradiol. There are no known drug interactions with human menopausal gonadotropin or hCG.

Luteal Phase Defects

Another leading cause of infertility is related to decreased progesterone levels in the luteal phase of the menstrual cycle (the phase after ovulation). With the decrease in circulating progesterone, the luteal phase is shortened and the progesterone-mediated endometrial changes vital to implantation do not occur. This condition is identified by low serum progesterone levels, taken through serum blood testing on days 21 through 25 of the menstrual cycle.

Women with inadequate luteal-phase progesterone output, called *luteal phase deficiency* (LPD), are treated with progesterone in vaginal, oral, or IM dosing (called luteal phase support). Progesterone supports the luteal phase that occurs immediately after ovulation. The extraneous progesterone is continued until 10 to 12 weeks' gestation, well after the placenta is functioning independently to support the pregnancy.

Progesterone cream or gel (Crinone 8%, Prochieve 8%) contains 90 mg of progesterone in a prolonged-release vaginal gel. It is administered intravaginally once or twice daily. Micronized progesterone (Endometrin 100 mg) is a vaginal suppository containing 100 mg of progesterone that is inserted twice or three times daily. Progesterone for injection comes in a 50 mg/mL vial; the usual dose is 50 mg daily (or 1 mL/day) given by deep IM injection. The progesterone comes in sesame oil, which makes it viscous and difficult to inject. An allergy to sesame seeds or oils should be determined by the nurse. Prometrium is micronized progesterone taken in an oral dose of 200 mg twice a day or 100 mg three times a day. It is used by practitioners treating women with infertility conditions caused by lack of progesterone output; however, this is an off-label use. Clinical trials are producing evidence that progestins and micronized progesterone are not teratogenic and cause no ill effects to a fetus. Nevertheless, these drugs carry a category X pregnancy warning. The use of progesterone after ovulation enhances successful conception and implantation in women with LPD.

For some women, the cause of LPD is the result of a premature LH surge. With an early LH surge, the follicle has not been given the time needed to mature and the cycle becomes anovulatory. A Gn-RH antagonist is used and can be given subcutaneously or by IM injection. Drugs that stimulate ovulation and their side effects are listed in Table 58-4.

Other Drug Treatments

Endocrine disorders include hyperprolactinemia and thyroid disorders. In women with hyperprolactinemia, an elevated level of prolactin is the causative factor of infertility. Prolactin is a hormone secreted by the anterior pituitary gland and elevated during pregnancy and postpartum to support milk production. Breastfeeding causes a natural rise in prolactin, and hyperprolactinemia can be seen in women who are breastfeeding or have recently discontinued breastfeeding.

Drug therapies, such as haloperidol (Haldol), metoclopramide (Reglan), methyldopa, reserpine, and long-term CHC use have been known to cause hyperprolactinemia. The most common cause of pathologic hyperprolactinemia is a small benign pituitary tumor called a *pituitary adenoma.* Most women, regardless of the cause of hyperprolactinemia, can be treated with the ergot derivative bromocriptine (Parlodel). Bromocriptine binds to dopamine receptors in the pituitary gland and inhibits prolactin secretion. Treatment continues until pregnancy is confirmed. Clomiphene can be introduced if needed after 2 months.

In addition, hypothyroidism or hyperthyroidism and adrenal dysfunction must be assessed and managed to attain euthyroid levels. Endometriosis can be treated with a course of danazol, leuprolide, or DMPA to suppress gonadotropin output.

Nursing Process
Patient-Centered Collaborative Care

Infertility

Assessment

- Assess general health history, including drug and herbal product use. Physical examination, including speculum and bimanual exam, are required. Assess patients' reproductive and sexual histories, with attention to history of abnormal Pap testing and treatment, history of vaginal infections and STIs and treatment, past use of contraception methods, pelvic surgery and past and present gynecologic abnormalities, and pregnancy and birth history and complications.
- Complete menstrual history including menarche; last menstrual period; length, duration, and flow of bleeding; and any signs or symptoms related to the menstrual cycle.
- Complete assessment of sexual practices including use of lubricants and timing and technique of intercourse.
- Assess couple's mental health status, with a referral to support group or counseling as needed. Infertility can be isolating, because many couples may have several peers who are pregnant or already have children.
- The couple will undergo an exhaustive battery of diagnostic tests to evaluate the cause of infertility. Once this is determined, conditions that contraindicate the treatment of choice are ruled out.
- It is particularly important that the couple's interpretation of their infertility be explored, along with its impact on their relationship. The nurse should help the couple discuss their feelings in a safe, supportive environment.

Nursing Diagnoses

- Deficient knowledge related to menstrual cycle, ovulation, conception, causes of infertility, prognosis, and assisted reproductive technologies
- Deficient knowledge related to treatment regimen and outcomes
- Ineffective sexuality pattern related to infertility
- Risk for sexual dysfunction related to assisted reproduction strategies
- Disturbed body image related to inability to conceive
- Situational low self-esteem related to infertility
- Anxiety related to infertility and treatment medication and procedures
- Powerlessness related to infertility diagnosis
- Decisional conflicts related to discrepancy between cultural and/or religious beliefs and assisted reproductive therapies
- Grieving related to loss of the plan to have a biologic child

Planning

- Patient will understand normal physiologic process of conception.
- Patient will identify basic concepts that increase fertility.
- Patient will adhere to medical regimen with minimal adverse effects physically, psychologically, emotionally, and spiritually.
- Patient will report adverse effects of treatment or pharmacologic therapy.
- Long-term goal is a successful pregnancy. If pregnancy cannot be achieved, patient will be able to consider alternatives and make the transition with confidence, relationship, and sense of self-worth intact.
- Patient will recognize that many treatment regimens for infertility must be repeated before successful conception is attained.

Nursing Interventions

General

- Initiate teaching to assist the patient (and her partner) in understanding the menstrual cycle, patterns and symptoms of ovulation, temperature changes with ovulation, specific physiologic signs of ovulation, use of ovulation predictor kits, and timing of sexual intercourse.
- Help the patient to understand the interrelationships among the menstrual cycle, ovulation, and coitus as they relate to conception.
- Advise the patient on the sexual techniques that enhance fertilization: placement of a pillow under the woman's hips during coitus, placement of the woman in a supine position with the hips elevated for about 30 minutes after her partner ejaculates.
- Initiate drug treatment regimens as prescribed by the provider. The patient and partner(s) will understand the treatment regimen and the expected outcomes of the treatment regimen.
- Provide the patient and her partner psychological counseling and support.

Specific

- Counsel the patient to report adverse effects such as abdominal pain or visual disturbances to her infertility specialist at once and to be cautious with tasks that require alertness. If she misses a dose of her medication, she should call her infertility specialist.
- Advise the patient that treatment increases the chance of multiple births.
- Ensure that patient understands the risks, benefits, and alternatives to pharmacologic therapy.

Patient Teaching

- Teach couples how to evaluate and record on a chart the woman's basal body temperature and changes in the cervical mucus. The first day of menses is day 1 of the cycle. Ovulation is predicted by a 0.5° F drop in basal body temperature followed by a 1° F rise. Over-the-counter diagnostic kits for assessing ovulatory status can also be used to time coitus. The couple is advised to engage in coitus frequently from 4 days before to 3 days after ovulation, but if the semen analysis reports a lowered sperm count, intercourse should occur every other day to maximize the man's sperm count.
- Advise male partner to wear boxer shorts during infertility treatment. Briefs hold the scrotum close to the body, and the heat reduces sperm count. For the same reason, if he is seated all day in his work, he is counseled to take a walk every hour or so.
- Advise male partner to avoid use of certain herbs that affect sperm production (Herbal Alert 58-1).
- Advise female partner to take medication at same time each day to maintain steady blood levels.

HERBAL ALERT 58-1

Herbs and Male Infertility

- *Saw palmetto* may cause metabolic changes in the sperm.
- *St. John's wort* affects sperm cells and causes decreased sperm motility and decreased viability.

- Encourage patient and partner to verbalize concerns and express feelings about treatment successes and failures.

Cultural Considerations

- A number of churches and religions do not support the use of reproductive technologies. Some couples may opt for adoption instead of reproductive assistance. Some may suffer additional anxiety if they go against their religious or cultural traditions and use reproductive technology.
- Some women may prefer to be examined only by a female health care provider. These women should remain covered as much as is possible and appropriate. Some patients combine traditional practices with conventional medicine; therefore, a complete history of nonpharmacologic therapy is needed.
- Use of a certified medical interpreter is necessary for individuals who have limited English skills; one of the same gender and culture is preferred for sensitive topics.
- In male-dominated cultures, the male partner may be unwilling to undergo an infertility evaluation, because infertility is viewed as a female problem.

Evaluation

- Successful outcomes of fertility treatment include avoidance of ovarian hyperstimulation and other untoward effects. Pregnancy that results in the birth of a live infant fulfills the objectives of treatment. If pregnancy is not achieved, intervention is aimed at helping the couple consider alternatives to childbearing without adverse impact on their self-esteem or harm to their relationship.

Drug Therapy for Male Infertility

For most infertile men, no specific causal factor can be identified. These patients are identified as having idiopathic **oligospermia** (semen with a low concentration of sperm) and **asthenospermia** (low sperm motility). There is no documented cost-effective treatment for this large group of men. Most drug regimens used have shown little promise in controlled studies, with the exception of using testosterone (or other hormonal) therapy to attain physiologic levels. Assisted reproductive techniques appear to hold more promise than drug therapy. Some surgical techniques, such as removal of a **varicocele** (an enlarged vein in the scrotal sac), can sometimes improve male infertility. Some herbal products contribute to male infertility problems (see Herbal Alert 58-1).

MEDICATIONS USED IN THE TREATMENT OF SEXUALLY TRANSMITTED INFECTIONS

Healthy sexual relationships are important to patients' health and well-being. The reproductive process, including pregnancy and birth, and the healthy expression of sexual intimacy between partners should be free from the threat of STIs. STIs are infections that are primarily transmitted through sexual contact. Pathogens implicated in STIs include bacteria, viruses, protozoal microbes, and certain parasites (Table 58-5).

Depending on the causative organism, STIs may be localized lesions affecting the skin or mucosa, or they may spread upward through the reproductive tract, increasing the risk for pelvic infection and infertility. Many are life-threatening and can be transmitted through pregnancy and birth to a fetus or neonate. Approximately one in four Americans will experience an STI in their lifetime. The incidence increases in communities with lower socioeconomic status and/or limited access to health care, in socially disparate communities, and in developing nations. Prevention and control of STIs are essential not only for the health of individuals, but also for the health of the community.

Transmission and Risk

Sexual transmission of pathogens can occur through breaks in the vaginal or cervical mucosa or the skin covering the shaft or glans of the penis. Each act of coitus results in tiny, friction-induced fissures on these surfaces. The problem is exacerbated by inadequate vaginal lubrication, which may occur after menopause, postpartum, just after menses, or when the woman is not sufficiently aroused before penetration.

Semen, sperm cells themselves, vaginal secretions, blood, and other body fluids can carry pathogens. Skin and mucosal lesions can be penetrated by microorganisms, and they can also shed them. Sexual contact can involve skin-to-skin, mouth-to-mouth, oral-genital, oral-anal, or hand-anal transmission of pathogens through breaks in the skin or mucosal surfaces or from inoculation by infectious body fluids. Anal penetration is particularly risky because of the likelihood of tissue trauma that results in the partner's exposure to enteric microorganisms. The risk for contracting an STI increases with substance abuse, imprisonment, sexual activity with a partner who has been imprisoned, sexual activity with individuals being paid for sex acts, and rape or sexual assault.

Patients engaging in sexual activity with multiple partners are at high risk for transmission of STIs, particularly HIV. Investigators at the National Institutes of Health suggest that the risk for acquiring STIs is markedly increased among individuals who have more than one sexual partner per year versus those who have fewer partners. Other high-risk practices are anal or vaginal intercourse without a condom, hand-anal contact and contact with menstrual blood during sexual activity, use of an enema before anal intercourse, and urination on broken skin or inside the body. Women have an increased incidence of acquiring an STI than men do. Risk-reducing behaviors for avoidance of STIs are listed in Box 58-2.

STIs are often manifested as multiple infections. Individuals undergoing treatment for one STI should be assessed for others, including HIV. This is especially true if genital or perianal ulcerations are present.

Vertical transmission, or perinatal infection, occurs when a fetus or neonate is infected by its mother. Microbes can travel up the reproductive tract from the vagina or cervix and

TABLE 58-5 PATHOGENS THAT CAUSE SEXUALLY TRANSMITTED INFECTIONS

	MODE OF TRANSMISSION		
PATHOGEN	**PREDOMINANTLY SEXUALLY TRANSMITTED**	**CAN BE TRANSMITTED BY SEXUAL CONTACT**	**SEXUAL CONTACT WITH ORAL-FECAL EXPOSURE**
Bacteria	*Calymmatobacterium granulomatis* *Chlamydia trachomatis* *Haemophilus ducreyi* *Neisseria gonorrhoeae* *Treponema pallidum* *Ureaplasma urealyticum*	*Escherichia coli** *Gardnerella vaginalis** *Haemophilus vaginalis* *Mobiluncus curtisii, Mobiluncus mulieris,* * *Peptostreptococcus* *Group B streptococcus** *Mycoplasma hominis**	*Shigella Campylobacter*
Viruses	Cytomegalovirus Hepatitis B Herpes simplex virus type 2 Human papillomavirus Molluscum contagiosum virus	Human T-lymphotrophic virus-1 Herpes simplex virus type 1 Epstein-Barr virus	HIV-1, HIV-2 Hepatitis C, D Hepatitis A
Protozoa, fungi, ectoparasites	*Trichomonas vaginalis* *Phthirus pubis* *Sarcoptes scabiei*	*Candida albicans** *Candida glabrada** *Candida tropicalus**	*Giardia lamblia* *Entamoeba histolytica*

*These microbial infections are frequently caused by alterations in the vaginal microecosystem or from an intestinal-to-vaginal route exposure but can be transmitted through certain sexual practices.

HIV, Human immunodeficiency virus.

BOX 58-2 RISK-REDUCING BEHAVIORS FOR AVOIDANCE OF STIS

- Patient screening for STIs at all gynecologic encounters
- Sexual abstinence or sexual contact with one partner who also is monogamous and tested for STIs before sexual intimacy
- Consistent and correct use of male or female condom
- Washing and urinating before and after intercourse
- Avoiding sex with someone who has genital or anal lesions
- Reducing use of alcohol or drugs, both of which impair judgment about sexual risk and may decrease immune response
- Avoiding sexual contact with HIV-infected persons, IV drug users, individuals who have present or past imprisonment, or sexual partners of all such individuals
- Never sharing hypodermic needles, razors, or any item that may be exposed to blood or body fluids
- Reporting, testing, and treating any exposure

STI, Sexually transmitted infection.

enter the intrauterine environment. Organisms that are of little consequence to healthy adults can be devastating to a fetus. Transmission can occur through contact with the mother's blood at birth or through breast milk, as in the case of HIV and hepatitis B virus. Many STIs, such as syphilis, are transmitted through the placenta and membranes. Others, the herpes simplex virus type 2 (HSV-2) for example, require actual contact by the infant with microorganisms in the birth canal. Because of the risk for blindness caused by *Chlamydia trachomatis* and *Neisseria gonorrhoeae,* erythromycin ointment is routinely administered in the eyes of neonates as prophylaxis. This is usually done in within the first hour after birth.

CDC guidelines for the primary treatment of various STIs are listed in Table 58-6. All sexual contacts of an infected individual should be informed of the exposure so they can be treated. Partners should refrain from sexual activity until each is clear of infection on follow-up evaluation or, at the very least, should use condoms.

STI Pathogens

Bacterial Pathogens

Sexually transmitted bacterial pathogens can be effectively treated with antibiotic therapy. These infections are found in the cervix, urethra, oropharynx, Bartholin's glands, and Skene's glands. They can cause a friable cervix and mucopurulent discharge. Many times they go undetected. Some women will complain of vaginal bleeding or spotting, increased discharge, and pelvic pain. Bacterial pathogens are a common cause of PID. Common bacterial pathogens are *Neisseria gonorrhoeae* and *Chlamydia trachomatis. Treponema pallidum* is a spirochete that causes syphilis. Syphilis, if not treated early in the infection process, is a systemic disease that has stages of active disease process and periods of dormancy. Left untreated, it can be fatal. The drug of choice for syphilis is Benzathine penicillin G, 2.4 million units given IM once in the early stage of syphilis, or, if the infective process is known to be greater than 1 year, Benzathine PCN G 2.4 million units IM once weekly for 3 weeks.

Viral Pathogens

Viral pathogens are not curable. Medication therapy is palliative. These include herpes simplex virus I (with cross-contamination from oral to genital) and herpes simplex virus II (HSV-1 or HSV-2), human papilloma virus (HPV), and HIV.

Human Papillomavirus. There are more than 80 different strands of HPV, about 30 of which are sexually transmitted. There are approximately 12 types, called "low-risk," that cause external lesions, and approximately 15 types, called "high-risk," that cause cervical lesions. It is now recognized that it is the high-risk types of HPV that cause cervical cancer in women, and up to 60% of sexually active women in their late teens or early twenties harbor the virus. For most young women, the virus is effectively suppressed by the immune system before causing cervical changes. However, if the HPV persists, it can cause the cervical cells to grow abnormally. The Pap test detects cervical dysplasia, which can be a precursor to cervical cancer if left untreated. While the Pap test can determine whether the cervical cells are abnormal, a digene test can detect the presence of 13 high-risk HPV types.

Gardasil is a vaccine indicated in male and female patients' age 9 to 26 years for the prevention of cervical cancer caused by HPV. Gardasil protects against HPV types 6 and 11, which cause genital lesions and have a lower risk for carcinoma, and HPV types 16 and 18, which are highly invasive and have the potential to cause cervical dysplasia. Gardasil should be administered in three separate IM injections in the upper arm over a 6-month period with the first dose at an elected date, the second dose 2 months after the first dose, and the third dose 6 months after the first dose. Gardasil does not substitute for routine cancer screening, and women who receive Gardasil should continue to undergo screening per standard of care.

Herpes Simplex Virus. HSV-2 is a recurrent viral infection that causes small, painful vesicles over the genital area, anus, thighs, and buttocks. Associated symptoms may be fever, pelvic pain, malaise, and other flulike symptoms. HSV-1 causes oral lesions ("cold sores") that can be transmitted to male or female genitalia during oral sexual practices. It is reported that 80% of adult individuals have oral herpes lesions. The length of time of viral eruption is shortened with antiviral medications; however, HSV remains recurrent and painful, and treatment is mostly palliative.

HIV. See Chapter 35 for drugs used to treat HIV.

Other Pathogens

Pediculosis refers to parasitic infections. *Pediculosis humanus capitus* are head lice, *pediculosis humanus corporus* are body lice, and *Phthirus pubis* are pubic lice. These infestations present with extreme pruritus of the body part or area where the lice are moving and laying egg cases. An infection that causes increased pruritus in the vaginal area with copious

TABLE 58-6 CURRENT GUIDELINES FOR PRIMARY THERAPIES FOR COMMON SEXUALLY TRANSMITTED INFECTIONS*

INFECTION	PRIMARY THERAPY	NOTES
Nongonococcal urethritis	Recommended: azithromycin 1 g PO in a single dose or doxycycline 100 mg PO b.i.d. for 7 d Alternative regimens: erythromycin base 500 mg PO q.i.d. for 7 d or erythromycin ethylsuccinate 800 mg PO q.i.d. for 7 d or levofloxacin 500 mg PO daily for 7 d or ciprofloxacin 300 mg PO b.i.d. for 7 d	Use of fluoroquinolones and tetracyclines is not recommended during pregnancy.
Chancroid	azithromycin 1 g PO in a single dose or ceftriaxone 250 mg IM in a single dose or ciprofloxacin 500 mg PO b.i.d. for 3 d or erythromycin base 500 mg PO t.i.d. for 7 d	Use compresses to remove necrotic material; clean ulcerative lesions t.i.d.
Chlamydia	Recommended: azithromycin 1 g PO for 1 d or doxycycline 100 mg PO b.i.d. for 7 d Alternative regimen: erythromycin base 500 mg PO q.i.d. for 7 d or erythromycin ethylsuccinate 800 mg PO q.i.d. for 7 d or ofloxacin 300 mg PO b.i.d. for 7 d or levofloxacin 500 mg PO daily for 7 d Pregnancy recommended: azithromycin 1 g PO for 1 dose or amoxicillin 500 mg PO t.i.d. for 7 d Pregnancy alternative: erythromycin base 500 mg PO q.i.d. for 7 d or erythromycin base 250 mg PO q.i.d. for 14 d or erythromycin ethylsuccinate 800 mg PO q.i.d. for 7 d or erythromycin ethylsuccinate 400 mg PO q.i.d. for 14 d Infants (ophthalmia neonatorum): erythromycin base or ethylsuccinate 50 mg/kg/d PO divided into 4 doses for 14 d	TOC needed 3-4 mo after initial treatment. Second course of therapy may be required.
Epididymitis	If likely cause GC or CT: ceftriaxone 250 mg IM for 1 d and doxycycline 100 mg PO b.i.d. for 10 d If likely cause enteric bacteria or allergy to above medications: ofloxacin 300 mg PO b.i.d. for 10 d or levofloxacin 500 mg PO daily for 10 d	Treat for gonorrhea; follow with treatment for nongonococcal urethritis.
Genital warts	Provider applied: cryotherapy or cryoprobe; repeat application q1-2wk or podophyllin 10%-25% in compound tincture of benzoin once/wk for 6 wk; wash off 4-6 hours after application. or trichloroacetic acid (TCA) or dichloroacetic acid (BCA) 80%-90% applied to visible warts and allowed to dry. Application is once/wk	Nothing eradicates HPV. Podophyllin contraindicated during pregnancy. Safety during pregnancy has not been established. Pregnancy category: C Pregnancy category: C Pregnancy category: C

TABLE 58-6 CURRENT GUIDELINES FOR PRIMARY THERAPIES FOR COMMON SEXUALLY TRANSMITTED INFECTIONS—cont'd

INFECTION	PRIMARY THERAPY	NOTES
	Patient applied: imiquimod 5% cream, applied h.s., 3 times/wk for up to 16 wk. Wash treatment area with soap and water 6-10 h after application. or sinecatechins 15% ointment applied to each wart t.i.d. for up to 16 weeks. or podofilox 0.5% solution or gel applied to warts with cotton swab b.i.d. for 3 d then discontinued for 4 d. Repeat cycle for 4 wk.	
Gonorrhea	Recommended: ceftriaxone 250 mg IM in a single dose *plus* either azithromycin 1 G PO in a single dose or doxycycline 100 mg PO b.i.d. for 7 d or Alternative if ceftriaxone not available: cefixime 400 mg PO in a single dose *plus* azithromycin 1 G PO in a single dose or doxycycline 100 mg PO b.i.d. for 7 d plus Test of cure in 1 week If cephalosporin allergy: azithromycin 2 G PO in a single dose *plus* Test of cure in 1 wk Pregnancy recommended: CDC suggests that cephalosporins be used for treatment of gonorrhea in pregnancy. ceftriaxone 250 mg IM in a single dose *plus* azithromycin 1 G PO in a single dose would be the treatment of choice Ophthalmia neonatorum: ceftriaxone 25-50 mg/kg IM/IV in a single dose; *max:* 125 mg Ophthalmia neonatorum prophylaxis: erythromycin (0.5%) ophthalmic ointment; 1 application each eye in a single dose	Patient should be concurrently treated for chlamydia. Fluoroquinolones are not recommended for treatment of GC infection due to high prevalence of fluoroquinolone resistance in these populations. Oral cephalosporins should not be given if parenteral cephalosporins are available. If it is given, a 1-wk follow-up for a test of cure is required. Use of fluoroquinolones and tetracyclines is not recommended during pregnancy.
Granuloma inguinale	azithromycin 1 g PO in a single dose or ceftriaxone 250 mg IM in a single dose or ciprofloxacin 500 mg PO b.i.d. for 3 d or erythromycin base 500 mg PO t.i.d. for 7 d	
Hepatitis A	No specific therapy exists.	Vaccine available as HAVRIX or VAQTA. Available in 2- and 3-dose series for eligible children 1-18 y. Available for patients older than 18 y with risk for obtaining HAV (men who have sex with men, drug users, sex workers, patients with HBV or HCV).
Hepatitis B	HAV and HBV are two STIs for which a vaccine exists.	CDC recommends vaccination of all infants and adolescents. ACIP recommends vaccination of all persons with recent STI and those with more than one partner in last 6 mo. Combined hepatitis A and B vaccine has been developed for adults.
Hepatitis C	Alpha interferon and oral agent ribavirin may be used to treat HCV chronic liver disease	No vaccine available.

TABLE 58-6 CURRENT GUIDELINES FOR PRIMARY THERAPIES FOR COMMON SEXUALLY TRANSMITTED INFECTIONS—cont'd

INFECTION	PRIMARY THERAPY	NOTES
Genital herpes simplex	First episode: acyclovir 400 mg PO t.i.d. for 7-10 d or acyclovir 200 mg PO five times/d for 7-10 d or famciclovir 250 mg PO t.i.d. for 7-10 d or valacyclovir 1 g PO b.i.d. for 10 d Recurrent episode: acyclovir 400 mg PO t.i.d. for 5 d or acyclovir 800 mg PO b.i.d. for 5 d or acyclovir 800 mg PO t.i.d. for 2 d or famciclovir 125 mg PO b.i.d. for 5 d or famciclovir 1,000 mg PO b.i.d. for 1 d or famciclovir 500 mg PO once followed by 250 mg PO b.i.d. for 2 d or valacyclovir 500 mg PO b.i.d. for 3 d or valacyclovir 1 g PO daily for 5 d Suppressive therapy: acyclovir 400 mg PO b.i.d. or famciclovir 250 mg PO b.i.d. or valacyclovir 500 mg PO daily or valacyclovir 1 g PO daily Neonatal: acyclovir 20 mg/kg IV q8h for 21 d	Types 1 and 2 cannot be distinguished clinically. No cure is known. Systemic disease is life-threatening to neonates; neurologic damage may result. Viral shedding is most prevalent when symptomatic; patient should avoid sexual relations at this time. Acyclovir, famciclovir, and valacyclovir may be used in pregnancy for HSV suppression therapy from gestational week 36 until delivery. Acyclovir and valacyclovir must be used with caution in first trimester of pregnancy. Visit the CDC website for information on treatment of HSV in immunosuppressed patients, including those with HIV/AIDS. For severe HSV disease, in-hospital parenteral (IV) therapy may be needed.
Lymphogranuloma venereum	doxycycline 100 mg PO b.i.d. for 21 d or erythromycin 0.5 g PO q.i.d. for 21 d	
Molluscum contagiosum	cryoanesthesia and curettage or caustic chemicals (podophyllin, trichloroacetic acid, silver nitrate) and cryotherapy	If all lesions not eradicated, may recur.
Mucopurulent cervicitis	azithromycin 1 g PO in a single dose or doxycycline 100 mg PO b.i.d. for 7-10 d	
Pelvic inflammatory disease (PID)	Inpatient regimen A: cefotetan 2 g IV q12h or cefoxitin 2 g IV q6h plus doxycycline 100 mg PO or IV q12h Inpatient regimen B: clindamycin 900 mg IV q8h plus gentamicin (loading dose) 2 mg/kg IM/IV followed by maint 1.5 mg/kg q8h Ambulatory care: ceftriaxone 250 mg IM in a single dose *plus* doxycycline 100 mg PO b.i.d. for 14 d	Often polymicrobial. This regimen may not treat anaerobes, pelvic mass, or IUD-associated PID.

Continued

TABLE 58-6 CURRENT GUIDELINES FOR PRIMARY THERAPIES FOR COMMON SEXUALLY TRANSMITTED INFECTIONS—cont'd

INFECTION	PRIMARY THERAPY	NOTES
	with or without metronidazole 500 mg PO b.i.d. for 14 d or cefoxitin 2 g IM in a single dose *plus* doxycycline 100 mg PO b.i.d. for 14 d with or without metronidazole 500 mg PO b.i.d. for 14 d or other parenteral third-generation cephalosporin (e.g., ceftizoxime or cefotaxime) *plus* doxycycline 100 mg PO b.i.d. for 14 d with or without metronidazole 500 mg PO b.i.d. for 14 d	
Proctitis	ceftriaxone 250 mg IM in a single dose, and doxycycline 100 mg PO b.i.d. for 7 d	
Pubic lice	permethrin 1% cream rinse: Apply to affected area, and wash off after 10 min or pyrethrins with piperonyl butoxide: Apply to affected area, and wash off after 10 min	Use lindane only if other therapy fails. Decontaminate clothes and bedding. Second treatment 7-10 d after first to kill newly hatched lice. Treat partner also.
Scabies	Recommended: permethrin cream 5% applied to all affected areas from neck down and washed off after 8-14 h or ivermectin 200 micrograms/kg PO, repeat in 2 wk. Alternative regimen: lindane 1% applied to all affected areas from neck down and thoroughly washed off after 8 h	
Sexual assault	ceftriaxone 250 mg IM in a single dose or cefixime 400 mg PO in a single dose *plus* metronidazole 2 g PO in a single dose plus azithromycin 1 g PO in a single dose or doxycycline 100 mg PO b.i.d. for 7 d	Tetanus booster and gamma globulin, as well as baseline HIV testing and follow-up, are recommended.
Syphilis	Primary, secondary, or <1 y duration (early latent syphilis): benzathine penicillin G, 2.4 million units IM in a single dose Unknown duration or >1 y (late latent syphilis): benzathine penicillin G, 7.2 million units divided in 2.4 million IM weekly in three doses Allergic to penicillin: see infectious disease specialist Infants and children: benzathine penicillin G 50,000 units/kg IM in a single dose, up to 2.4 million units.	Pregnant patients who are allergic to penicillin should be desensitized. Administration of Benzathine penicillin G in patient with syphilis may cause the Jarisch-Herxheimer reaction from the breakdown of the *T. pallidum* spirochete. This acute febrile reaction is often accompanied by headache, myalgia, and fever. In pregnant patients, this can cause preterm labor or fetal distress.
Trichomoniasis	Recommended: metronidazole 2 g PO in a single dose or tinidazole 2 g PO in a single dose Alternative regimen: metronidazole 500 mg PO b.i.d. for 7 d	Pregnant women can be treated after the first trimester. Metronidazole vaginal gel should not be given for trichomoniasis
	STIs have potentially serious sequela; partners of infected patients should be treated simultaneously to prevent reinfection.	Tindamax is contraindicated during the first trimester of pregnancy.

*The most recent guidelines and alternative treatments are available from *www.cdc.gov/STD/treatment.*

A, Adult; *ACIP,* Advisory Committee on Immunization Practices; *b.i.d.,* twice a day; *C,* child; *CDC,* Centers for Disease Control and Prevention; *d,* day; *GI,* gastrointestinal; *h,* hour; *HAV,* hepatitis A virus; *HBV,* hepatitis B virus; *HCV,* hepatitis C virus; *HIV,* human immunodeficiency virus; *HPV,* human papillomavirus; *h.s.,* at bedtime; *IM,* intramuscular; *IUD,* intrauterine device; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *min,* minute; *mo,* month; *PO,* by mouth; *q.i.d.,* four times a day; *STI,* sexually transmitted infection; *t.i.d.,* three times a day; *wk,* week; *y,* year; *>,* greater than; *<,* less than.

green-yellow, malodorous vaginal discharge is *Trichomonas vaginalis.* This microbe can be visualized under a microscope as one-celled protozoa with flagella. All pathogens that are sexually transmitted are shown in Table 58-5.

Because STIs can threaten reproductive health, neonatal health, fertility, and even life, early diagnosis and treatment are crucial but are less effective than prevention. For some, drug therapies may offer relief.

Nursing Process
Patient-Centered Collaborative Care

Sexually Transmitted Infections

Assessment

- Assess a medical history before gathering physical data. Address less-sensitive issues before more personal issues so trust can be established. Use the term *partner* when discussing sexual activity rather than value-laden terms such as *wife* or *boyfriend.* Include the following questions for all patients, regardless of gender or sexual orientation: "Do you have sex with women?" and "Do you have sex with men?"
- Assess patient history including chief complaint, description of course of illness, review of systems and general health history, gynecologic history including reproductive history and sexual history, review of lifestyle and social habits, and identification of allergies.
- Physical examination includes inspection and palpation of mouth, oropharynx, throat and lymph nodes, abdomen, and inguinal lymph systems. Also perform a physical examination of the genitalia and other points of inoculation. Allow men to swab themselves for cultures if preferred. Gonorrhea and chlamydia may also be obtained from a urine specimen.
- Laboratory tests include wet slide with microbe-specific setting agents, urinalysis, culture, Pap smear, complete blood count, syphilis serology, and HSV-2 and HSV-2 antibodies.

Nursing Diagnoses

- Deficient knowledge related to transmission and prevention of STIs
- Deficient knowledge related to pharmacologic treatment of STIs
- Noncompliance related to known prevention strategies
- Impaired tissue integrity related to lesions, ulcerations, and excoriations
- Pain related to inflammation and infection
- Situational low self-esteem related to potential stigma of diagnosis
- Ineffective sexuality patterns related to unsafe sex practices
- Risk for infection related to unsafe sex practices
- Medical diagnosis of HIV disease may bring these additional nursing diagnoses: (1) fatigue related to diagnosis, (2) anxiety related to potential outcome of disease, (3) anticipatory grieving related to fear of death, (4) risk for loneliness related to possible stigma of diagnosis, and (5) ineffective therapeutic regimen management/health maintenance related to focus on daily concerns with diagnosis

Planning

- Short-term goals include patient's adherence to treatment regimen and avoidance of adverse effects.
- Long-term goals include patient's return for follow-up evaluation and adoption of risk-reducing sexual behaviors.

Nursing Interventions

- Counsel patient about procedures performed during evaluation and how to administer prescribed medications and treatments. Review side effects and adverse reactions that require immediate intervention.
- Provide needed support as patient deals with the fact that infection is sexually transmitted.
- Advise patient to notify sexual partners so they can be evaluated and treated.
- Counsel patient to avoid sexual contact during treatment. At the least, patient should use condoms until both partners are shown to be clear of infection.
- Schedule follow-up visits from 4 days to 4 weeks later, depending on type of infection and treatment.
- Counsel patient about being tested for HIV.

Patient Teaching

- Review mode of transmission of STIs, relationship of all STIs to HIV infection, and how HIV risk is avoided.
- Counsel patient on effective use of both male and female condoms.
- Discuss condom use negotiation.
- Advise patient to plan periodic reproductive health checkups.

Cultural Considerations

- Some women prefer to be examined only by a female health care provider.
- Use a certified medical interpreter of same gender and culture, especially for sensitive topics.
- In male-dominated cultures, male patient may be unwilling to undergo testing or treatment.

Evaluation

- Intervention has been successful if the individual's infection is clear on reevaluation or, in the case of viral infections, the individual experiences quiescence of the virus.
- The infection is not transmitted to other individuals.
- The patient is able to avoid sexual practices that carry risk for acquiring STIs, including intercourse without the use of a condom.

CRITICAL THINKING CASE STUDY

DD is 32 years old and has never been pregnant. She has been diagnosed with infertility for 3 years. For the last year, she and her male partner TD have been trying to conceive without success. DD's nurse practitioner learns that DD has had three previous sexual partners and was treated for chlamydia at age 23 years; DD's partner TD was treated in the past for HSV. DD's menstrual history reveals an erratic pattern of unpredictable periods, occurring about every 3 to 4 months. DD and TD are referred to an infertility specialist by the nurse practitioner.

1. What is the relevance of DD's past sexual history to the current complaint?
2. Why would the infertility specialist consider cultures for *Chlamydia trachomatis* and *Neisseria gonorrhoeae* years after exposure?
3. What other tests would reveal damage resulting from STIs?
4. What is abnormal about DD's menstrual history? What about her menstrual pattern makes conception difficult? What are the possible diagnoses and pharmacologic treatments for the patient to help with conception? For what would the nurse want to observe when she examines the patient?
5. How can TD prevent DD from getting HSV? How can DD be tested for HSV?

After a complete evaluation of both DD and TD, metformin is prescribed for DD along with a course of clomiphene citrate.

6. What side effects can DD expect from these medications?
7. When should DD take the medications? What patient instructions are needed when clomiphene citrate is prescribed?
8. When should DD and TD have sexual intercourse to enhance the possibility of conception?
9. What other possible disease conditions can cause infertility?
10. DD becomes pregnant after four cycles on clomiphene citrate. What is one potential risk factor with this pregnancy?

DD gives birth to a boy after an uneventful pregnancy. She decides to breastfeed for 12 months. After discontinuing breastfeeding, her menstrual cycles return to a normal monthly pattern. However, she experiences fatigue, breast tenderness, and mood swings for a few days before her periods. She states that she cries and gets frustrated with her partner and child. She also has very painful periods and has missed work on several occasions because of her symptoms. She wants to wait 3 years before having another child.

11. What are the possible conditions that DD is experiencing? What nursing diagnoses accompany these conditions?
12. What type of complementary and alternative and/or drug therapies can be used to help DD with these conditions?
13. What method of contraception would be best for DD?
14. List the complete health teaching for DD.

NCLEX STUDY QUESTIONS

1. A patient with infertility asks the nurse what is causing her to have irregular cycles leading to her diagnosis of PCOS. What is the nurse's best response?
   a. "PCOS is caused by damage to the female reproductive tract by pathogens."
   b. "Increased levels of progesterone with PCOS cause the sperm to be unable to penetrate cervical mucus."
   c. "PCOS causes your body to have menstrual cycles in which ovulation does not occur."
   d. "PCOS is a state in which there is a lack of estrogen that interferes with the menstrual cycle."
2. A patient has been prescribed clomiphene citrate therapy by her doctor. The patient asks the nurse, "How does my new medicine work?" What is the nurse's best response to convey the mechanism of action of clomiphene citrate therapy to this patient?
   a. "This medication works by stimulating the ovaries, increasing the chance of ovulation."
   b. "This medication increases circulating progesterone levels."
   c. "This medication usually does not work on the first cycle."
   d. "This medication helps the ovaries form multiple follicles."
3. A patient at the STI clinic asks why he is not prescribed antibiotics. He has been diagnosed with HSV-2. The nurse's best response is based on what knowledge? (Select all that apply.)

a. Antibiotics will not lessen the symptoms of HSV.
b. HSV can be cured with antiviral medications only.
c. Antibiotics are used to successfully treat viral infections.
d. HSV symptoms may be relieved with palliative antiviral medications.
e. Antibiotics combined with antiviral medications are the best treatment for HSV-2 infections.

4. The nurse is reviewing risk factors for STIs with a patient. Which behavior has the least risk for acquiring an STI?
a. Abstinence
b. Use of a male condom
c. Sexual relations within a mutually monogamous relationship
d. Sexual relations with a previous IV substance user

5. The nurse prepares a class for high school students. What best describes why ulcerative STIs increase an individual's risk for HIV infection?
a. Ulcerative STIs decrease the amount of lubrication.
b. STIs are commonly associated with other high-risk behaviors.
c. STIs are only found in individuals with multiple sexual partners.
d. A break in the skin increases the transmission of pathogens.

6. The nurse is reviewing a patient's medications with her. The nurse knows that effective pharmacologic treatment for vulvovaginal candidiasis includes which drug?
a. metronidazole
b. fluconazole
c. metformin
d. ibuprofen

7. The nurse is meeting with a couple during the early phase of treatment for primary infertility. Which content would be appropriate to include in a generic teaching plan to be personalized for this couple? (Select all that apply.)
a. Ways to alleviate feelings of low self-esteem related to infertility
b. Sexual techniques that enhance fertilization
c. Recommended avoidance of guaifenesin
d. Necessity of repetitive treatment regimens before successful conception
e. Infertility is 100% curable.

Answers: 1, c; 2, a; 3, a, d; 4, a; 5, d; 6, b; 7, a, b, d.

UNIT XIX

Emergency Agents

This final unit focuses on adult and pediatric emergency drugs. Chapter 59 considers oxygen as an emergency drug and discusses pharmacologic treatment for five categories of emergency situations: (1) cardiac disorders, (2) intracranial hypertension, (3) poisoning, (4) shock, and (5) hypertensive crises and pulmonary edema. Specific drug protocols and dosages for the pediatric patient are included.

- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Describe indications for the emergency drugs listed in this chapter.
- Define the basic mechanism of action for each emergency drug.
- Discuss pertinent nursing considerations and actions specific for each agent.
- Explain how to administer the drugs properly.
- Describe significant adverse effects of each drug.

OUTLINE

Oxygen as an Emergency Drug
Emergency Drugs for Cardiac Disorders
  Aspirin
  Nitroglycerin
  Morphine Sulfate
  Atropine Sulfate
  Adenosine
  Diltiazem
  Amiodarone
  Lidocaine
  Procainamide
  Magnesium Sulfate
  Epinephrine
  Vasopressin
  Sodium Bicarbonate
Emergency Drug for Intracranial Hypertension
  Mannitol
Emergency Drugs for Poisoning
  Naloxone
  Flumazenil
  Activated Charcoal
Emergency Drugs for Shock
  Dopamine
  Dobutamine
  Norepinephrine
  Epinephrine
  Albuterol
  Diphenhydramine Hydrochloride
  Dextrose 50%
  Glucagon
Emergency Drugs for Hypertensive Crises and Pulmonary Edema
  Labetalol
  Nitroprusside Sodium
  Furosemide
  Morphine Sulfate

The drugs described in this chapter are first-line agents used to treat various medical emergencies. Nurses must have knowledge of the indications and actions of these agents, because medical and surgical emergencies can occur in virtually any area of nursing practice. Learning key nursing implications *before* a crisis situation enables the nurse to function at the highest possible level when the patient requires life-saving intervention.

At the end of each discussion of a group of emergency drugs is a summary prototype drug chart that contains dosages and indications. Common adult doses are listed in the drug charts; pediatric dosages may vary widely depending on the child's age and weight. For the purpose of drug dosing, advanced cardiac life support guidelines consider adults to be older than 8 years and children to be 8 years or younger; infants are younger than 1 year. The drug charts list only the most common indications and dosages for the emergency drugs discussed; they *do not* describe all possible uses and dosing regimens for the agents.

OXYGEN AS AN EMERGENCY DRUG

Oxygen can be classified as a drug, because it can have both beneficial and adverse effects on the body based on the amount and manner in which it is administered. Oxygen is essential to life—without it brain death begins within 6 minutes. Inadequate oxygenation produces **hypoxemia** (inadequate oxygen in the blood) and significant physiologic sequela to all body systems; therefore oxygen is a first-line drug for all emergency situations. Depending on the circumstances, adequate oxygenation may be all that is necessary to effectively treat physiologic disturbances such as chest pain, bradycardia, and cardiac dysrhythmias. Oxygen also acts as a potent pulmonary vasodilator and is beneficial for patients in heart failure.

Before the other pharmacologic agents discussed in this chapter are administered, ensure that the patient's airway and breathing are addressed to promote optimal oxygenation and ventilation. Giving a drug to treat a disorder brought on by hypoxemia without effectively correcting the cause of the hypoxemia is ineffective and ultimately does not produce the desired outcome. **Pulse oximetry**, which provides a digital display of oxygen saturation, is an essential monitoring tool that should be used in emergency situations to assess the adequacy of oxygenation and guide further interventions. Ideally oxygen saturation should be kept at or above 94%. It is important to recognize, however, that certain pathophysiologic states can make pulse oximetry readings inaccurate. These conditions include vasoconstriction, severe anemia, hypothermia, carbon monoxide poisoning, and shock.

The ambient room air contains approximately 21% oxygen. When patients breathe room air, the oxygen they inspire constitutes 21% of the total volume of gas they take in with each breath. This measure is termed the **fraction of inspired oxygen** (FiO_2). As a general rule, patients suffering from severe physiologic stress such as shock states, traumatic injury, acute myocardial infarction (AMI) with hemodynamic instability, and cardiac arrest initially require supplemental oxygen in high concentrations (i.e., an FiO_2 close to 100%). The initial emergency oxygen delivery devices of choice for these conditions include a nonrebreather mask with an oxygen reservoir (oxygen flow rate set at 10 to 15 L/min) for spontaneously breathing patients, and a bag-valve-mask device attached to an oxygen source at a flow rate of 15 L/min for patients who require assisted ventilation until definitive airway management and a mechanical ventilator are available.

Although caution must be exercised for patients with chronic obstructive pulmonary disease (COPD), who may lose their hypoxic respiratory drive when given oxygen in high concentration, oxygen should never be denied to a patient who needs it. In the case of COPD, the nurse should be prepared to ventilate the patient manually with a bag-valve-mask if respiratory depression or arrest occurs. Some patients in respiratory distress as a result of obstructive pulmonary disease or acute cardiogenic pulmonary edema may also benefit from oxygen therapy delivered through noninvasive mask ventilation via a CPAP or BiPAP circuit; these devices deliver oxygen via a positive-pressure mechanism.

Whatever the underlying injury or disease process, as the patient's condition stabilizes, the oxygen concentration should be decreased to achieve an arterial oxygen saturation of ≥94%. An FiO_2 above 50% for a prolonged period can lead to oxygen toxicity and other detrimental effects to the pulmonary system in both adults and children.

For emergency situations that do not involve severe physiologic stress (e.g., angina, dysrhythmias, pulmonary disease), supplemental oxygen delivered by nasal cannula at 1 to 6 L/min or by simple face mask at 6 to 10 L/min may have significant physiologic benefit. Young children may better tolerate a face tent with a high oxygen flow of 10 to 15 L than a face mask.

EMERGENCY DRUGS FOR CARDIAC DISORDERS

Drugs described in this section are indicated for cardiac emergencies such as angina, MI, disturbances of cardiac rate or rhythm, and cardiac arrest. In a resuscitation situation, the foundation of patient therapy is based upon proper oxygenation and ventilation, performance of optimal CPR, and application of electrical therapy (cardioversion and defibrillation) according to established treatment algorithms and standards. Pharmacologic agents are used as adjuncts in synchrony with these efforts when indicated to enhance the likelihood of a successful outcome. These drugs often must be prepared and administered rapidly. A sound knowledge base as well as easy access to the drugs and necessary equipment is essential for the best patient response in a cardiac emergency. Usually in an emergency, detailed personal, medical, drug, and herbal histories are unavailable (Herbal Alert 59-1). Treatment is based on patient presentation.

HERBAL ALERT 59-1

Herbs and Emergency Medications

In emergency situations, a detailed personal health history is often not available; therefore, treatment is based on patient presentation. Herbal products with anticoagulation properties or those that interact with catecholamines (which may cause hypertensive crisis) could adversely influence the effectiveness of medications used to treat emergency conditions.

Aspirin

Aspirin is a first-line emergency drug used to decrease platelet aggregation in the management of acute coronary syndromes and myocardial infarction. It is best administered at the onset of chest pain in doses of 160 to 325 mg orally. The patient should be asked to chew the tablet to speed absorption of the drug instead of swallowing the tablet whole. For patients experiencing nausea and vomiting, an aspirin rectal suppository in a dose of 300 mg can be given as an alternative. Aspirin is also indicated in the initial treatment algorithm for patients suffering from acute ischemic stroke who are not candidates for fibrinolytic therapy. Contraindications to aspirin administration include a true drug allergy, presence of cerebral hemorrhage on CT scan, and recent GI bleeding.

Nitroglycerin

Nitroglycerin dilates coronary arteries and improves blood flow to an ischemic myocardium. It is therefore the treatment of choice for **angina pectoris** (chest pain) and **myocardial infarction** (heart attack). Nitroglycerin is also considered a first-line drug in the management of patients with acute cardiogenic pulmonary edema due to its ability to decrease both preload and afterload. A focused medication history is essential prior to administration, even in emergency situations, because nitroglycerin in combination with drugs for erectile dysfunction (i.e., sildenafil [Viagra], vardenafil [Levitra], tadalafil [Cialis]) causes profound hypotension that may be refractory to treatment when taken within a 24- to 48-hour period. This combination is contraindicated. Nitroglycerin is available in sublingual, translingual aerosol spray, oral, topical, and intravenous (IV) forms. Only the sublingual, translingual aerosol spray, and intravenous preparations are discussed.

Sublingual nitroglycerin (0.3 to 0.4 mg) and the translingual aerosol spray (0.4-mg metered dose) preparations are indicated for patients experiencing an acute anginal attack who have a systolic blood pressure >90 mm Hg. The patient is taught to sit or lie down and moisten 1 sublingual nitroglycerin tablet with saliva and then place it under the tongue to allow it to dissolve slowly. If the chest pain is not relieved, sublingual nitroglycerin may be repeated at 3- to 5-minute intervals as long as the patient's systolic blood pressure remains >90 mm Hg until a total of 3 tablets has been taken. Patients prescribed the translingual aerosol preparation should be reminded that the spray should not be inhaled. Instead, it should be sprayed onto or under the tongue. The patient should be instructed not to swallow for approximately 10 seconds to allow absorption of the drug. As with sublingual nitroglycerin, up to 3 doses may be taken within 15 minutes. If pain persists despite 3 doses of the sublingual or aerosol forms, further interventions are necessary in an emergency or critical care setting. An ambulance should be called if the patient is outside the hospital. Blood pressure and heart rate must be monitored closely. Hypotension is a common adverse effect, especially the first time a patient takes nitroglycerin. **Tachycardia** (abnormally high heart rate in adults; >100 beats/min) or, uncommonly, bradycardia also may occur. Patients who take sublingual or translingual aerosol spray nitroglycerin while wearing a nitroglycerin patch may be at higher risk for hypotension. This situation warrants caution. Though tolerance to nitrates can develop in individuals who take nitroglycerin preparations daily and can offer some protection against hypotension, the nitroglycerin patch may need to be removed if blood pressure instability occurs. To prevent arcing and the potential for skin burns, the nitroglycerin patch must also be removed prior to cardioversion or defibrillation.

IV nitroglycerin is reserved for patients with unstable angina or an AMI. A continuous infusion is usually initiated at a rate of 10 to 20 mcg/min and increased by 5 to 10 mcg/min every 5 to 10 minutes, based on chest pain and blood pressure response. Continuous blood pressure and heart monitoring are required, because hypotension is a common adverse effect. Hypotension usually is treated by reducing or discontinuing the nitroglycerin infusion (see Chapter 42) and by placing the patient in a supine position with legs elevated if tolerated.

Morphine Sulfate

Morphine sulfate, a narcotic analgesic, is used to treat the chest pain associated with AMI. It also is indicated for acute cardiogenic pulmonary edema. Morphine relieves pain, dilates venous vessels, and reduces the workload on the heart. The standard dosage of morphine sulfate is 1 to 4 mg IV over 1 to 5 minutes, repeated every 5 to 30 minutes until chest pain is relieved. Because respiratory depression and hypotension are common adverse effects, the drug must be administered slowly and carefully titrated to achieve the desired therapeutic effects. Close patient monitoring is essential. It is important to realize that although morphine can produce respiratory depression, this agent can relieve the dyspnea caused by pulmonary edema. In this situation, respiratory distress is not a contraindication to morphine administration. The narcotic antagonist naloxone (Narcan) may be ordered to reverse the action of morphine if adverse effects pose a significant risk to the patient. The dose is 0.4 to 2 mg every 2 minutes as indicated (see Chapter 26).

Atropine Sulfate

Atropine sulfate is the primary agent indicated for the treatment of hemodynamically significant **bradycardia** (slow heart rate) and some types of **heart block** (e.g., atrioventricular block at the nodal level). Atropine acts to increase heart rate by inhibiting the action of the vagus nerve (parasympatholytic effect). Atropine sulfate is also used as an emergency drug to reverse the toxic effects of organophosphate pesticide and nerve agent exposure, which include bradycardia and excessive secretions.

In symptomatic bradycardia, atropine is administered IV in 0.5-mg doses at 3- to 5-minute intervals until the desired heart rate is achieved or until 0.04 mg/kg (not more than 3 mg) is given. Dosing in this manner may be repeated every 3 to 5 minutes up to a limit of 0.04 mg/kg (usually not more than 3 mg IV).

The adult IV atropine dose should never be less than 0.5 mg. Doses below 0.5 mg can produce a paradoxical bradycardia; at doses of 0.04 mg/kg or greater, vagal activity is considered completely blocked, and further atropine administration may have no benefit. However, in the case of organophosphate insecticide or nerve agent poisoning, *very high* doses of atropine may be necessary to counteract the pathophysiologic effects of these toxins. Therefore, the typical dosing range and limits do not apply under these circumstances.

If venous access is not available in an emergency situation, atropine sulfate should be administered through the intraosseous (IO) route. As a last resort, atropine may be given via the endotracheal tube (ETT) route if venous or intraosseous access cannot be achieved. The dose for endotracheal administration is 2 to 2.5 times the venous dose, diluted with normal saline or sterile water. Accordingly, 2 to 3 mg of atropine would be diluted in 10 mL of normal saline or sterile water and instilled deep into the ETT via a feeding tube attached to a syringe. After endotracheal administration, the patient should be ventilated vigorously with a bag-valve device to enhance absorption of the drug.

Continuous cardiac and blood pressure monitoring is essential for the patient who receives atropine sulfate. Significant adverse effects include cardiac dysrhythmias, tachycardia, myocardial ischemia, restlessness, anxiety, mydriasis, thirst, and urinary retention. See Chapter 19 for more information on atropine and other anticholinergics.

Pediatric Implications

The definition of bradycardia is variable and age-specific for the pediatric population. Knowledge of normal ranges is essential. Because cardiac output is dependent on heart rate in infants younger than 6 months, bradycardia (heart rate <100 beats/min for infants) must be treated. In fact, a heart rate <60 beats/min in an infant requires performance of CPR. Before administration of drugs, efforts always should be targeted first toward restoring adequate ventilation and oxygenation. For the neonate with a spontaneous heart rate of less than 80 beats/min, epinephrine 0.01 mg/kg IV or IO every 3 to 5 minutes as indicated should be given prior to atropine to elevate the heart rate, because stressed neonates quickly deplete their own stores of catecholamines. If these interventions do not produce the desired clinical response, then atropine is indicated in the presence of increased vagal tone or atrioventricular (AV) block. Other pediatric indications for atropine include management of organophosphate toxicity and as pretreatment to prevent bradycardia after succinylcholine administration during rapid-sequence intubation.

The pediatric dose of atropine is 0.02 mg/kg IV or IO. It is important to be cognizant that in the pediatric population, the minimum single dose is 0.1 mg and the maximum single dose is 0.5 mg IV. The maximum total pediatric dose is 1 mg in a child and 3 mg in an adolescent (defined as an individual who has reached puberty). NOTE: When referring to general age groupings of patients, *infants* are considered to be younger than 1 year; a *child* is considered to be age 1 year to adolescence (puberty), and an *adult* is considered to be an adolescent or older. See Chapters 7 and 11 for more information on pediatric medication dosing and monitoring.

Adenosine

Adenosine is the first-line drug of choice to treat **paroxysmal supraventricular tachycardia** (PSVT), a sudden, uncontrolled, rapid rhythm (exceeding 150 beats/min in adults) that originates above the ventricles. The goal is to convert PSVT to sinus rhythm. A natural substance found in all body cells, adenosine slows impulse conduction through the heart's AV node, interrupts dysrhythmia-producing reentry pathways, and restores a normal rhythm in patients with PSVT. Because the half-life is less than 5 seconds, adenosine is best administered rapidly via a peripheral IV site in the port most proximal to the patient as a 6-mg IV bolus over 1 to 3 seconds followed by a 20-mL saline flush. A 12-mg bolus may be given 1 to 2 minutes after the initial dose if PSVT persists. Higher doses are not recommended.

Nursing considerations include continuous cardiac monitoring and frequent assessment of vital signs. Adenosine is inhibited by methylxanthines such as caffeine and theophylline, so higher doses may be needed. Though usually transient, ventricular ectopy, bradycardia, flushing, chest pain, and dyspnea may occur. In addition, a short period of **asystole** may follow injection of adenosine (up to 15 seconds). Spontaneous cardiac activity typically resumes. Adenosine is contraindicated in patients with poison- or drug-related tachycardia, second- and third-degree heart block, and in patients with sick sinus syndrome, except those with functioning pacemakers. If the tachycardia originated in the ventricles, the patient could deteriorate and become hypotensive after adenosine administration. See Chapter 42 for more information on antidysrhythmic drugs.

Diltiazem

Diltiazem is a calcium channel blocker and is administered as an IV bolus to treat PSVT and to slow the ventricular response rate in atrial fibrillation or flutter. It is considered a second-line agent after adenosine. Diltiazem has less of a negative inotropic effect than other similar calcium channel blockers, but it has strong negative chronotropic actions. Therefore, IV diltiazem is less likely to cause cardiac depression, but is very effective in controlling heart rate.

The usual initial bolus dose of IV diltiazem is 0.25 mg/kg given over 2 minutes. If the supraventricular tachycardia does not convert to a normal sinus rhythm in 15 minutes, a second IV bolus of 0.35 mg/kg over 2 minutes may be necessary. For ongoing control of the ventricular rate in patients with atrial fibrillation or flutter, a continuous infusion of diltiazem is indicated at a dose range of 5 to 15 mg/hour, titrated according to the desired heart rate.

The nurse must carefully monitor blood pressure and heart rate and rhythm after administering IV diltiazem. Arrhythmias, bradycardia, heart block, and hypotension may develop. Diltiazem can elevate serum digoxin levels, predisposing the patient to digitalis toxicity. Simultaneous use of calcium channel blockers and beta blockers is contraindicated, because their negative inotropic and negative chronotropic effects are synergistic, causing myocardial depression and bradycardia. Other contraindications include preexisting heart block or sick sinus syndrome in the patient without a pacemaker, Wolff-Parkinson-White syndrome, and heart failure.

Amiodarone

The IV form of amiodarone is considered a first-line agent in the advanced cardiac life support algorithms for the treatment of life-threatening ventricular dysrhythmias and cardiac arrest. It has alpha- and beta-adrenergic blocking effects and acts on sodium, potassium, and calcium channels. Indications for use include pulseless ventricular tachycardia and ventricular fibrillation (after defibrillation and epinephrine), hemodynamically stable ventricular tachycardia, PSVT refractory to adenosine, ventricular rate control in atrial fibrillation, and pharmacologic treatment of atrial fibrillation.

Amiodarone is especially good for patients with impaired heart function who have atrial and ventricular dysrhythmias. It has been found to be more effective and to have fewer proarrhythmic properties than other agents with similar actions.

For patients who have a pulse (i.e., not in cardiac arrest), amiodarone 150 mg IV is given over 10 minutes, followed by a continuous infusion of 1 mg/min for 6 hours, then 0.5 mg/min over 18 hours as a maintenance infusion. For patients in cardiac arrest because of pulseless ventricular tachycardia or ventricular fibrillation, a dose of 300 mg diluted in 20 to 30 mL D_5W is given as a rapid infusion followed by a continuous infusion as described earlier. Additional doses of 150 mg may be given by rapid infusion if ventricular fibrillation or ventricular tachycardia recurs. The maximum daily dose is 2.2 g per 24-hour period.

Significant adverse effects include hypotension and bradycardia. The nurse should slow the infusion rate to prevent or treat these effects and be prepared to administer IV fluids, vasopressors, and agents to increase heart rate. A temporary pacemaker may be needed. Amiodarone has a very long half-life. It should not be given concurrently with pharmacologic agents that prolong Q-T interval on ECG (e.g., procainamide).

Pediatric Implications

Amiodarone is given for pulseless ventricular tachycardia and ventricular fibrillation as a 5 mg/kg rapid IV/IO bolus, which can be repeated up to a maximum dose of 15 mg/kg per 24 hours. For responsive children who have supraventricular (junctional and atrial) tachycardia and ventricular dysrhythmias with pulses present, amiodarone is given as a 5 mg/kg IV/IO loading dose (300 mg maximum) over 20 to 60 minutes and repeated to a maximum daily IV dose of 15 mg/kg per 24-hour period.

Lidocaine

Lidocaine may be used to treat significant ventricular **dysrhythmias** (irregular heartbeats) such as frequent premature ventricular contractions (PVCs), ventricular tachycardia, and ventricular fibrillation as an alternative agent to amiodarone. Lidocaine exerts a local anesthetic effect on the heart, thus decreasing myocardial irritability. Typically a patient with ventricular dysrhythmias is given a 1- to 1.5-mg/kg bolus of lidocaine, followed by 0.5 mg/kg to 0.75 mg/kg every 5 to 10 minutes until the dysrhythmia is controlled or a total dose of 3 mg/kg has been administered via the IV or intraosseous (IO) route. A continuous lidocaine infusion is initiated at a rate of 1 to 4 mg/min to maintain a therapeutic serum level. Lidocaine may also be administered via the endotracheal route in doses of 2 to 4 mg/kg.

Important nursing considerations for the patient receiving lidocaine include continuous cardiac monitoring and assessment for signs and symptoms of lidocaine toxicity (e.g., confusion, drowsiness, hearing impairment, cardiac conduction defects, myocardial depression, muscle twitching, and seizures). Because lidocaine is metabolized by the liver, patients with hepatic impairment, heart failure, shock, and advanced age (older than 70 years) are at higher risk for toxicity. In these patients, the lidocaine dose may need to be reduced by as much as 50% (see Chapter 42). Lidocaine is contraindicated as a *prophylactic* agent to prevent ventricular dysrhythmias following acute myocardial infarction.

Pediatric Implications

Ventricular ectopy is uncommon in children. Metabolic causes should be suspected if ventricular dysrhythmias occur. The pediatric dose of lidocaine is 1 mg/kg IV or via the IO route. The endotracheal tube (ETT) dose is 2 to 3 mg/kg. A maintenance infusion of 20 to 50 mcg/kg/min is

PROTOTYPE DRUG CHART 59-1

Lidocaine HCl

Drug Class Antidysrhythmic, class IB Trade Name: Xylocaine Pregnancy Category: C	**Dosage** A: IV/ IO: 1-1.5 mg/kg; may repeat 0.5 mg/kg q5-10min up to 3 mg/kg *(max)* ETT*: 2-4 mg/kg Drip: 1-4 mg/min C: IV/IO: Initially: 1 mg/kg; maint: 20-50 mcg/kg/min is recommended after bolus ETT*: 2-3 mg/kg Therapeutic range: 1.5-5 mcg/mL
Contraindications Hypersensitivity, advanced atrioventricular block Caution: Liver disease, heart failure, older adults	**Drug-Lab-Food Interactions** Drug: Increase effects with phenytoin, quinidine, procainamide, propranolol; increase risk for toxicity with cimetidine, beta-adrenergic blockers
Pharmacokinetics Absorption: IV Distribution: PB: 60%-80%; concentrates in adipose tissue Metabolism: t½: Initial: 7-30 min; terminal: 9-120 min Excretion: Through the liver	**Pharmacodynamics** PO: Onset: 45-60 sec Peak: 45-60 sec Duration: 10-20 min
Therapeutic Effects/Uses Antiarrhythmic drug to treat ventricular dysrhythmias such as premature ventricular contractions (PVCs), ventricular tachycardia, and ventricular fibrillation Mode of Action: Decreases automaticity; increases electrical threshold of ventricle	
Side Effects Drowsiness, confusion, dyspnea, lethargy, hypotension, nausea, vomiting	**Adverse Reactions** Life-threatening: Seizures, cardiac arrest

*Note: For endotracheal drug administration, dose should be 2 to 4 mg/kg in adults.

recommended following the bolus dose. Prototype Drug Chart 59-1 lists the pharmacologic data for lidocaine.

Procainamide

Procainamide is an antidysrhythmic agent prescribed for ventricular tachycardia, PVCs, and rapid supraventricular dysrhythmias unresponsive to adenosine. The typical IV loading dose of procainamide is 20 to 50 mg/min until the dysrhythmia is successfully treated. Other endpoints to procainamide administration include a total administration of 17 mg/kg of the drug, the development of hypotension, and specific changes on the ECG (e.g., widening of the QRS complex by 50% or more). A continuous maintenance infusion of 1 to 4 mg/min may be ordered following the loading dose.

The nurse must monitor vital signs and the ECG with particular attention to heart rate and rhythm, as well as blood pressure and the width of the QRS complex. Procainamide administration can cause severe hypotension. Heart block, rhythm disturbances, and cardiac arrest can occur. Procainamide is contraindicated in patients with **torsades de pointes,** an unusual polymorphic ventricular tachycardia often associated with a prolonged Q-T interval. The drug is eliminated via the kidneys; therefore patients with renal failure are at higher risk of adverse effects and often require a lower dosage.

Pediatric Implications

Procainamide is given to children for ventricular tachycardia that is recurrent or refractory to other measures and for supraventricular tachycardia. The loading dose is 15 mg/kg/IV or IO given over 30 to 60 minutes. The same monitoring guidelines, adverse effects, and contraindications described for adults are relevant in the pediatric population.

Magnesium Sulfate

Magnesium is an essential element in multiple enzymatic reactions in the body, including function of the sodium-potassium adenosine triphosphatase (ATPase) pump. Its physiologic effects can be likened to a calcium channel blocker with neuromuscular blocking properties. Hypomagnesemia is associated with the development of atrial and ventricular dysrhythmias.

The primary indications for emergency administration of magnesium sulfate are refractory ventricular tachycardia, refractory ventricular fibrillation, cardiac arrest associated with **hypomagnesemia** (low serum magnesium level), and life-threatening ventricular dysrhythmias from digitalis toxicity. It is also the drug of choice for the treatment of torsades de pointes.

Magnesium is administered by diluting 1 to 2 g (2 to 4 mL of a 50% solution) in 10 mL of D_5W. For cardiac arrest caused by hypomagnesemia or torsades de pointes, magnesium is given by direct IV push or via the IO route over 5 to 20 minutes. For patients experiencing torsades de pointes who are not in cardiac arrest, a magnesium infusion of 1 to 2 g diluted in 50 to 100 mL of D_5W can be given IV/IO over 5 to 60 minutes followed by a continuous infusion of 0.5 to 1g/h.

Although magnesium toxicity is rare, the nurse should monitor the patient's response to magnesium administration. Hypotension is the most common adverse effect when magnesium is given by rapid IV push. Other effects include mild bradycardia, flush, and sweating. True hypermagnesemia can cause diarrhea, respiratory depression, deep tendon reflex impairment, flaccid paralysis, and circulatory collapse. Because magnesium is eliminated via the kidneys, it should be administered with caution in patients with renal impairment.

Pediatric Implications

Indications for magnesium sulfate in pediatric patients include torsades de pointes, hypomagnesemia, and status asthmaticus that is unresponsive to beta-adrenergic agents. The magnesium sulfate dose is 25 to 50 mg/kg IV/IO (maximum dose of 2 g) given as a bolus for pulseless ventricular tachycardia, slowly over 10 to 20 minutes for ventricular tachycardia with pulses, and over 15 to 30 minutes for status asthmaticus.

Epinephrine

Epinephrine is a catecholamine with alpha- and beta-adrenergic effects. It has multiple uses. Emergency cardiac indications for administration of IV/IO epinephrine include profound bradycardia and hypotension, asystole, pulseless ventricular tachycardia, and ventricular fibrillation. Epinephrine is thought to improve perfusion of the heart and brain in cardiac arrest states by constricting peripheral blood vessels. In addition, epinephrine increases the chances for successful electrical countershock (defibrillation) in ventricular fibrillation. It is important to be aware that epinephrine is available in two primary concentrations: 1 : 1000 and 1 : 10,000. The 1 : 10,000 concentration is used when administering a single IV/IO dose of epinephrine. The 1 : 1000 form is used when preparing a continuous epinephrine infusion or when giving epinephrine via the IM or subQ route. The IM route has a more predictable absorption and is, therefore, preferred over the subQ route.

For profound bradycardia or hypotension, an epinephrine infusion may be ordered at 2 to 10 mcg/min. For asystole, pulseless ventricular tachycardia, and ventricular fibrillation, epinephrine is administered in 1-mg doses (1 : 10,000 solution) IV/IO every 3 to 5 minutes until the desired clinical response is achieved (usually return of effective cardiac activity). Epinephrine also may be given via the ETT route in doses of 2 to 2.5 mg diluted in 10 mL of normal saline.

Nursing implications for patients receiving epinephrine include constant cardiac and hemodynamic monitoring. Epinephrine can cause myocardial ischemia and cardiac dysrhythmias. Epinephrine should neve r be administered in the same site as an alkaline solution such as sodium bicarbonate, because alkaline solutions inactivate epinephrine. In addition, the presence of metabolic or respiratory acidosis decreases the effectiveness of epinephrine. All efforts should be made to correct acid-base imbalances in the patient. More drug information about epinephrine and other adrenergic drugs can be found in Chapter 18.

PREVENTING MEDICATION ERRORS

Epinephrine

- Ensure that the correct concentration (1 : 1000 vs. 1 : 10,000) is administered. The 1 : 10,000 preparation is meant to be given intravenously.

Pediatric Implications

The pediatric dose of epinephrine is 0.01 mg/kg (1 : 10,000 solution) given every 3 to 5 minutes IV or via the intraosseous (IO) route for cardiac arrest. The ETT dose of 0.1 mg/kg should be given using the 1 : 1000 solution.

Vasopressin

Vasopressin is indicated for the treatment of ventricular fibrillation that is refractory to defibrillation. It is found in the human body as endogenous antidiuretic hormone. The therapeutic dose is significantly higher than the amount normally present in humans. The effects of vasopressin as a cardiac emergency drug include nonadrenergic peripheral vasoconstriction. When used as an emergency agent, it appears to increase coronary artery perfusion during cardiopulmonary resuscitation (CPR) and to exhibit vasopressor effects. It is given to patients in cardiac arrest before or after epinephrine administration as a single 40 units IV or intraosseous dose. Although vasopressin can be given via the ETT route, a specific effective dose has not yet been established through research. Vasopressin is considered an adjunct to epinephrine and can replace either the first or second epinephrine dose in the cardiac arrest algorithm. Because vasopressin can induce myocardial ischemia and angina, it is contraindicated in responsive patients who have coronary artery disease (CAD), that is, patients with CAD who are not in cardiac arrest.

Pediatric Implications

Vasopressin is indicated for pediatric patients in cardiac arrest as well as those with catecholamine-resistant hypotension. The dosage for vasopressin in pediatric cardiac arrest is 0.4 to 1 unit/kg given as a bolus to a maximum dose of 40 units. A vasopressin infusion of 0.2 to 2 milliunits/kg/min can be initiated for catecholamine-resistant hypotension.

Sodium Bicarbonate

Sodium bicarbonate is prescribed to treat the metabolic acidosis that may accompany cardiac arrest and the hyperkalemia and acidotic states related to specific drug overdose situations. The current standard in resuscitation is to give sodium bicarbonate only *after* adequate ventilation, chest compressions, IV fluids, and drug therapy fail to correct the acidotic state. Sodium bicarbonate is not considered a first-line drug for the treatment of cardiac arrest; it is preferentially given based on results of arterial blood gas analysis when acidosis is severe. If a patient has been in arrest for a prolonged period and blood gas analysis is not available, sodium bicarbonate may be ordered as part of the ongoing resuscitation attempt. The standard initial IV dose of sodium bicarbonate is 1 mEq/kg. Subsequent dosing depends on arterial blood gas analysis.

Important nursing considerations relevant to sodium bicarbonate include careful monitoring of arterial blood gas analysis results. Sodium bicarbonate administration can lead to metabolic alkalosis, which may be very difficult to reverse and have deleterious physiologic effects. Catecholamines such as epinephrine, norepinephrine, and dopamine should not be infused in the same site as sodium bicarbonate, because they are inactivated by solutions containing sodium bicarbonate.

Table 59-1 lists emergency cardiac drugs and their dosages, uses, and considerations.

Pediatric Implications

If severe metabolic acidosis persists after attention has been directed at maintaining optimal ventilation and oxygenation, sodium bicarbonate may be given to the pediatric patient in a 1-mEq/kg dose via the IV or intraosseous route. It may also

TABLE 59-1 EMERGENCY CARDIAC DRUGS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
adenosine	A: IV: Initially: 6 mg; then 12 mg in 1-to 2 min if needed	For paroxysmal supraventricular tachycardia. Pregnancy category: C; PB: UK; t½: <10 sec
amiodarone IV	A: IV: with pulse: 150 mg over 10 min; then continuous infusion 1 mg/min, for 6 h; then 0.5 mg/min over 18 h. Cardiac arrest: 300 mg diluted in 20-30 mL D_5W rapidly; second dose 150 mg, followed by continuous infusion as above; *max:* 2.2 g/d. C: IV: without pulse: 5 mg/kg administered as rapid IV/IO bolus. With pulse: 5 mg/kg IV/IO loading dose over 20-60 min; repeated to max daily dose of 15 mg/kg	Part of ACLS algorithm for treatment of both atrial and ventricular dysrhythmias. Pregnancy category: C: PB: UK; t½: 26-107 d
atropine sulfate	IV/IO: 0.5-1 mg; can repeat up to 0.04 mg/kg or 3 mg (max) ETT: 2-3 mg diluted in 10 mL normal saline	For symptomatic bradycardia; asystole. Pregnancy category: C; PB: 60%-80%; t½: 2-3 h
diltiazem	IV: 0.25 mg/kg; repeat in 15 min at 0.35 mg/kg IV: drip: 5-15 mg/h	For supraventricular tachycardia and atrial fibrillation and flutter. Pregnancy category: C; PB: 80%; t½: 2-5 h
epinephrine	IV/IO: 0.5-1 mg; may be repeated q3-5min ETT: 2.0-2.5 mg diluted in 10 mL normal saline	For cardiac arrest. Pregnancy category: C; PB: UK; t½: UK
lidocaine	See Prototype Drug Chart 59-1.	
magnesium sulfate	Dilute 1-2 g (2-4 mL of 50% solution) in 10 mL of D_5W. Give IV/IO in cardiac arrest over 5-20 min. Torsades de pointes: 1-2 g diluted in 50-100 mL of D_5W given IV over 5-60 min, followed by continuous infusion of 0.5-1 g/h	For hypomagnesemia, ventricular tachycardia, and ventricular fibrillation. Drug of choice for torsades de pointes. Rapid infusion can cause hypotension. Pregnancy category: D; PB: 25%-35%; t½: 30 min
morphine sulfate	IV: 1-4 mg q5-30min	For chest pain, unstable angina, pulmonary edema. Pregnancy category: C; PB: 35%; t½: 2-2.5 h
nitroglycerin	SL: 0.3-0.4 mg; Translingual aerosol spray: 0.4-mg metered dose, up to 3 sprays in 15 min onto or under tongue IV: drip: 10-20 mcg/min, increased 5-10 mcg/min q5-10 min (titrated)	For chest pain, angina, unstable angina, MI. Hypotension can occur; contraindicated in patients taking drugs for erectile dysfunction (e.g., Viagra). Pregnancy category: C; PB: 60%; t½: 1-4 min
procainamide HCl	IV: 20-50 mg/min; *max:* 17 mg/kg Recognize endpoints: Hypotension QRS widens >50% Total dose of 17 mg/kg given Drip: 1-4 mg/min	For PVCs, ventricular tachycardia, ventricular fibrillation, atrial dysrhythmias. Pregnancy category: C; PB: 20%; t½: 3-4 h
sodium bicarbonate	IV: Initially: 1 mEq/kg; then dose based on ABG results	For metabolic acidosis. Pregnancy category: C; PB: UK; t½: UK
vasopressin	A: IV/IO/ETT: single 40-unit dose before or after epinephrine administration	For ventricular fibrillation refractory to defibrillation. Contraindicated in responsive patients with CAD. Pregnancy category: C; PB: UK; t½: 10-20 min

A, Adult; *ACLS,* Advanced Cardiac Life Support; *C,* child; *CAD,* coronary artery disease; *d,* day; *ETT,* endotracheal tube; *h,* hour; *IO,* intraosseous; *IV,* intravenous; *max,* maximum; *MI,* myocardial infarction; *min,* minute; *PB,* protein-binding; *PVC,* premature ventricular contraction; *sec,* second; *SL,* sublingual; *t,* half-life; *UK,* unknown; *>,* greater than; *<,* less than.

be given as treatment for a tricyclic antidepressant overdose. Sodium bicarbonate is hyperosmolar and should be diluted from an 8.4% solution (1 mEq/mL) to a 4.2% solution (0.5 mEq/mL) for infants.

EMERGENCY DRUG FOR INTRACRANIAL HYPERTENSION

Mannitol

Mannitol is an osmotic diuretic used in emergency, trauma, critical care, and neurosurgical settings to treat cerebral edema and to reduce increased intracranial pressure (intracranial hypertension), which may occur following head trauma, neurosurgery, malignancy, and other types of intracranial pathology. Mannitol may be given as an IV bolus or via a continuous drip. The usual initial bolus dose of mannitol is 1g/kg IV of a 20% to 25% solution. Subsequent dosing is highly variable and is influenced by serum osmolality. In general, mannitol is held when serum osmolality exceeds 310 to 320. Mannitol is highly irritating to veins. The nurse must use a filter needle when administering mannitol, because crystals may form in the solution and syringe and be inadvertently injected. When a filter needle is used to draw up the mannitol, a *new* filter needle *must* be used to administer the mannitol IV. In addition, the nurse should carefully assess the patient's neurologic status; monitor laboratory studies, including electrolytes and serum osmolality; and keep accurate intake and output records to assess fluid volume status, because diuresis may be substantial. Prototype Drug Chart 59-2 lists the pharmacologic data for mannitol.

EMERGENCY DRUGS FOR POISONING

Although there are numerous antidotes for specific types of poisoning, the drugs presented in this section are the most commonly prescribed agents in cases of drug overdose and ingestion of toxic substances, with pertinent exceptions noted. Particular attention must be given to administration guidelines to achieve the best possible clinical outcome for the patient. These drugs are cross-referenced to their specialty chapters.

Naloxone

Naloxone is classified as an opiate antagonist. It reverses the effects of all opiate drugs (e.g., morphine, meperidine, codeine, propoxyphene, heroin) by competitively binding to opiate receptor sites in the body. Naloxone is indicated for individuals who have taken an overdose of opiate drugs, those experiencing respiratory or cardiovascular depression from therapeutic doses of opiates given in a health care setting, and those brought to the emergency department in a coma of unknown etiology (which may be drug induced).

PROTOTYPE DRUG CHART 59-2

Mannitol

Drug Class Osmotic diuretic Trade Name: Osmitrol Pregnancy Category: C	**Dosage** A: IV: Initially 1g/kg of 20%-25% sol as a bolus Highly individualized dosing
Contraindications Hypersensitivity, severe dehydration Caution: Pregnancy, breastfeeding, current intracranial bleeding	**Drug-Lab-Food Interactions** Drug: May decrease effectiveness with lithium
Pharmacokinetics Absorption: IV Distribution: PB: Confined to extracellular space Metabolism: $t\frac{1}{2}$: 100 min Excretion: In urine	**Pharmacodynamics** Decrease in intracranial pressure: IV: Onset: 30-60 min Peak: 1 h Duration: 6-8 h Diuresis: IV: Onset: 1-3 h Peak: 1 h Duration: 6-8 h
Therapeutic Effects/Uses To treat increased intracranial pressure, cerebral edema Mode of Action: Inhibits reabsorption of electrolytes and water by affecting pressure of glomerular filtrate	
Side Effects Temporary volume expansion, hyponatremia/hypernatremia, hypokalemia/hyperkalemia, dehydration, blurred vision, dry mouth	**Adverse Reactions** Pulmonary congestion, fluid/electrolyte imbalances Life-threatening: Convulsions

A, Adult; *h,* hour; *IV,* intravenous; *min,* minute; *PB,* protein-binding; *sol,* solution; *$t\frac{1}{2}$,* half-life.

The typical dose of naloxone for actual or suspected opiate overdose in adults is 0.4 to 2 mg IV administered every 2 minutes until the patient's condition improves to an acceptable level. If there is no improvement within 10 minutes after 10 mg of the drug has been injected, nonopiate drugs or disease must be suspected. Although naloxone should be administered IV in emergency situations, it also may be given via the intramuscular (IM), intraosseous (IO), or subcutaneous (subQ) routes if IV access is not readily obtainable. In addition, naloxone appears to have efficacy when given via the intranasal route in doses of 1 mg per nostril, which reduces the risk of needlestick injuries to health care personnel.

Because most opiate drugs have a longer duration of action than naloxone, the nurse must monitor the patient closely for signs and symptoms of recurrent opiate effects such as respiratory depression and hypotension. In this situation, naloxone administration may need to be repeated several times or a continuous IV infusion ordered. Naloxone has no major adverse effects, but can precipitate withdrawal symptoms in patients addicted to opiate drugs and rarely cause anaphylaxis. In addition, pulmonary edema has been reported following naloxone administration in patients who have had an overdose of morphine (see Chapter 26). Nurses also must be on guard for combative or violent behavior following naloxone administration, especially in patients who have overdosed on an illicit drug; having security personnel available to stand by is prudent. Prototype Drug Chart 59-3 lists the pharmacologic data for naloxone.

Pediatric Implications

For narcotic reversal in children, give 0.01 to 0.1 mg/kg, repeating the drug as necessary based upon desired therapeutic effects up to 2 mg. Naloxone can be administered as an IV bolus or continuous infusion, as well as IO, IM, or subQ in children.

Flumazenil

Flumazenil is the reversal agent for the respiratory depressant and sedative effects of benzodiazepine medications (e.g., diazepam [Valium], midazolam [Versed], chlordiazepoxide [Librium]). It is administered to counteract the effects of benzodiazepines given as sedative or anesthetic agents, as well as to treat accidental or intentional benzodiazepine overdose. Flumazenil does not reverse the central nervous system (CNS) depressant effects of nonbenzodiazepine agents such as alcohol, opiates, and barbiturates and may not reverse amnesia induced by benzodiazepines.

PROTOTYPE DRUG CHART 59-3

Naloxone HCl

Drug Class Narcotic antagonist Trade Name: Narcan Pregnancy Category: B	**Dosage** IV/IM/IO/subQ: 0.4-2 mg; repeat every 2-3 min as indicated
Contraindications Hypersensitivity, respiratory depression Caution: Opiate-dependent patients, cardiac disease, breastfeeding neonates of opiate-dependent mothers	**Drug-Lab-Food Interactions** Drug: Naloxone can precipitate withdrawal in a patient dependent on narcotic analgesics Lab: Urine vanillylmandelic acid (VMA), 5-hydroxyheptadecatrienoic acid (5-HIAA), urine glucose
Pharmacokinetics Absorption: IM/subQ: Well absorbed Distribution: PB: UK Metabolism: $t_{1/2}$: Adults: 1-4 h; neonates: 1-3 h Excretion: In urine metabolites	**Pharmacodynamics** subQ/IM: Onset: 2-5 min Peak: UK Duration: 1-4 h IV/IO: Onset: 1-2 min Peak: UK Duration: 1-4 h
Therapeutic Effects/Uses To treat respiratory depression caused by narcotics; to treat narcotic-induced depressant effects and narcotic overdose Mode of Action: Blocks effects of narcotics by competing for receptor sites	
Side Effects Negligible pharmacologic effect without narcotics in body	**Adverse Reactions** Nausea, vomiting, tremulousness, sweating, tachycardia, elevated blood pressure Life-threatening: Atrioventricular fibrillation, pulmonary edema (with overdose of morphine)

h, Hour; *IV,* intravenous; *IM,* intramuscular; *min,* minute; *PB,* protein-binding; *subQ,* subcutaneous; $t_{1/2}$, half-life; *UK,* unknown.

TABLE 59-2 EMERGENCY DRUGS FOR POISONING

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Flumazenil	IV: Initial dose 0.2 mg over 15 sec. Additional doses of 0.3-0.5 mg over 30 sec every 1 min as indicated. For resedation, may repeat at 20-min intervals to total dose of no more than 3 mg.	Reversal agent for benzodiazepine overdose; may precipitate seizures in patients with long-term use or abuse of benzodiazepines and those with seizure disorders; may precipitate emergent reactions. Pregnancy category: C; PB: 50%; $t\frac{1}{2}$: Variable (40-80 min)
naloxone (Narcan)	See Prototype Drug Chart 59-3.	
activated charcoal	A/C: 1-2 g/kg PO	For poisoning. Onset: <1 min. Pregnancy category: C; PB: NA; $t\frac{1}{2}$: NA

A, Adult; *C,* child; *IV,* intravenous; *min,* minute; *NA,* not applicable; *PB,* protein-binding; *PO,* by mouth; *sec,* second; $t\frac{1}{2}$, half-life; <, less than.

For suspected benzodiazepine overdose, flumazenil is given IV in an initial dose of 0.2 mg over 15 seconds. A second dose of 0.3 mg may be given over 30 seconds. A third dose and subsequent doses of 0.5 mg IV may be given every minute until the desired clinical response is achieved or until a total dose of 3 mg is given within any given hour. If sedation occurs again, doses of flumazenil may be repeated at 20-minute intervals (not to exceed 1 mg at a time) to a total hourly dose of no more than 3 mg IV.

Nursing considerations include careful assessment of respiratory rate and effort, blood pressure, and mental status. If the benzodiazepine is reversed too rapidly, patients may have emergence reactions in which they become agitated and confused and experience perceptual distortions. Because seizures are precipitated by benzodiazepine withdrawal, seizure precautions must be implemented for patients at risk (those with long-standing benzodiazepine use or abuse) or for those who have a known seizure disorder.

Activated Charcoal

Activated charcoal may be prescribed for poisoning as a means to prevent absorption of toxins into the body if the ingested substance is known to be affected by charcoal in the gastrointestinal (GI) tract. A poison control center should be contacted as soon as possible to help guide medical therapy. In cases of known or suspected poisoning, activated charcoal is prepared as a slurry and given to the patient orally or via a gastric tube, ideally within 30 minutes to 1 hour of ingestion, sometimes following gastric lavage. The dose is dependent on the amount of poison ingested; the typical adult and pediatric dose is 1 to 2 g/kg, up to 25 to 60 g per dose. Activated charcoal dosing may need to be repeated for certain types of poisoning, particularly from agents such as salicylates, slow-release drug preparations, and *Amanita phalloides* (death cap mushrooms), to name a few.

Since vomiting is a common adverse reaction, patients with an impaired gag reflex and/or an impaired mental status are at high risk for aspiration after ingesting activated charcoal. Aspiration pneumonia and death can occur. To promote safety, these patients may need intubation for airway protection followed by installation of the activated charcoal via a gastric tube. Activated charcoal should not be administered with milk products, because they decrease its adsorptive properties. Activated charcoal is ineffective and should not be given to patients who have ingested some forms of pesticides, hydrocarbons, alcohol, acids or alkalis, lithium, solvents, and iron supplements. A **cathartic** (a purgative resulting in bowel movements) may be ordered following administration of activated charcoal to speed elimination of the charcoal-toxin complex from the body. The patient should be told that charcoal produces black stools.

Table 59-2 lists the emergency drugs for poisoning and their dosages, uses, and considerations.

EMERGENCY DRUGS FOR SHOCK

Drugs may be required to elevate blood pressure and to improve cardiac performance in various types of shock states. Therapeutic agents described in this section are primarily indicated in conditions such as cardiogenic shock, neurogenic shock, septic shock, anaphylactic shock, and insulin shock. A noteworthy exception to the list is **hypovolemic shock** (shock resulting from loss of blood or fluid volume); drugs should never be used as the primary therapy to correct the hypotension associated with this condition. Administration of fluids or blood products or both is the only acceptable initial means to treat hypovolemic shock. However, if hypotension persists after appropriate volume resuscitation, vasoactive drugs may be necessary to elevate and sustain blood pressure. The drugs that follow are cross-referenced to their specialty chapters.

Dopamine

Dopamine is a sympathomimetic agent often used to treat hypotension in shock states. Dopamine may also be used to increase heart rate (beta1 effect) in bradycardic rhythms when atropine has not been effective. The dose range is 2 to 20 mcg/kg/min. Dopamine enhances cardiac output by increasing myocardial contractility and increasing heart rate (beta$_1$ effect) and elevates blood pressure through vasoconstriction (alpha-adrenergic effect). Alpha effects predominate at higher doses—vasoconstriction of renal, mesenteric, and peripheral blood vessels occurs. Such vasoconstriction, although sometimes necessary to maintain adequate blood pressure in severe shock, can lead to poor organ and tissue perfusion, decreased cardiac performance, and reduction of urine output. The lowest effective dose of dopamine should be used. Patients must be weaned gradually from dopamine; abrupt discontinuation of the infusion can cause severe hypotension.

Dopamine is typically mixed as a concentration of 400 to 800 mg in 250 mL D_5W or normal saline solution and administered IV by an electronic infusion pump for precision, preferably in a central vein. Sodium bicarbonate will inactivate dopamine; it should not be infused in the same IV line. Continuous heart and blood pressure monitoring is essential. The nurse must carefully document vital signs, the cardiac rhythm and intake and output as prescribed. Significant adverse effects include tachycardia, dysrhythmias, myocardial ischemia, nausea, and vomiting. The IV site must be assessed hourly for signs of drug infiltration; **extravasation** (escape into tissues) of dopamine can produce tissue necrosis that may necessitate surgical debridement and skin grafting. If extravasation occurs, the site should be injected in multiple areas with phentolamine (Regitine), 5 to 10 mg diluted in 10 to 15 mL of normal saline, to reduce or prevent tissue damage. Prototype Drug Chart 59-4 lists the pharmacologic data for dopamine.

PREVENTING MEDICATION ERRORS

Do not confuse…

- **dopamine** with **dobutamine**

Dobutamine

Dobutamine is a sympathomimetic drug with beta adrenergic activities. The $beta_1$ effects include enhancing the force of myocardial contraction (positive inotropic effect) and increasing heart rate (positive chronotropic effect). The $beta_2$ effects produce mild vasodilation. Dobutamine is indicated in shock states when improvement in cardiac output and overall cardiac performance is desired. Blood pressure is elevated only through the increase in cardiac output. The usual IV dose range of dobutamine is 2 to 20 mcg/kg/min administered via an electronic infusion pump for precision. A typical concentration of dobutamine is 250 mg to 1000 mg mixed in 250 mL of D_5W or normal saline. Like dopamine, dobutamine administration should be tapered gradually as the patient's condition warrants; abrupt discontinuation can precipitate clinical deterioration.

Continuous cardiac and blood pressure monitoring are required for patients receiving dobutamine infusions. Adverse effects are dose-related and include myocardial ischemia, tachycardia, dysrhythmias, headache, nausea, and tremors. The nurse must carefully monitor intake and output and assess for any signs or symptoms of myocardial ischemia such as chest pain or development of dysrhythmias.

Norepinephrine

Norepinephrine is a catecholamine with extremely potent vasoconstrictor actions (alpha-adrenergic effect). It is used in

PROTOTYPE DRUG CHART 59-4

Dopamine HCl

Drug Class Adrenergic Trade Name: Dopamine Pregnancy Category: C	**Dosage** A: IV: Drip: 2-20 mcg/kg/min (>10 mcg/kg/min may be ordered if lower doses are ineffective)
Contraindications Hypersensitivity, tachydysrhythmias, ventricular fibrillation, pheochromocytomas Caution: Safety in children is not known.	**Drug-Lab-Food Interactions** Drug: May result in hypertensive crisis when used within 2 wk of MAOIs; concurrent IV administration of phenytoin may result in hypotension and bradycardia; sodium bicarbonate solutions inactivate dopamine—do not administer through same IV line
Pharmacokinetics Absorption: IV Distribution: PB: UK Metabolism: $t\frac{1}{2}$: 2 min Excretion: In urine	**Pharmacodynamics** IV: Onset: 1-2 min Peak: <5 min Duration: <10 min
Therapeutic Effects/Uses To treat hypotension in shock states after adequate fluid and/or blood product resuscitation; to increase heart rate in atropine-refractory bradycardia. Mode of Action: Stimulates receptors to cause cardiac stimulation; increases systemic vascular resistance	
Side Effects Palpitations, tachycardia, hypertension, ectopic beats, angina, IV line site irritation, piloerection, nausea, vomiting	**Adverse Reactions** Cardiac dysrhythmias, azotemia, tissue sloughing (from extravasation) Life-threatening: MI, gangrene in extremities (from vasoconstriction)

A, Adult; *IV*, intravenous; *MAOIs*, monoamine oxidase inhibitors; *MI*, myocardial infarction; *min*, minute; *PB*, protein-binding; $t\frac{1}{2}$, half-life; *UK*, unknown; *wk*, week; *>*, greater than; *<*, less than.

shock states, often when drugs such as dopamine and dobutamine have failed to produce adequate blood pressure, or as an alternative to dopamine. Like high-dose dopamine, the peripheral vasoconstriction that results has the potential to impair cardiac performance and decrease organ and tissue perfusion. In general, 4 to 8 mg of norepinephrine are added to 250 mL D_5W or normal saline solution and infused at 0.5 to 35 mcg/min (titrated) for adults. Continuous cardiac monitoring and precise blood pressure monitoring are required. The drug must be tapered slowly; abrupt discontinuation can result in severe hypotension.

Nursing actions and considerations are the same as those for dopamine. Norepinephrine should not be used as an initial therapy to treat hypotension in hypovolemic patients; fluid, blood, or both must be administered to restore adequate volume first. Adverse effects of norepinephrine include myocardial ischemia, dysrhythmias, and impaired organ perfusion. Extravasation of norepinephrine causes tissue necrosis, so attention to the IV site is essential. If extravasation occurs, the area should be infiltrated with phentolamine, as described for dopamine.

Epinephrine

Epinephrine is the drug of choice in the treatment of **anaphylactic shock,** an allergic response of the most serious type, brought about by an antibody-antigen reaction. Anaphylactic shock can be fatal if prompt treatment is not initiated. Severe bronchoconstriction and hypotension resulting from cardiovascular collapse are its hallmarks. Epinephrine is also indicated for an acute, severe asthmatic attack.

Administration of epinephrine causes bronchodilation, enhanced cardiac performance, and vasoconstriction to increase blood pressure. In severe asthma and anaphylactic shock, epinephrine is given in a dose range of 0.2 to 0.5 mg IM or subQ for adults via a tuberculin syringe for accuracy (1:1000 solution). IM administration is preferable to subQ administration, because the IM route has a more predictable pattern of absorption. As an alternative, epinephrine can be given in a dose of 0.1 to 0.25 mg IV over 5 to 10 minutes (1:10,000 solution). Epinephrine administration can be repeated every 5 to 15 minutes if necessary.

The patient who receives epinephrine must be closely monitored for tachycardia, cardiac dysrhythmias, hypertension, and angina. Patients who are given IV epinephrine must be on a cardiac monitor, with resuscitation equipment immediately available. Other adverse effects include excitability, fear, anxiety, and restlessness. In addition, the nurse should be alert to the possibility that the anaphylactic response may recur and necessitate repeated treatment. For this reason, steroids are commonly ordered and are slowly tapered over days to weeks to prevent recurrence. Examples of steroids are hydrocortisone sodium succinate, prednisone, and methylprednisolone. Patient education should include strict avoidance of the agents responsible for the anaphylactic reaction and follow-up care with a physician. For some patients, such as those with severe allergic responses to bee stings, the physician may prescribe an epinephrine kit or pen to be carried with the patient for self-medication in the event of contact with the antigen. Proper patient education regarding the use of the kit or pen is essential. See Chapters 18 and 41 for more information.

Albuterol

Albuterol is a beta-adrenergic bronchodilator used to reverse bronchoconstriction in anaphylactic shock, **asthma** (inflammation and narrowing of the airways caused by enhanced responsiveness of the tracheobronchial system to a variety of stimuli), and COPD. In emergency situations, it is typically administered via nebulizer (adults: 0.5 mL of 0.5% inhalation solution in 2.5 mL saline). Albuterol is also supplied as a metered-dose inhaler, which the patient can carry to self-administer a "rescue" dose of the drug during an acute episode of bronchospasm. The nurse should assess breath sounds before and after administration; effectiveness is evidenced by relief of bronchospasm. In severe bronchospasm, wheezing may not be audible. As the bronchospasm is relieved, wheezing may become more pronounced, indicating that the drug is producing the desired therapeutic effect. Assessment of the patient's subjective feelings of respiratory distress before and after administration is especially important. Adverse effects of albuterol include tachycardia, tremor, nervousness, cardiac dysrhythmias, and hypertension.

Diphenhydramine Hydrochloride

Diphenhydramine, an antihistamine, is often administered with epinephrine to treat anaphylactic shock. This agent is effective for treating the histamine-induced tissue swelling and pruritus common to severe allergic reactions. The standard adult dose is 25 to 50 mg administered IV or deep IM. Oral pill and liquid forms of the drug exist, but the parenteral form is preferred in emergencies. However, the patient may be instructed to keep an oral formulation on hand in the home setting for emergency self-administration during an allergic reaction prior to receiving medical assistance. An important tip for patient teaching is that the liquid diphenhydramine is easier to swallow than a pill, especially in the presence of tissue edema in the mouth or throat. Adverse effects include drowsiness, sedation, confusion, vertigo, excitability, hypotension, tachycardia, GI disturbances, and dry mouth (see Chapter 40).

Dextrose 50%

Dextrose 50% is a concentrated, high-carbohydrate solution given to treat insulin-induced hypoglycemia or insulin shock. When insulin shock is known or suspected and the patient's state of consciousness is impaired such that oral administration of sugar solutions is contraindicated, 50 mL of dextrose 50% is commonly ordered and given as an IV bolus. Dextrose 50% is highly irritating to veins and should be administered in a large peripheral or central vein whenever possible. Phlebitis can occur. Extravasation of the solution can cause tissue sloughing and necrosis. The nurse must monitor the patient's blood sugar carefully; hyperglycemia is common, especially after rapid injection. Urine output should be accurately

TABLE 59-3 AGENTS FOR EMERGENCY TREATMENT OF SHOCK

GENERIC	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
albuterol	A: nebulizer: 0.5 mL of 0.5% inhalation solution in 2.5 mL saline	For bronchoconstriction secondary to anaphylactic shock, asthma, and COPD. Adverse effects include tachycardia, tremor, nervousness, cardiac dysrhythmias, and hypertension. Pregnancy category: C; PB: UK; t½: 3.7-5 h
dextrose 50%	A: IV: 50 mL C: 0.5-1.0 g/kg IV of dextrose 25% sol	For insulin shock; severe hypoglycemia. Pregnancy category: C; PB: UK; t½: UK
diphenhydramine	IM/IV: 25-50 mg	For anaphylactic shock; acute allergic reaction. Pregnancy category: C; PB: 98%-99%; t½: 3-8 h
dobutamine	IV: drip: 2-20 mcg/kg/min	For low cardiac output. Effects antagonized by beta blockers. Pregnancy category: C; PB: UK; t½: 2 min
dopamine HCl	See Prototype Drug Chart 59-4.	
epinephrine	IM/subQ: 0.2-0.5 mg (1:1000 sol) IV/IO: 0.1-0.25 mg (1:10,000 sol) ETT: 2-2.5 mg diluted in 10 mL normal saline	For anaphylactic shock; severe acute asthmatic attack. May cause hypertensive crisis with MAOIs, increased dysrhythmias with cardiac glycosides. Pregnancy category: C; PB: UK; t½: UK
glucagon	subQ/IM/IV: 0.5-1 mg; may repeat once	Insulin shock; severe hypoglycemia; beta blocker overdose (reverses effects of beta blockers). Pregnancy category: B; PB: UK; t½: 3-10 min
norepinephrine	IV: drip: 0.5-30 mcg/min (titrated)	Hypotension not responsive to other therapies. Pregnancy category: D; PB: UK; t½: UK

A, Adult; *C,* child; *COPD,* chronic obstructive pulmonary disease; *ETT,* endotracheal tube; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *MAOIs,* monoamine oxidase inhibitors; *min,* minute; *PB,* protein-binding; *sol,* solution; *subQ,* subcutaneous; *t½,* half-life; *UK,* unknown.

recorded, because osmotic diuresis can occur when blood sugar is elevated, and a hyperosmolar state can result. Patient education must be centered on teaching about diabetes, nutrition, physical activity, and insulin administration.

Pediatric Implications

Glycogen stores in infants and children may be quickly depleted in stress states produced by severe illness. Because adequate amounts of glucose are essential to strong myocardial function, hypoglycemia must be corrected to provide the greatest chance for successful resuscitation. After determining that hypoglycemia is present by the fingerstick or heelstick method of rapid blood glucose testing, dextrose 25% or less may be administered per physician order. Because glucose is supplied in a 50% concentration, it must be diluted 1:1 in sterile water before administration to reduce its osmolarity and prevent sclerosis of peripheral veins. The standard dose is 0.5 to 1g/kg IV or IO.

Glucagon

Glucagon is a pancreas-produced hormone that elevates blood sugar by stimulating glycogen breakdown (**glycogenolysis**). Glucagon, like dextrose 50%, is indicated in the treatment of severe insulin-induced hypoglycemia or insulin shock. In an emergency when dextrose 50% is unavailable or cannot be administered IV, glucagon is an effective agent. Glucagon may be given subQ, IM, or IV. The standard dose for adults and children is 0.5 to 1 mg, which can be repeated in 15 minutes for persistent coma. If the coma has not resolved after two doses, dextrose 50% must be administered. Adverse effects from glucagon are uncommon, but can include nausea, vomiting, and a hypersensitivity reaction that may produce bronchospasm and respiratory distress. Glucagon can also be used as an agent to reverse the effects of calcium channel blocker and beta-blocker overdose; in this situation, 5 to 10 mg IV of glucagon is administered initially, followed by an IV infusion of 3 to 5 mg/hr.

Table 59-3 lists the emergency drugs for shock and their dosages, uses, and considerations.

EMERGENCY DRUGS FOR HYPERTENSIVE CRISES AND PULMONARY EDEMA

A variety of pharmacologic agents may be prescribed to treat **hypertensive crisis,** generally defined as a diastolic blood pressure that exceeds 110 to 120 mm Hg, and pulmonary edema. Three of the most commonly prescribed drugs are discussed in this section. The drugs are cross-referenced to their specialty chapter.

Labetalol

Labetalol is an alpha- and beta-adrenergic blocker that acts by inhibiting the effects of the sympathetic nervous system. Its pharmacologic actions include lowering heart rate, blood pressure, myocardial contractility, and myocardial oxygen consumption, and reducing the vasoconstriction that results from sympathetic nervous system stimulation. This agent is indicated for the acute management of clinically significant hypertension in the presence of ischemic and hemorrhagic stroke, as well as for hypertensive crisis.

Initially 10 to 20 mg of labetalol is administered IV push over 2 minutes. This starting dose can be repeated or doubled every 10 minutes until the desired clinical response is achieved, to a maximum dose of 300 mg. As an alternative approach, a continuous infusion of labetalol mixed with D_5W can be prepared to deliver 2 mg/min until the target therapeutic response is attained; the maximum dose with this approach is also 300 mg.

Important nursing considerations during the administration of labetalol include the use of an electronic infusion pump for accurate continuous infusion medication delivery, cardiac monitoring, and frequent blood pressure measurement. Documentation of blood pressure may need to be as often as every 5 minutes during IV push dosing or at the initiation of the continuous infusion. Serious adverse effects include hypotension, bradycardia, ventricular dysrhythmias, and bronchospasm. Dizziness is also a frequently reported adverse reaction. Labetalol is contraindicated in patients with bronchial asthma or COPD because of the risk of bronchospasm and in patients with severe bradycardia or apparent heart failure.

Nitroprusside Sodium

Nitroprusside sodium is an IV agent used to reduce arterial blood pressure in hypertensive emergencies. The mechanism of action is immediate direct arterial and venous vasodilation. Antihypertensive effects end when nitroprusside sodium is discontinued; blood pressure increases as soon as drug administration is stopped. Continuous and accurate blood pressure measurement is required. In general, 50 mg of nitroprusside sodium is mixed in 250 mL D_5W. The typical dose range for adults is 0.25 to 5 mcg/kg/min, titrated to the desired clinical response. The maximum dose is 10 mcg/kg/min.

There are several important nursing considerations:

- Nitroprusside sodium is rapidly inactivated by light; the IV bottle or bag must be wrapped with aluminum foil or another opaque material to protect the solution from degradation.
- Although a faint brown tint is typical, blue or brown discoloration of the solution indicates degradation and necessitates that the solution be discarded.
- When nitroprusside sodium therapy is prolonged, or infused at the maximum dose of 10 mcg/kg/min for more than 10 minutes, patients are at risk for toxicity resulting from elevated serum thiocyanate or cyanide levels (by-products of drug metabolism). Signs and symptoms include metabolic acidosis, profound hypotension, dyspnea, dizziness, and vomiting. Serum thiocyanate levels should be monitored every 24 to 72 hours for patients receiving prolonged infusions of more than 2 mcg/kg/min. Patients with renal insufficiency or failure are at a higher risk, because the metabolites are excreted in the urine.
- Patients should be placed on an oral antihypertensive agent as soon as possible so that nitroprusside sodium can be tapered slowly. Drug data for nitroprusside sodium are presented in Prototype Drug Chart 59-5.

PROTOTYPE DRUG CHART 59-5

Nitroprusside Sodium

Drug Class Vasodilator Trade Name: Nipride Pregnancy Category: C	**Dosage** A: IV: Drip: 0.25-5 mcg/kg/min; begin at 0.25 mcg/kg/min, and titrate to desired effect
Contraindications Hypersensitivity, hypertension (compensatory), decreased cerebral perfusion, coarctation of the aorta Caution: Increased intracranial pressure	**Drug-Lab-Food Interactions** Drug: Antihypertensives, general anesthetics Note: Do not mix with any other drug in syringe or solution. Lab: Decrease in PCO_2, Ph
Pharmacokinetics Absorption: IV only Distribution: PB: UK Metabolism: t½: <10 mi Excretion: In urine	**Pharmacodynamics** IV: Onset: 1-2 min Peak: Rapid Duration: 1-10 min
Therapeutic Effects/Uses To treat hypertensive crisis and to decrease systemic vascular resistance to improve cardiac performance Mode of Action: Stimulates smooth muscle of veins and arteries; produces peripheral vasodilation	
Side Effects Dizziness, headache, nausea, abdominal pain, sweating, palpitations, weakness, vomiting	**Adverse Reactions** Thiocyanate toxicity: hypotension, tinnitus, dyspnea, blurred vision, metabolic acidosis Life-threatening: Severe hypotension, loss of consciousness, profound cardiovascular depression

A, Adult; *IV,* intravenous; *min,* minute; *PB,* protein-binding; *PCO2,* partial pressure of carbon dioxide; *t ½,* half-life; *UK,* unknown; *<,* less than.

TABLE 59-4 EMERGENCY DRUGS FOR HYPERTENSIVE CRISES AND PULMONARY EDEMA

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
nitroprusside sodium	See Prototype Drug Chart 59-5.	
furosemide (Lasix)	IV: Initial bolus of 0.5-1.0 mg/kg over 1-2 min, up to 2 mg/kg	For acute pulmonary edema from left ventricular dysfunction; hypertensive crisis. Adverse effects: hypovolemia, dehydration, electrolyte disturbances
morphine	IV: 1-4 mg q5-30min	For pulmonary edema, chest pain, unstable angina, MI
labetalol hydrochloride	IV: Initial push 10-20 mg over 2 min, repeated or doubled q10min up to a max of 300 mg; continuous infusion 2 mg/min	For hypertension in CVA and for hypertensive crisis. Adverse effects: ventricular dysrhythmias, hypotension, bronchospasm. Contraindications: bronchial asthma, COPD, severe bradycardia, heart failure

COPD, Chronic obstructive pulmonary disease; *CVA,* cerebrovascular accident; *IV,* intravenous; *max,* maximum; *MI,* myocardial infarction; *min,* minute.

Furosemide

Furosemide (Herbal Alert 59-2) is classified as a *loop diuretic* that acts by inhibiting sodium and chloride reabsorption from the ascending loop of Henle and the proximal and distal tubules. It promotes the renal excretion of water, sodium, chloride, magnesium, hydrogen, and calcium, and it depletes potassium. Furosemide also has peripheral and renal vasodilating effects that can lower blood pressure. The main indications for use of furosemide as an emergency drug are acute pulmonary edema from left ventricular dysfunction and hypertensive crisis.

HERBAL ALERT 59-2

Furosemide

Ginseng can inhibit its efficacy. Licorice can promote potassium loss, enhancing the potential for severe hypokalemia. These herbs should not be taken concurrently with furosemide.

Furosemide is given as an initial bolus of 0.5 to 1 mg/kg IV over 1 to 2 minutes. For patients who take furosemide on a regular basis, the effective dose may be much higher (up to 2 mg/kg). The vasodilatory effects occur *before* diuresis begins and act to lower blood pressure. Central venous pressure is reduced through a decrease in venous return to the heart once vasodilation is achieved. Diuresis should start within 10 minutes of drug administration and may continue for approximately 6 hours.

The most significant adverse effects are severe hypovolemia, dehydration, and electrolyte disturbances (hypokalemia, hypomagnesemia, hyponatremia, and hypochloremia). Patients on digitalis preparations are at an increased risk of digitalis toxicity from hypokalemia. The patient's fluid and electrolyte status, BUN, and creatinine must be carefully assessed before and after furosemide administration, including auscultation of breath sounds for rales, strict surveillance of intake and output, and review of laboratory data when available. An indwelling urinary catheter might be necessary. Electrolyte and careful fluid replacement may be required during furosemide therapy to prevent physiologic consequences. The nurse must also exercise caution when giving nephrotoxic agents when furosemide is prescribed and in administering the drug to patients with sulfonamide sensitivity, because furosemide is a sulfonamide derivative and can produce an allergic reaction.

Morphine Sulfate

Like furosemide, morphine sulfate is also indicated for acute pulmonary edema, because it produces venous vasodilation that decreases cardiac **preload** (the amount of blood returning to the right ventricle). The net effect is a decrease in pulmonary venous congestion. Morphine has been discussed previously in this chapter.

Table 59-4 lists emergency drugs used for hypertensive crises and pulmonary edema and their dosages, uses, and considerations.

CRITICAL THINKING CASE STUDY

DW, age 19 years, suffered a gunshot wound to the head and a spinal cord injury from a stab wound over the thoracic spine 1 hour ago. He was transported immediately from the injury scene to the trauma center by paramedics. Upon hospital arrival, DW was awake and following simple commands, but his neurologic status has subsequently deteriorated. At this point, he has undergone initial resuscitation and a rapid diagnostic workup. He is now orally intubated, has two functional IV catheters (one peripheral line in the right forearm and one triple-lumen central line in the left subclavian vein), an oral gastric tube, and an indwelling urinary catheter. His current vital signs are BP 88/56, HR 56, temperature 96.8° F (36° C), and RR 16 on a mechanical ventilator. His mother reported that DW is addicted to opioids, including heroin. He also abuses oral diazepam (Valium) and other street drugs.

DW's diagnoses include a penetrating head injury with intracerebral hemorrhage diagnosed by computed tomography (CT) scan, a penetrating spinal cord injury at the T4 level, and drug abuse. DW opens his eyes spontaneously, does not follow commands, and withdraws to pain with only his upper extremities; his lower extremities do not move.

1. On arrival to the trauma center, should DW have received supplemental oxygen based on his mechanism of injury? What type of oxygen delivery device would be appropriate for DW on his initial presentation when he was breathing spontaneously?
2. The physician orders 50 g of mannitol to be given now, IV push. On hand are several 50-mL vials of "mannitol, 25%" solution. How many milliliters of mannitol from this vial need to be drawn up into the syringe to administer 50 g?
3. Describe the type of needle that must be used when administering mannitol. Explain your answer. What size syringe should be used? Which IV line should be used to administer the mannitol?
4. What are the indications for mannitol administration? List at least three nursing considerations when giving mannitol.
5. DW has a history of heroin and diazepam abuse. List the reversal agents that could be used if the trauma team believes recent illicit drug use may be a contributing factor to his altered mental state.
6. Because of DW's spinal cord injury, he is exhibiting signs of neurogenic shock: bradycardia, warm skin, and hypotension. What is the drug of choice that the nurse should keep at the bedside in case DW requires emergency treatment for symptomatic bradycardia? Name the drug, its mechanism of action, and dosing considerations.
7. The physician orders a dopamine infusion, 800 mg/250 mL D_5W, to be titrated to maintain systolic BP>110 mm Hg. Which IV site would be the best choice for a continuous dopamine infusion in DW?
8. What is the consequence of dopamine extravasation?
9. Describe the treatment for dopamine extravasation.
10. What vital sign parameters must be monitored while DW receives dopamine? Name at least four adverse effects of dopamine.

Antibiotics are initiated as prophylaxis for infection due to the nature of DW's penetrating injuries. Upon infusion of the antibiotic, a bodywide rash, swelling of the lips and tongue, and hypotension develop.

11. After antibiotic administration, what condition has developed in DW?
12. What are the drugs of choice to treat DW's condition now?
13. How can the nurse evaluate the effectiveness of these drugs?

NCLEX STUDY QUESTIONS

1. The nurse is administering atropine 0.3 mg IV to a 75-year-old patient with a heart rate of 45, and his heart rate decreases to 38. What is the most likely explanation?
   a. Atropine exerts its effects by stimulating the vagus nerve.
   b. The ordered dose was too low.
   c. Adenosine was indicated, not atropine.
   d. Atropine typically slows heart rate first and then increases it.
2. An 80-year-old woman with a hip fracture received morphine 3 mg IV 20 minutes ago. The patient's son runs to the nurses' station and says that his mother is no longer responding to him. What actions should the nurse take?
   a. Assess the patient; call for additional assistance; support breathing with a bag-valve-mask device as indicated, and prepare to administer flumazenil.
   b. Call the physician and report that the patient most likely suffered a stroke and now has elevated intracranial pressure; prepare to administer mannitol.
   c. Assess the patient; call for additional assistance; support breathing with a bag-valve-mask device as indicated, and prepare to administer naloxone.
   d. Explain to the patient's son that the morphine is taking effect and that unresponsiveness is the desired outcome to best manage her pain.
3. The nurse is caring for a 21-year-old woman with a closed head injury. Her intracranial pressure is 35 (normal <20). Her serum osmolality is 330. The nurse should anticipate which action?
   a. Administer mannitol.
   b. Withhold mannitol at this time, but take other measures to reduce intracranial pressure.
   c. Administer sodium nitroprusside.

   d. Take no action at this time because the patient has a serum osmolality of 330, which will offset the effects of the elevated intracranial pressure.

4. A dopamine infusion was started in a patient's antecubital vein during resuscitation after cardiac arrest. The electronic infusion device is now sounding an alert for an occlusion. What is the most important immediate concern for the nurse?
   a. Infiltration with phentolamine will be necessary if there is extravasation.
   b. An interruption in the infusion can produce hypotension in the patient.
   c. The device will need to be reported to the hospital's clinical engineering department for service.
   d. The patient could develop hypertension as a result of the alarm.
5. Adenosine is ordered for a patient in the emergency department. Immediately after intravenous administration, the nurse observes a short period of asystole on the cardiac monitor that resolves spontaneously. What is the most appropriate initial action for the nurse?
   a. Call for the doctor.
   b. Prepare epinephrine and atropine for intravenous administration.
   c. Initiate CPR.
   d. Closely observe the patient and the cardiac monitor.
6. A patient on the medical-surgical unit has suffered an acute anaphylactic reaction during infusion of an IV antibiotic with hives and bronchospasm. The nurse practitioner has written a number of stat medication orders. What is the priority medication to administer first?
   a. steroid dose pack
   b. dopamine
   c. epinephrine
   d. diphenhydramine
7. The nurse receives a stat order to administer 50% dextrose solution intravenously to a 1-year-old child with hypoglycemia. How should this medication best be prepared for safe administration to the child?
   a. Use a filter needle.
   b. Draw the medication into a tuberculin syringe.
   c. Dilute 1 : 1 with sterile water to produce dextrose 25%.
   d. Shake the solution vigorously before injection.
8. A 51-year-old woman has been reportedly taking Xanax for a severe anxiety disorder following her mother's death. She was brought into the emergency department because she became unresponsive while at work in an insurance office. Knowing her history, what should the nurse anticipate administering?
   a. mannitol
   b. naloxone
   c. activated charcoal
   d. flumazenil
9. A 25-year-old woman was admitted to the emergency department after a successful prehospital resuscitation from cardiac arrest owing to an asthma attack. On arrival, her pulse oximeter reading is 85%. Given her condition, what is the most important initial medication to administer as ordered?
   a. epinephrine
   b. sodium bicarbonate
   c. albuterol
   d. oxygen
10. The nurse practitioner orders epinephrine 0.3 mg IM for a severe allergic reaction to a bee sting in an adult patient. Which concentration of epinephrine should the nurse select to administer this particular dose?
    a. 1 : 10,000
    b. 1 : 1000
    c. 1 : 100
    d. 1 : 10
11. The emergency physician orders activated charcoal for a teenage girl who took an intentional overdose of aspirin and several unknown drugs from her parent's medicine cabinet. Upon preparing to administer the activated charcoal by mouth, the nurse notes that the patient has become very somnolent and opens her eyes only to a noxious stimulus. Which action by the nurse is most appropriate at this point?
    a. Immediately discuss the change in the patient's mental status with the physician so that the plan of care can be reevaluated.
    b. Immediately insert a nasogastric tube, and administer the activated charcoal.
    c. Immediately elevate the head of the patient's stretcher, and coax her to drink the activated charcoal while applying noxious stimuli as necessary to keep her awake.
    d. Give only half the dose now, and wait until her mental status improves before giving the remainder of the dose.
12. While getting dressed to go home after minor outpatient surgery on his leg for removal of a mole, a 62-year-old patient notifies the nurse that he has severe chest pain. He is also diaphoretic and complains of shortness of breath. The surgeon is notified and orders administration of aspirin 325 mg PO while quickly making arrangements to transfer the patient to the emergency department. Which is the best course of action by the nurse?
    a. Question the aspirin order because the patient just had a surgical procedure and might have bleeding complications.
    b. After checking for drug allergies, first instruct the patient to chew the aspirin tablet and then administer the aspirin.
    c. After checking for drug allergies, instruct the patient to swallow the aspirin tablet whole.
    d. Suggest to the surgeon that the enteric-coated form of aspirin might be better tolerated by the patient to avoid GI distress.

Answers: 1, b; 2, c; 3, b; 4, b; 5, d; 6, c; 7, c; 8, d; 9, d; 10, b; 11, a; 12, b.

APPENDIX

A

Therapeutic Drug Monitoring*

Selected drugs are monitored by serum and urine to achieve and maintain therapeutic drug effect and to prevent drug toxicity. Drugs with a wide therapeutic range (window), the difference between effective dose and toxic dose, are not usually monitored. Drug monitoring is important in maintaining a drug concentration–response relationship, especially when the serum drug range (window) is narrow, such as with digoxin and lithium. Therapeutic drug monitoring (TDM) is the process of following drug levels and adjusting them to maintain a therapeutic level. Not all drugs can be dosed and/or monitored by their blood levels alone.

Drug levels are obtained at peak time and trough time after a steady state of the drug has been achieved in the patient. Steady state is reached after four to five half-lives of a drug and can be reached sooner if the drug has a short half-life. Once steady state is achieved, the serum drug level is checked at the peak level (maximum drug concentration) and/or at trough/residual level (minimum drug concentration). If the trough or residual level is at the high therapeutic point, toxicity might occur. Careful assessment is needed by both physical and laboratory means.

TDM is required for the following:

- Drugs with a narrow therapeutic index or range (window)
- When other methods for monitoring drugs are not effective, such as blood pressure (BP) monitoring
- To determine when adequate blood concentrations are reached
- To evaluate a patient's compliance to drug therapy
- To determine whether other drugs have altered serum drug levels (increased or decreased) that could result in drug toxicity or lack of therapeutic effect
- To establish a new serum drug level when the dosage is changed

Drug groups for TDM include analgesics, antibiotics, anticonvulsants, antineoplastics, bronchodilators, cardiac drugs, hypoglycemics, sedatives, and tranquilizers. To effectively conduct TDM, the laboratory must be provided with the following information: drug name and daily dosage, time and amount of last dose, time blood was drawn, route of administration, and patient's age. Without complete information, serum drug reporting might be incorrect.

HIV drugs are primarily dosed based on the patient's viral load or CD4 counts. Many of these drugs have dosage adjustments for renal and/or hepatic impairment.

---

*Revised by Ronald J. Lefever, RPh, Lead Pharmacist, VCU Medical Center, Richmond, Virginia.

DRUG	THERAPEUTIC RANGE	PEAK TIME	TOXIC LEVEL
acetaminophen (Tylenol)	10-20 mcg/mL	1-2.5 h	>50 mcg/mL Hepatotoxicity: >200 mcg/mL
acetohexamide (Dymelor)	20-70 mcg/mL (dosed according to blood glucose levels)	2-4 h	>75 mcg/mL
alcohol	Negative		Mild toxic: 150 mg/dL Marked toxic: >250 mg/dL
alprazolam (Xanax)	10-50 ng/mL	1-2 h	>75 ng/mL
amikacin (Amikin)	Peak: 20-30 mcg/mL Trough: <10 mcg/mL	Intravenously: 0.5 h Intramuscular: 0.5-1.5 h	Peak: >35 mcg/mL Trough: >10 mcg/mL
aminocaproic acid (Amicar)	100-400 mcg/mL	1 h	>400 mcg/mL
aminophylline (see theophylline)			
amiodarone (Cordarone)	0.5-2.5 mcg/mL	2-10 h	>2.5 mcg/mL
amitriptyline (Elavil) + nortriptyline (parent and active metabolite)	110-225 ng/mL	2-4 h (and up to 12 h)	>500 ng/mL
amobarbital (Amytal)	1-5 mcg/mL	2 h	>15 mcg/mL Severe toxicity: >30 mcg/mL
amoxapine	20-100 ng/mL	2.5 h; steady state 2-7 d	>100 ng/mL
amphetamine: serum: urine	20-30 ng/mL	Detectable in urine after 3 h; positive for 24-48 h	0.2 mcg/mL >30 mcg/mL (urine)
aspirin (see salicylates)			
atenolol (Tenormin)	200-500 ng/mL	2-4 h	>500 ng/mL
beta carotene	48-200 mcg/dL	Several weeks	>300 mcg/dL
bromide	20-80 mg/dL		>100 mg/dL
butabarbital (Butisol)	1-2 mcg/mL	3-4 h	>10 mcg/mL
butalbital	10-20 mcg/mL		>40 mcg/mL
caffeine	Adult: 3-15 mcg/mL Infant: 8-20 mcg/mL	0.5-1 h	>50 mcg/mL
carbamazepine (Tegretol)	4-12 mcg/mL	6 h (range 2-24 h)	>9-15 mcg/mL
chloral hydrate	2-12 mcg/mL	1-2 h	>20 mcg/mL
chloramphenicol (Chloromycetin)	10-20 mg/L		>25 mg/L
chlordiazepoxide (Librium)	1-5 mcg/mL	2-3 h	>5 mcg/mL
chlorpromazine (Thorazine)	50-300 ng/mL	2-4 h	>750 ng/mL
chlorpropamide (Diabinese)	75-250 mcg/mL (Diabinese)	3-6 h	>250-750 mcg/mL
clonidine (Catapres)	0.2-2 ng/mL (hypotensive effect)	2-5 h	>2 ng/mL
clorazepate (Tranxene)	0.12-1 mcg/mL	1-2 h	>1 mcg/mL
cimetidine (Tagamet)	Trough: 0.5-1.2 mcg/mL	1-1.5 h	Trough: >1.5 mcg/mL
clonazepam (Klonopin)	10-60 ng/mL	2 h	>80 ng/mL
codeine	10-100 ng/mL	1-2 h	>200 ng/mL
cyclosporine	100-300 ng/mL	3-4 h	>400 ng/mL
dantrolene (Dantrium)	1-3 mcg/mL	5 h	>5 mcg/mL
desipramine (Norpramin)	125-300 ng/mL	4-6 h	>500 ng/mL
diazepam (Valium)	0.5-2 mg/L 400-600 ng/mL therapeutic	1-2 h	>3 mg/L >3,000 ng/mL
digitoxin (rarely administered)	10-25 ng/mL	Noticeable: 2-4 h Peak: 12-24 h	>30 ng/mL
digoxin	0.5-2 ng/mL	PO: 6-8 h IV: 1.5-2 h	2-3 ng/mL

mexiletine (Mexitil)	<0.5-2 mcg/mL	2-3 h	>2 mcg/mL
morphine	10-80 ng/mL	IV: Immediately IM: 0.5-1 h subQ: 1-1.5 h	>200 ng/mL
netilmicin (Netromycin)	Peak: 0.5-10 mcg/mL Trough: <4 mcg/mL	IV: 30 min	Peak: >16 mcg/mL Trough: >4 mcg/mL
nifedipine (Procardia)	50-100 ng/mL	0.5-2 h	>100 ng/mL
nortriptyline (Aventyl)	50-150 ng/mL	8 h	>200 ng/mL
oxazepam (Serax)	0.2-1.4 mcg/mL	1-2 h	
oxycodone (Percodan)	10-100 ng/mL	0.5-1 h	>200 ng/mL
pentazocine (Talwin)	0.05-0.2 mcg/mL	1-2 h	>1 mcg/mL Urine: >3 mcg/mL
pentobarbital (Nembutal)	1-5 mcg/mL	0.5-1 h	>10 mcg/mL Severe toxicity: >30 mcg/mL
phenmetrazine (Preludin)	5-30 mcg/mL (urine)	2 h	>50 mcg/mL (urine)
phenobarbital (Luminal)	15-40 mcg/mL	6-18 h	>40 mcg/mL Severe toxicity: >80 mcg/mL
phenytoin (Dilantin)	10-20 mcg/mL	4-8 h	>20-30 mcg/mL Severe toxicity: >40 mcg/mL
pindolol (Visken)	0.5-6 ng/mL	2-4 h	>10 ng/mL
primidone (Mysoline)	5-12 mcg/mL	2-4 h	>12-15 mcg/mL
procainamide (Pronestyl)	4-10 mcg/mL	1 h	>10 mcg/mL
procaine (Novocain)	<11 mcg/mL	10-30 min	>20 mcg/mL

Continued

DRUG	THERAPEUTIC RANGE	PEAK TIME	TOXIC LEVEL
prochlorperazine (Compazine)	50-300 ng/mL	2-4 h	>1,000 ng/mL
propoxyphene (Darvon)	0.1-0.4 mcg/mL	2-3 h	>0.5 mcg/mL
propranolol (Inderal)	>100 ng/mL	1-2 h	>150 ng/mL
protriptyline (Vivactil)	50-150 ng/mL	8-12 h	>200 ng/mL
quinidine	2-5 mcg/mL	1-3 h	>6 mcg/mL
ranitidine (Zantac)	100 ng/mL	2-3 h	>100 ng/mL
reserpine (Serpasil)	20 ng/mL	2-4 h	>20 ng/mL
salicylates (aspirin)	10-30 mg/dL	1-2 h	Tinnitus: 20-40 mg/mL Hyperventilation: >35 mg/dL Severe toxicity: >50 mg/dL
secobarbital (Seconal)	2-5 mcg/mL	1 h	>15 mcg/mL Severe toxicity: >30 mcg/mL
streptomycin	Peak: 5-20 mcg/mL Trough: <5 mcg/mL		Peak: >40 mcg/mL Trough: >40 mcg/mL
sulfadiazine	100-120 mcg/mL		>300 mcg/mL
sulfamethoxazole	90-100 mcg/mL		>300 mcg/mL
sulfapyridine	75-90 mcg/mL		>300 mcg/mL
sulfisoxazole	90-100 mcg/mL		>300 mcg/mL
theophylline (Theo-Dur)	10-20 mcg/mL	PO: 2-3 h IV: 15 min (depends on smoking or nonsmoking)	>20 mcg/mL
thiocyanate	4-20 mcg/mL		>60 mcg/mL
thioridazine (Mellaril)	100-600 ng/mL 1-1.5 mcg/mL	2-4 h	>2000 ng/mL >10 mcg/mL
timolol (Blocadren)	3-55 ng/mL	1-2 h	>60 ng/mL
tobramycin (Nebcin)	Peak: 5-10 mcg/mL Trough: 1-1.5 mcg/mL	IV: 15-30 min IM: 0.5-1.5 h	Peak: >12 mcg/mL Trough: >2 mcg/mL
tocainide (Tonocard)	4-10 mcg/mL	0.5-3 h	>12 mcg/mL
tolbutamide (Orinase)	80-240 mcg/mL	3-5 h	>640 mcg/mL
trazodone (Desyrel)	500-2,500 ng/mL	1-2 wk	>4,000 ng/mL
triamcinolone (Aristocort, Kenalog)	135-637 nmol/L at 8 AM	1-2 h (PO/IM)	>700 nmol/L at 8 AM
trifluoperazine (Stelazine)	50-300 ng/mL	2-4 h	>1,000 ng/mL
trimethoprim/sulfamethoxazole (TMP/SMX)	Peak: trimethoprim: >5 mcg/mL Peak: sulfamethoxazole: >100 mcg/mL		
valproic acid (Depakene)	50-100 mcg/mL	0.5-1.5 h	>100 mcg/mL Severe toxicity: >150 mcg/mL
vancomycin (Vancocin)	Peak: 20-40 mcg/mL Trough: 5-10 mcg/mL	IV: Peak: 5 min IV: Trough: 12 h	Peak: >80 mcg/mL
verapamil (Calan)	100-300 ng/mL	PO: 1-2 h IV: 5 min	>500 ng/mL
warfarin (Coumadin)	1-10 mcg/mL (dose usually adjusted by PT 1-2.5 control) or INR: 2-3	1.5-3 d	>10 mcg/mL INR: >4

d, Day; *h,* hour; *min,* minute; *wk,* week; >, greater than; <, less than.

HIV DRUGS

DRUG	PEAK TIME (TMAX)	ELIMINATION HALF-LIFE	NEW TO TDM	SPECIAL CONSIDERATIONS
Nucleoside/Nucleotide Reverse Transcriptase Inhibitors (NRTIs)				
abacavir (Ziagen)	0.7-1.7 h	1.5 h		Dose adjustment for hepatic impairment
abacavir + lamivudine + zidovudine (Trizivir)	See individual agents	See individual agents		
didanosine (Videx)	0.25-1.5 h	1.5 h		
emtricitabine (Emtriva)	1-2 h	10 h	Y	
emtricitabine + Tenofovir (Truvada)	1-2 h	10-17 h	Y	
lamivudine (Epivir)	0.9-3.2 h	5-7 h		Dose adjustment for renal impairment suggested
lamivudine + abacavir (Epzicom)	See individual agents	1.5-7 h	Y	Abacavir: $t\frac{1}{2}$: 1.5 h; lamivudine: $t\frac{1}{2}$: 5-7 h Dose adjustment for renal impairment required
lamivudine + zidovudine (Combivir)	See individual agents		Y	
stavudine (Zerit)	1-1.5 h	1.5 h (8 h with renal impairment)		
tenofovir (Viread)	1 h	17 h	Y	Dose adjustment for renal impairment required
zidovudine (Retrovir)	0.5-1.5 h	1 h (1.4-2.9 h with renal impairment)		
Non-Nucleoside Reverse Transcriptase Inhibitors (NNRTIs)				
delavirdine (Rescriptor)	1 h	2-11 h	Y	
etravirine (Intelence)	2.5-4 h	41 h	Y	NRTI and first-line NNRTI (delavirdine, efavirenz, or nevirapine) experienced or contraindicated, with either detectable viral load or intolerance to current regimen
efavirenz (Sustiva)	3-5 h	40-55 h		
nevirapine (Viramune)	4 h	25-30 h		
Multiclass Combination Agents				
efavirenz + emtricitabine + tenofovir (Atripla)	See individual agents	See individual agents	Y	
Protease Inhibitors (PIs)				
atazanavir (Reyataz)	2.5 h	7 h	Y	
darunavir (Prezista)	2.5-4 h	15 h	Y	Elimination half-life when co-administered with ritonavir.
fosamprenavir (Lexiva)	1.5-4 h	7.7 h	Y	
indinavir (Crixivan)	0.8 h	2 h (3 h with hepatic impairment)		
lopinavir + ritonavir (Kaletra)	4 h	5-6 h		
ritonavir (Norvir)	2-4 h	3-5 h		
tipranavir (Aptivus)	2.9-3 h	5.5-6 h	Y	Female and male, respectively
maraviroc (Selzentry)	0.5-4 h	14-18 h	Y	NRTI and NNRTI experienced or contraindicated and prior experience with one or more PIs, or raltegravir, or intolerance to current regimen
Integrase Inhibitor				
raltegravir (Isentress)	3 h	9 h	Y	

h, Hour; $t\frac{1}{2}$, half-life.

APPENDIX B

Selected Potential Weapons of Bioterrorism

Refer to the following online resources for updates to this information:

- Journal of the American Medical Association (JAMA): *www.jama.ama-assn.org/cgi/collection/bioterrorism*
- U.S. Food and Drug Administration (FDA): *www.fda.gov/oc/opacom/hottopics/bioterrorism.html*

AGENT/ETIOLOGY	TRANSMISSION/CLINICAL MANIFESTATIONS	DRUG TREATMENT/CONSIDERATIONS
Bacteria and Viruses		
Anthrax, pulmonary/*Bacillus anthracis*	Inhalation of spores; incubation up to 60 d Initially ILS: fever, malaise, fatigue, nonproductive cough, chest discomfort. Later, (2 to 3 d) severe respiratory distress, stridor, cyanosis, septicemia, increased fever, and hemorrhagic meningitis	Early treatment with antibiotics IMPORTANT; IV route preferred; ciprofloxacin and doxycycline drugs of choice; PLUS use of additional antibiotics to avoid drug resistance in both adults and children; duration for IV and PO 60 d. Low morbidity when treated early; with onset of respiratory distress, morbidity near 100%. Recombinant vaccine in development
Anthrax, cutaneous/*Bacillus anthracis*	Spores enter through nonintact skin; incubation up to 60 d; papule becomes fluid-filled vesicle that dries and forms dark eschar	Ciprofloxacin or doxycycline PO for 7 to 10 d; with systemic symptoms or risk of inhalation, treat as above. Morbidity up to 24% if untreated; treated <1%. Goal: prevention of systemic complications
Smallpox/variola virus	Respiratory droplets and pustule drainage; incubation 12 to 14 d; prodrome 2 to 4 d of ILS; papular rash that becomes deep vesicles, then scabs; mostly face and extremities; does involve palms and soles	Supportive; research continues on new antivirals (e.g., cidofovir); proven treatment unknown. Treat corneal lesions with idoxuridine; vaccinate patient, all contacts, and health care workers in facility. Antibiotics for secondary infections. Morbidity: 30% likely; in rare hemorrhagic form: up to 90%. *For terrorist attack:* Follow with vaccination prophylaxis.
Plague, pneumonic/*Yersinia pestis*	Inhaled droplets; incubation: 2 to 3 d; begins as ILS; rapid 24-h progression to severe pneumonia, hemoptysis, and then respiratory distress and failure. Can be transmitted by coughing	Antibiotics of choice are streptomycin and gentamicin. In mass casualty environment, PO administration is more usual with doxycycline or ciprofloxacin. No vaccine available. Morbidity 100% if untreated
Tularemia/*Francisella tularensis*/"rabbit fever"	Inhaled or through skin; incubation 2 to 5 d (up to 14 d); begins as ILS; progresses over days to pneumonia with dyspnea and hilar adenopathy. Not transmitted person to person	Antibiotics of choice: IV streptomycin or gentamicin; po doxycycline or ciprofloxacin in mass breakout. Morbidity <5%
Viral hemorrhagic fevers; Ebola	Blood or secretions; incubation 2 to 10 d; prodrome of ILS; bleeding day 3; desquamation day 5; progresses rapidly to multisystem organ failure and delirium	Supportive care; transfusions and fresh frozen plasma; dialysis
Biotoxins		
Botulinum/*Clostridium botulinum*	Inhaled; incubation of 24 to 72 h; symmetric descending flaccid paralysis; eyes, bulbar muscles, then respiratory and skeletal effects	Supportive; antitoxin (from Centers for Disease Control and Prevention or Public Health) may decrease progress; BabyBIG for children <1 year. No antibiotics. Morbidity uncertain; long recovery

APPENDIX B Selected Potential Weapons of Bioterrorism

AGENT/ETIOLOGY	TRANSMISSION/CLINICAL MANIFESTATIONS	DRUG TREATMENT/CONSIDERATIONS
Ricin/*Ricinus communis*	Inhalation: onset within hours; coughing, chest tightness, dyspnea, nausea, and muscle ache. Later, edematous airway; cyanosis and death may follow Ingested: GI hemorrhage, vomiting, and diarrhea. Later, liver and kidney failure; may die within 10 to 12 d Injection: severe symptoms and death; route unlikely to terrorists	Supportive; no antidote for ricin. Vaccine in development
Chemical Weapons		
Nerve agents (e.g., Sarin, VX, GA, GB)	Absorbed through skin and mucous membranes and inhaled; onset rapid when inhaled; skin or mucous membrane onset 30 min to 18 h. Early signs: eye pain, rhinorrhea, and local sweating if droplet. Classic toxidrome: diarrhea, urination, miosis, bronchospasm, bronchorrhea, bradycardia, emesis, lacrimation, and salivation	Mechanical ventilation support with oxygen. Atropine IV or IM in high doses: 2 mg q3-5min; pralidoxime chloride (2-PAM) 1 to 2 g IV over 30 to 60 min; may need drip of 500 mg over 24 h; valium or Versed PRN for seizures; homatropine for ciliary spasm. Morbidity potentially high, depending on concentration and duration of exposure
Chlorine or phosgene	Inhaled, mucous membranes, and eyes; rapid irritant effects; pulmonary effects (distress and edema) may be seen in 6 to 24 h	Humidified oxygen; bronchodilators; ventilatory support with PEEP for ARDS; monitor for 24 h if suspected significant exposure. Morbidity depends on exposure level; phosgene higher than chlorine
Sulfur mustard (Mustard gas)	Mainly absorbed through skin; can affect airway, eyes, GI tract, and bone marrow. Delayed onset of >6 h with few warning symptoms of contact; blistering of affected areas. Later, seizures and dysrhythmias	Requires rapid decontamination. Intubation if severe airway damage. Wash with dilute sodium thiosulfate (2.5% solution); prednisone may have antidote effects; Neupogen for later leukopenia. Morbidity under 5% to 10%
Cyanide	Absorbed in GI tract via contaminated products; inhaled vapors or via skin; generally rapid onset of symptoms; delayed if low concentration; sudden loss of consciousness with high concentration; cyanosis and severe respiratory distress	Inhaled amyl nitrite, sodium nitrite IV, sodium thiosulfate. Morbidity varies by exposure level
Radiologic Agents		
Nuclear bombs	Immediate threat: blast Delayed threat: radioactive fallout	Potassium iodide blocks uptake by thyroid of radioactive iodine, thus reducing risk of cancer; tablets for this purpose are released by public health after determining the presence of iodine-131. FDA recommended doses: Birth to 1 mo: 16 mg; >1 mo to 3 y: 32 mg; >3 y to 18 y: 65 mg; >18 y or lactating: 130 mg

ARDS, Adult respiratory distress syndrome; *d,* day; *FDA,* Food and Drug Administration; *GI,* gastrointestinal; *h,* hour; *ILS,* influenza-like syndrome; *IM,* intramuscular; *IV,* intravenous; *min,* minute; *mo,* month; *PEEP,* positive end-expiratory pressure; *PO,* by mouth; *PRN,* as needed; *y,* year; *>,* greater than; *<,* less than.

  nursing interventions, 682
  planning, 682
Patient-centered collaborative care, antifungals, 444
  assessment, 444
  evaluation, 445
  nursing diagnosis, 444
  nursing interventions, 444-445
  planning, 444-445
Patient-centered collaborative care, anti-glaucoma drugs, 718-720
  assessment, 718-719
  evaluation, 720
  nursing diagnoses, 719
  nursing interventions, 719-720
  planning, 719
Patient-centered collaborative care, antimalarials, 455-457
  assessment, 455
  evaluation, 457
  nursing diagnoses, 455
  nursing interventions, 455-457
  planning, 455
Patient-centered collaborative care, antiparkinsonism, 315-317
  assessment, 315-316
  evaluation, 317
  nursing diagnoses, 316
  nursing interventions, 316-317
  planning, 316
Patient-centered collaborative care, antiretroviral therapy, 483-485
  assessment, 483
  evaluation, 485
  nursing diagnoses, 484
  nursing interventions, 484
  planning, 484
Patient-centered collaborative care, antitubercular drugs, 439-440
  assessment, 439-440
  evaluation, 440
  nursing diagnoses, 440
  nursing interventions, 440
  planning, 440
Patient-centered collaborative care, atropine, 275-277
  assessment, 275-276
  evaluation, 277
  nursing diagnoses, 276
  nursing interventions, 276-277
  planning, 276
Patient-centered collaborative care, benzodiazepines, 294-296, 381-383
  assessment, 294-295, 381
  evaluation, 296, 383
  nursing diagnoses, 295, 381
  nursing interventions, 295-296, 382-383
  planning, 295, 382
Patient-centered collaborative care, beta blockers, 637-639
  assessment, 625
  evaluation, 627
  nursing diagnoses, 625-626
  nursing interventions, 626-627
Patient-centered collaborative care, betamethasone, 793
  assessment, 793
  evaluation, 793
  nursing diagnoses, 793
  nursing interventions, 793
  planning, 793
Patient-centered collaborative care, Bethanechol (Urecholine), 271-272
  assessment, 271
  evaluation, 272
  nursing diagnoses, 271
  nursing interventions, 271-272
  planning, 271
Patient-centered collaborative care, biologic response modifiers, 567-568
  assessment, 567
  evaluation, 568
  nursing diagnoses, 567-568
  nursing interventions, 568
  planning, 568
Patient-centered collaborative care, bronchodilators, 592-593
  assessment, 592
  evaluation, 593
  nursing diagnoses, 592
  nursing interventions, 592-593
  planning, 592
Patient-centered collaborative care, bulk-forming laxatives, 691
  assessment, 691
  evaluation, 691
  nursing diagnoses, 691
  nursing interventions, 691
  planning, 691
Patient-centered collaborative care, calcium, 238-239
  assessment, 238
  evaluation, 239
  nursing diagnoses, 238
  nursing interventions, 238-239
  planning, 238
Patient-centered collaborative care, cephalosporins, 409-412
  assessment, 409
  evaluation, 412
  nursing diagnoses, 412
  nursing interventions, 412
  planning, 412
Patient-centered collaborative care, Cilostazol, 671-672
  assessment, 671
  evaluation, 672
  nursing diagnoses, 672
Patient-centered collaborative care, Cilostazol *(Continued)*
  nursing interventions, 672
  planning, 672
Patient-centered collaborative care, common cold, 579-581
  assessment, 579
  evaluation, 581
  nursing diagnoses, 580
  nursing interventions, 580-581
  planning, 580
Patient-centered collaborative care, contraception (hormonal methods), 856-858
  assessment, 856
  evaluation, 858
  nursing diagnosis, 856-857
  nursing interventions, 857-858

LIST OF FEATURES

Prototype Drug Charts

15-1 Vitamin A, 214
15-2 Vitamin C, 217
15-3 Iron, 219
16-1 Potassium, 232
16-2 Calcium, 237
18-1 Epinephrine, 259
18-2 Albuterol, 260
18-3 Atenolol, 264
19-1 Bethanechol Chloride, 271
19-2 Atropine, 275
19-3 Benztropine, 276
19-4 Tolterodine Tartrate, 277
20-1 Methylphenidate, 286
21-1 Alprazolam, 295
21-2 Zolpidem Tartrate, 298
22-1 Phenytoin, 307
23-1 Carbidopa-Levodopa, 318
23-2 Rivastigmine, 323
24-1 Pyridostigmine, 328
24-2 Cyclobenzaprine, 332
25-1 Aspirin, 341
25-2 Ibuprofen, 343
25-3 Celecoxib, 345
25-4 Infliximab, 347
25-5 Allopurinol, 349
26-1 Acetaminophen, 355
26-2 Morphine Sulfate, 359
26-3 Nalbuphine, 364
26-4 Sumatriptan, 367
27-1 Fluphenazine, 374
27-2 Haloperidol and Haloperidol Decanoate, 375
27-3 Aripiprazole, 379
27-4 Lorazepam, 382
28-1 Fluoxetine, 389
28-2 Venlafaxine, 391
28-3 Lithium, 396
29-1 Amoxicillin and Dicloxacillin, 405
29-2 Ceftriaxone, 410
30-1 Azithromycin, 417
30-2 Doxycycline, 420
30-3 Gentamicin Sulfate, 423
30-4 Levofloxacin, 426
31-1 Trimethoprim-Sulfamethoxazole (TMP-SMZ), 431
32-1 Isoniazid, 438
32-2 Fluconazole, 443
33-1 Acyclovir Sodium, 452
33-2 Chloroquine HCl, 455
34-1 Nitrofurantoin, 461
35-1 Zidovudine, 475
35-2 Tenofovir, 476
35-3 Efavirenz, 477
35-4 Atazanavir, 478
36-1 Varicella, 494
37-1 Cyclophosphamide, 511
37-2 Fluorouracil, 5-Fluorouracil, 5-FU, 516
37-3 Doxorubicin, 519
37-4 Vincristine, 526
38-1 Imatinib Mesylate, 539
38-2 Erlotinib, 541
38-3 Rituximab, 549
39-1 Epoetin Alpha (Erythropoietin), 559
39-2 Filgrastim and Pegfilgrastim, 561
39-3 Sargramostim, 563
40-1 Diphenhydramine, 575
40-2 Dextromethorphan Hydrobromide, 579
41-1 Tiotropium, 589
41-2 Montelukast, 594
42-1 Digoxin, 604
42-2 Nitroglycerin, 609
42-3 Acebutolol HCl, 617
43-1 Hydrochlorothiazide, 623
43-2 Furosemide, 626
43-3 Spironolactone, 630
44-1 Metoprolol, 637
44-2 Prazosin HCl, 642
44-3 Valsartan, 647
45-1 Heparin and Warfarin Sodium, 654
45-2 Clopidogrel Bisulfate, 659
45-3 Alteplase (Tissue Plasminogen Activator [tPA]), 660
46-1 Rosuvastatin, 669
46-2 Cilostazol, 670
47-1 Promethazine HCl, 680
47-2 Diphenoxylate with Atropine, 684
47-3 Bisacodyl, 687
47-4 Psyllium, 689
48-1 Aluminum Hydroxide, 698
48-2 Ranitidine, 701
48-3 Esomeprazole, 703
48-4 Sucralfate, 705
49-1 Latanoprost, 716
50-1 Mafenide Acetate, 736
51-1 Repository Corticotropin, 745
51-2 Levothyroxine Sodium, 747
51-3 Calcitriol, 749
51-4 Prednisone, 753
52-1 Insulins, 762
52-2 Glipizide, 768
52-3 Metformin, 769
54-1 Oxytocin, 819
56-1 Conjugated Estrogens, 866
57-1 Testosterone, 874
58-1 Clomiphene Citrate, 895
59-1 Lidocaine HCl, 914
59-2 Mannitol, 917
59-3 Naloxone HCl, 918
59-4 Dopamine HCl, 920
59-5 Nitroprusside Sodium, 923

Chapter 18 Adrenergic Agonist, 260
Chapter 18 Adrenergic Neuron Blockers, 266
Chapter 19 Cholinergic Agonist, Direct Acting: Bethanechol (Urecholine), 271
Chapter 19 Anticholinergic Drugs: Atropine, 276
Chapter 20 Central Nervous System Stimulant: Methylphenidate HCl (Ritalin), 287
Chapter 21 Sedative-Hypnotic: Benzodiazepines, 294
Chapter 21 Sedative-Hypnotic: Nonbenzodiazepines, 297
Chapter 21 Anesthetics, 302
Chapter 22 Anticonvulsants: Phenytoin, 308
Chapter 23 Antiparkinson: Anticholinergic Agent, 315
Chapter 23 Antiparkinson: Dopaminergic Agent: Carbidopa-Levodopa, 320
Chapter 23 Drug Treatment for Alzheimer’s Disease: Rivastigmine, 322
Chapter 24 Drug Treatment for Myasthenia Gravis: Pyridostigmine (Mestinon), 328
Chapter 24 Muscle Relaxant: Cyclobenzaprine, 332
Chapter 25 Salicylate: Aspirin, 340
Chapter 25 Nonsteroidal Antiinflammatory Drug: Ibuprofen, 343
Chapter 25 Infliximab (Remicade), 346
Chapter 25 Antigout: Allopurinol, 348
Chapter 26 Analgesic: Acetaminophen, 356
Chapter 26 Opioid Analgesic: Morphine Sulfate, 358
Chapter 26 Opioid Agonist-Antagonist Analgesic: Nalbuphine (Nubain), 365
Chapter 27 Phenothiazines and Nonphenothiazines, 378
Chapter 27 Benzodiazepines, 381
Chapter 28 Antidepressants, 394
Chapter 28 Mood Stabilizer: Lithium, 396
Chapter 29 Antibacterials: Penicillins, 407
Chapter 29 Antibacterials: Cephalosporins, 409
Chapter 30 Antibacterials: Macrolides, 417
Chapter 30 Antibacterials: Tetracyclines, 420
Chapter 30 Antibacterials: Aminoglycosides, 422

Chapter 30 Antibacterials: Fluoroquinolones, 424
Chapter 31 Antibacterials: Sulfonamides, 432
Chapter 32 Antitubercular Drugs, 439
Chapter 32 Antifungals, 444
Chapter 33 Antiviral: Acyclovir, 453
Chapter 33 Antimalarials, 455
Chapter 33 Anthelmintics, 457
Chapter 34 Urinary Antiinfective: Nitrofurantoin, 462
Chapter 35 Antiretroviral Therapy, 483
Chapter 36 Vaccines, 496
Chapter 37 Alkylating Drugs: Cyclophosphamide, 511
Chapter 37 Antimetabolites: Fluorouracil, 515
Chapter 37 Antitumor Antibiotics: Doxorubicin, 520
Chapter 37 Plant Alkaloids: Vincristine, 523
Chapter 38 Tyrosine Kinase Inhibitors and Multikinase Inhibitors for Cancer Treatment, 541
Chapter 38 Epidermal Growth Factor/Receptor Inhibitors and Vascular Endothelial Growth Factor/Receptor Inhibitors for Cancer Treatment, 545
Chapter 38 Proteasome Inhibitors, Angiogenesis Inhibitors, and Monoclonal Antibodies for Cancer Treatment, 550
Chapter 39 Biologic Response Modifiers, 567
Chapter 40 Antihistamine: Diphenhydramine, 575
Chapter 40 Common Cold, 580
Chapter 41 Bronchodilators, 592
Chapter 41 Leukotriene Receptor Antagonists, 593
Chapter 42 Cardiac Glycosides: Digoxin, 605
Chapter 42 Antianginals, 612
Chapter 42 Antidysrhythmics, 617
Chapter 43 Diuretics: Thiazides, 624
Chapter 43 Diuretics: Loop, 627
Chapter 43 Diuretics: Potassium-Sparing, 630
Chapter 44 Antihypertensives: Beta Blockers, 637
Chapter 44 Antihypertensives: Alpha-Adrenergic Blockers, 642
Chapter 44 Antihypertensives: Angiotensin-Converting Enzyme Inhibitors, 645
Chapter 45 Anticoagulants: Warfarin and Heparin, 656
Chapter 45 Thrombolytics, 660
Chapter 46 Antihyperlipidemics (Statins), 669
Chapter 46 Vasodilators: Cilostazol, 671
Chapter 47 Antiemetics, 681
Chapter 47 Antidiarrheals, 685
Chapter 47 Laxative: Stimulant, 689
Chapter 47 Laxative: Bulk Forming, 691
Chapter 48 Antiulcer: Antacids, 698
Chapter 48 Antiulcer: Histamine$_2$ Blocker, 700
Chapter 48 Antiulcer: Pepsin Inhibitor, 703
Chapter 49 Antiglaucoma Drugs, 718
Chapter 49 Topical Antiinfectives: Ear Conditions, 724
Chapter 50 Acne Vulgaris and Psoriasis, 732
Chapter 50 Topical Antiinfectives: Burns, 737
Chapter 51 Pituitary Hormones, 745
Chapter 51 Thyroid Hormone: Replacement and Antithyroid Drugs, 750
Chapter 51 Parathyroid Hormone Insufficiencies, 752
Chapter 51 Adrenal Hormone: Glucocorticoids, 755
Chapter 52 Antidiabetics: Insulin, 764
Chapter 52 Oral Antidiabetics, 770
Chapter 53 Antepartum Drugs, 787
Chapter 53 Beta$_2$-Adrenergic Agonists: Terbutaline, 791
Chapter 53 Betamethasone (Celestone), 793
Chapter 53 Gestational Hypertension, 796
Chapter 54 Pain-Control Drugs, 805
Chapter 54 Regional Anesthetics, 811
Chapter 54 Enhancement of Uterine Contractility: Oxytocins, 818
Chapter 54 Other Oxytocics: Ergonovine and Methylergonovine, 820
Chapter 54 Beractant, Calfactant, and Poractant Alfa, 823
Chapter 55 Pain Relief for Perineal Wounds and Hemorrhoids, 828
Chapter 55 Laxatives, 831
Chapter 55 Rh$_0$(D) Immune Globulin, 837
Chapter 55 Measles-Mumps-Rubella Vaccine, 838
Chapter 55 Drugs Administered to the Newborn after Delivery, 840
Chapter 55 Hepatitis B Vaccine, 841
Chapter 56 Hormonal Methods of Contraception, 856
Chapter 56 Management of Symptomatic Menopausal Women, 869
Chapter 57 Androgens, 877
Chapter 58 Infertility, 897
Chapter 58 Sexually Transmitted Infections, 905
